[1] Archives f. Experimentelle Pathol. und Pharmacol., iv. p. 42, 1875.

I placed normal urine of a healthy man in six test-tubes in an incubator at the average temperature of 100° F. for eight days under the following conditions :—

—	Condition.	Result after eight days.
Tube 1	Urine alone	Full of bacteria
" 2	Urine with bacteria and thymol (1 in 1000)	Urine clear, no bacteria
" 3	Urine with bacteria and menthol (1 in 100)	Ditto
" 4	Urine with bacteria and menthol (1 in 200)	Ditto
" 5	Urine with bacteria and menthol (1 in 500)	Ditto
" 6	Urine with bacteria and menthol (1 in 1000)	Slightly turbid; sediment: not alkaline; no smell. On 12th day bacteria.

To two tubes containing a solution of sugar, yeast was added, and to one of them five drops of a 10 per cent. solution of thymol. After four days not a trace of sugar was found in the solution, which was without the thymol, but it was full of the yeast plant, while in the tube to which the thymol had been added the yeast had settled to the bottom, and no loss of sugar by fermentation had occurred. The next requirement in order to place our theory on a scientific basis is to find some vehicle which will carry the antiseptic to the part of the hair-follicle where the fungus grows, which is far beyond the reach of ordinary remedies. That chloroform is rapidly absorbed by the cutaneous surface is well known, and an experiment by Parissot confirms the view. He found that dilatation of the pupil began five minutes after rubbing into the skin of the temple a solution of half a milligramme of atropin in twenty grammes of chloroform, while an alcoholic solution of the same strength took thirty minutes to produce any effect.[2] The question presents itself, How is the chloroform absorbed? I reply that the larger proportion is in all probability taken up by the hair-follicles and sebaceous glands. With a view to obtain some trustworthy data on this subject I have tried, imperfectly I know, to test to some extent how far a given remedy could be traced down the follicles. Accordingly I had one part of a dog's back rubbed every day for twenty-five days with the following solution :—Asphalt, half a drachm; chloroform, two drachms; olive oil, six drachms; and another part for four days with alcannin in the place of the asphalt. At the end of the time the dog was killed, and the skin that had been rubbed was removed, frozen, and cut into sections, which are now under the microscopes on the table. You will see for yourselves how far the dyes penetrated the follicles—i.e., nearly to the root of the hair,—certainly over three-fourths of the entire length of them, in the case of the asphalt. Now this I attribute to the chloroform used in the liniment. It is a solution similar to these, only with thymol or menthol, as the case may be, in the place of the colouring matter, that I have been using for the treatment of ringworm. A strength the same as above I have found to answer well in the majority of cases. The only exceptions are very young children in whom the skin is tender from previous severe treatment, or when the disease assumes one of the pustular forms. Under these conditions I would for a time lessen the quantity of both the chloroform and the thymol, or else substitute menthol for the latter. The oil is added to arrest the evaporation of the chloroform, and to prevent it from acting as an irritant. This solution I have found of great value, and I have used it both in recent and in chronic cases with success. If employed carefully in the way about to be mentioned, it quickly cleans the scalp, thereby curing the eczema, while at the same time it destroys the fungus. It encourages the growth of new hair by stimulating the cells of the papilla; and it dissolves the fatty matter that fills up the neck of the follicle. The new hair, as it rapidly shoots up, pushes out the old diseased stumps, and raises the fungus towards the surface. In this way the disease is more quickly cured than by any other method I have seen or tried, and it has the additional advantage of not destroying the hair sacs, and consequently does not leave the unsightly bald patches which undoubtedly result from the heroic treatment. Already I have had the satisfaction of seeing several cases of fifteen or eighteen months', or even of two years' duration yield to the mild treatment in six to eight weeks, and I have not considered the cure proved till several weeks of perfect freedom from the disease have been allowed to elapse after the discontinuance of the remedy.

In conclusion, I would add a word or two of instruction as to its use. First, let the part be well washed with soap and water if it is not tender. After it is dried rub the oil in gently, taking care that the friction be not too severe or too long continued, for fear of producing a mechanical eczema. After the treatment is commenced neither soap nor water should be again used. If there is the slightest tenderness let the oil be simply painted on and not rubbed. If there are scabs present remove them gently with a comb after soaking them with the oil, which must be applied to the surface beneath. It is in the chronic squamous cases that the rubbing is well borne, but it should nevertheless be done gently and for several minutes two or three times a day, in order that the part may become thoroughly soaked with the oil. If you see at any time the slightest irritation being produced, stop the rubbing, and order the application to be merely smeared on; if it still causes irritation add for a while one-third more oil, but you will find the liniment will soon be tolerated at the proper strength. No cap should be worn in the house during the treatment, as it is essential that the head be kept cool.

FURTHER RESEARCHES ON

ETHYLATE OF SODIUM IN THE TREATMENT OF NÆVUS AND OTHER FORMS OF DISEASE,

WITH OBSERVATIONS ON ETHYLATE OF POTASSIUM.

BY BENJAMIN WARD RICHARDSON, M.D., F.R.S.

(Concluded from p. 170.)

TAKING all the evidence that is before me, Dr. Brunton's experience, my own, and the facts I have been able to collect from other practitioners, I am of opinion that with patient care in its employment, sodium ethylate may be accepted as a most effective remedy for the ordinary form of nævus.

In two examples in which, as I have been informed, there was failure from it, the causes of failure were all sufficient. In one of these instances water-dressing was used to remove the scale or crust; in the other the preparation employed was made with alcohol containing water, whereby a simple caustic soda became the agent that was brought into application.

To secure success it is necessary to have a pure ethylate solution; to make the application without any poultice or water dressing; to allow the crust to loosen of itself before removing it; and, lastly, to be patient in treatment, so as to keep up the effect until the growth is entirely destroyed.

Use of the Ethylate for Removal of Tattoo Marks and so-called Mother's Marks.—Passing from the consideration of nævus I would ask permission to dwell for a few minutes on the question of the use of sodium ethylate in other forms of disease. As a minor point the ethylate is very rapid and effectual in removing tattoo marks, and it admits of being employed with promise of good results in the removal of those diffused nævi called blood-stains, or mother's marks, when they are not extremely extensive. In a future paper I hope to bring this last-named subject of treatment before the Society in a special form based on a more perfected experience than I have as yet obtained. Meantime I would offer as a practical memorandum that in treating the diffuse nævus or mark it is good practice to commence the application of the ethylate at the extreme margin of the stain, and to produce the encrustation in a line not exceeding the tenth of an inch in diameter.

The Ethylate in the Treatment of Nasal Polypus.—I have used the ethylate three times with remarkable success in the treatment of nasal polypus. In two of these cases the polypus was small, easily discernible, and readily within reach. The ethylate was applied to the pedicle of the polypus from a probe point of cotton-wool held in the blades of a long pointed curved forceps, and in both instances the growth was destroyed during the application, and was removed by after blowing of the nose, the one application suficing to effect a cure. In another case the result was not so immediate, the patient, the son of one of our professional brethren, and a university student, had suffered from polypus for two years. The polypus had twice been removed by surgical operation, but had recurred. When the young gentleman was brought to me there was a large polypus far back filling up the nasal cavity, so that the base of the growth could not be seen. I made, therefore, a firm pellet of cotton-wool on the curved forceps, saturated the pellet with the solution of the ethylate, and then plunged the pellet into the polypoid growth and retained it there for three minutes. The removal of the pellet was followed by violent sneezing, and a copious discharge of thick mucus and some blood; but when the discharge had ceased the nasal passage was found to be quite clear, and a curved director could be passed into the posterior nares without the least difficulty. The proceeding was followed by some pain and irritation of the mucous surface, which lasted for three days, but did not oblige the patient to keep to the house. On his return to me four days later the passage was so clear that I thought the cure was complete. This view was not confirmed, for a few weeks later the obstruction recurred, and the patient was once more brought to me, by my friend, with a polypus as large as before, and completely obstructing the passage. The same plan of treatment was repeated and with the same result of completely destroying, for the time, the polypoid mass. The irritation again continued for two or three days, after which I was enabled, by the speculum, to see the point from which the growth took its attachment. I now directed, with the curved forceps, a pellet saturated with the ethylate on to that spot, and repeated the application every five or six days. Some ulceration followed the last application, but the ulcer healed kindly and left the nasal passage quite clear. The latest report I received, eleven months later, was that the recovery remained complete.

On the whole, I think this case promises a very useful application of the ethylate in a new direction. On theoretical grounds cases of polypus are precisely those in which the ethylate should rapidly produce a destructive action, and in practice, as I have so far seen, the effect is in perfect confirmation of the theory. If further experience should be of the same character, a very troublesome affection will have become amenable to one of the simplest possible forms of curative treatment. Aural polypus will probably in like manner be successfully treated by the same method, and it may be that some varieties even of uterine polypus will, in skilful hands, be removed by the application.

The Ethylate in the Treatment of Ozœna.—The employment of sodium ethylate in the treatment of nasal polypus led me to think of using it in ozæna. Here I have had an experience in a long-standing but not extremely severe example of the disease. In this instance, in a young girl, the affection was confined to one nostril, from which there was constant fetid discharge, with evidence of ulceration of the mucous membrane at the distance of about an inch within the cavity. In this case I diluted the ethylate with absolute alcohol to one-half, and then introduced a pellet of cotton-wool, by means of the curved forceps, into the canal, up to the ulcerated surface. Withdrawing the forceps, I left the wool in the cavity for five minutes, and then withdrew it. The application was attended with severe pain, and was followed by an irritation which lasted for three or four days; but the secretion was so much arrested and the offensive odour so greatly relieved that the patient willingly permitted a repetition of the treatment for three successive times. The discharge thereupon entirely ceased, and the odour has not again been noticeable after a period of several months, so that I hope a cure has been effected.

In these cases, again, the theory of the action of the ethylate as a means of cure is quite in accord with the promise suggested by theory, and that, too, though the bony structure should be the seat of ulceration. For I find that the action of the ethylate on soft bone and cartilage is to destroy texture by the decomposition of water, and to fix or pectise the gelatinous matter. The ethylate may thus again be extended in application on this basis of operation. It may, I think, be often successfully used for the destruction of caries or necrosed bone, attended with purulent discharge.

The Ethylate in the Treatment of Lupus.—When I first began to study the action of the ethylates I entertained some hope that they would prove useful in the treatment of malignant growths, and of those pseudo-malignant ulcerations to which we give the name of lupus. So far I have neither been able to confirm nor give up these anticipations. For the destruction of fungoid growths of limited size in malignant ulceration sodium ethylate answers well, but I should be saying too much at present if I assigned for it anything more than a caustic action, rapid and effective, and antiseptic. In treatment of lupus non exedens the results, with some few fortunate exceptions, have been negative. My late esteemed and valued friend, Mr. Robert Ceely of Aylesbury, consulted me last year about the case of a lady who for many years had suffered from lupus non exedens of the face. The ulceration extended over the greater portion of the surface of one cheek, and had shown no tendency to heal until Mr. Ceely commenced the application of the ethylate of sodium. I saw the patient three times, and recommended that the ulcerated surface should first be lightly covered with cotton-wool, and that the cotton-wool should be then saturated with the solution. The application was made every fourth or fifth day; a scale or crust formed, and at the last visit of the patient to me a most decided improvement had occurred. The ulcerated surface had greatly contracted, and the part that had not contracted was covered with a dry scale. In his last letter to me Mr. Ceely reported that the improvement continued, and that he expected there would be complete healing. I am sorry that I have not heard of the further progress of this case.

I have had under my care for nearly eight months a case of lupus exedens, affecting the face on the left side and involving the left ear, in which the treatment with the ethylate has yielded the following results. When this gentleman first came under my care there was a large fungoid vascular growth beneath the ear, which seemed to be increasing rapidly in size; while from the surrounding ulcerated surface there was a free acrid discharge, which was exceedingly fetid—so fetid, in fact, that the odour was detectable at a distance from the sufferer. There had also been several severe attacks of hæmorrhage from the vascular growth. In this case I treated the vascular growth freely with the ethylate, using it diluted to one-half with absolute alcohol. Some hæmorrhage followed, but was arrested at once by the use of the styptic spray which I brought into practice in 1866, and which consists of a mixture of absolute alcohol and pure ethylic ether, in equal parts, saturated with tannin. A firm crust was produced by the ethylate, and the growth was entirely removed. Since then the ulcerated surface has been treated with the alcoholic tannin spray, and whenever there has been a reappearance of vascular growth the ethylate has been again successfully resorted to. At one time, after the use of the ethylate, so good a cicatrisation commenced, that I ventured to treat all the ulcerated surface with the ethylate by using a diluted solution of it in alcohol, one part in ten, in the form of spray. Under this, used every third day for five weeks, there seemed to be a general indication of healing. A thin dry crust formed over the surface, and there was general contraction of the ulcer. Unfortunately these good results were not maintained. Some affection of the general health of the patient during the damp cold weather led to enervation and general debility, during which the ulcerative process became active again, and the parts which had contracted and healed recommenced to discharge. Recently, without alteration in the plan of treatment, there has been once more an improvement; and, on the whole, in the eight months there has at least been an arrest of the disease. That there is death of nervous supply further back I have no doubt, inasmuch as there is trifacial failure; and that in the end the ulcerative mischief will extend I have every reason to fear. I do not therefore suppose that the mere local treatment is more than palliative. At the same time, as a local measure, it is by far the best of any I have ever seen. It prevents decomposition; it destroys vascular growth; it restrains purulent discharge. It has not caused a basic curative effect, but it has limited local extension of disease, has made existence much more endurable, and has, I believe, prolonged existence considerably.

Subcutaneous Injection of the Ethylate.—The question whether the solution of sodium or potassium ethylates may be used by subcutaneous injection for the destruction of abnormal growths deserves to be tested. In my earliest communication I suggested their employment for this purpose, and Dr. Sedgwick has reminded me that in a case in which he and I were once in attendance we did, as a last resource, use the ethylate of sodium in the manner referred to. This case was one of extreme hypertrophy of the thyroid gland. The patient was a lady of about fifty-six years of age. She had suffered from enlargement of the gland for many years, and various plans had been adopted for removal of the gland or for reduction of its size. A short time before she came under our care the tumour had been pierced by the needle, and the electric cautery had been brought into requisition several times. At the last of these attempts the needle had broken, and from three to four inches of it remained permanently in the gland. This was sometimes a cause of pain, but was quite supportable, and was probably no more than an occasional inconvenience. The serious part of the case was that the growth continued, that the skin was distended to the extremest degree, that the trachea was pushed far on one side, that the venous channels through the neck were obstructed, and that the œsophagus was so constricted from the pressure that nothing but fluid food could be swallowed, and even that with difficulty.

In this condition we endeavoured to remove the gland section by section by the subcutaneous destruction of it from injection of the ethylate. Selecting the part where pressure from within was most declared we injected thirty minims of the solution into the structure of the gland at the distance of about an inch from the surface. The operation was followed by some slight local heat and throbbing, which passed away in a few hours, after which there was a very distinct reduction of size and tension of the gland at the part injected. In a few days we injected again with similar good results, and after six injections the gland was reduced to at least a third of its size, with the greatest relief to the breathing and complete relief to the œsophagus. We were congratulating ourselves on our success when an accidental check succeeded. After coming to my house to have a further subcutaneous injection the patient, who insisted on walking home, was immersed suddenly in a dense London fog with rain. Losing her way for a time, she reached her home at last wet through, extremely exhausted and suffering from cold. She was in this way subjected to an acute attack of bronchitis, with severe cough and expectoration, in the course of which the thyroid became congested and inflamed. Abscess formed in the gland, followed by free discharge of pus. In spite of all she, nevertheless, began to recover and to get up and attend for some weeks to a part of her daily duties, but with an impression fixed on her mind that she should die, and a constant expression that she wished to die. One evening, after making preparation for Christmas festivities, she summoned all the servants under her control, gave some of them presents, expressed regret that she had chided one of them, and then bade them all good-by and dismissed them from her room. A little later a loud ringing brought them back, to find her on the floor with the wound in the neck open and bleeding freely. Dr. Sedgwick was quickly in attendance, and found that she was dead from the loss of blood from one of the large veins involved in the gland. Whether bleeding from the wound alarmed her and led her to remove the dressings, or whether she ruptured the vein herself by interfering with the dressings, we could not tell, but the accidental mode of termination does not to my mind affect the treatment at all in regard to principle; and should another instance of enlarged thyroid come before me in which death from pressure on the œsophagus is inevitable, I shall not for a moment hesitate to suggest the same mode of destroying the gland in sections by the subcutaneous injection of the ethylate.

There are some minor uses for the ethylate, which are not without their practical value. I have used it successfully for removing warts, for destroying a small melanotic growth on the face, for a ringworm which had long withstood other forms of local treatment, for the removal of a small loose hæmorrhoid, and for the destruction of the vascular growth dependent on an ingrowing nail. In fact, the ethylate becomes after a little practice with it like a kind of supplementary knife, and in many cases takes the place of the knife without suggesting the fears that are so often connected with that useful but dreaded instrument.

One or two words as to the mode of application. In my first paper I recommended the exclusive use of a glass rod for applying the solution. As I have become more familiar with the treatment I have more commonly used a brush of camel's hair, as more readily applicable. The only objection to the brush is that one using of it destroys it—a trifling objection. Occasionally, when I wish to put on the solution in fine points or lines, I employ a new quill pen, taking the solution up with it in the same way as ink would be taken if the pen were about to be applied for its usual purpose. In this manner the fluid can be applied drop by drop or in line to the part, and its action can be confined precisely to the spot required.

When the solution is used in the form of spray, it should be diluted with absolute alcohol, sp. gr. 795, and sprayed through a Seigle's disperser. The operator in using the spray must be careful not to inhale it himself. In spraying it one day, a little of the fine spray was reflected back into my face, and I inhaled a breath of it, the effect of which was to cause a soreness and irritation of the throat, which lasted some hours. This, however, need not cause alarm. A weak solution can be actually sprayed into the throat, and in cases of malignant sore-throat might prove of great service.

To relieve the pain that is connected with the application of the ethylate, an alcoholic solution of opium may be added with good effect, but for this purpose chloroform must never be used. Chloroform mixed with the ethylate may explode with some violence. All the alcohols treated with sodium or potassium yield a sodium or potassium substitute, and I have made an amylate, a butyrate, and other similar compounds. Whether they will prove useful in medicine remains to be seen. Again, whether potassium ethylate has any advantages over sodium ethylate remains also to be seen. I may relate of potassium ethylate that it is much keener in its action than its sodium ally. It is nearer to the knife, and might almost rival the knife when used in its concentrated form. I have no doubt it will one day come into extensive application, for the whole study of these pectising alcoholic caustics is but in its infancy. For my part, I am repaid already in having been the pioneer in the study, and whatever successes my more learned successors may achieve from it, I most heartily offer them welcome and good-will.

EPITOME OF A PAPER ON THE NATURE AND RELATIONS OF THE DISEASES OF THE EAR.

By ROBERT SINCLAIR, M.D.,
PHYSICIAN AND AURAL PHYSICIAN TO THE DUNDEE ROYAL INFIRMARY.

(Concluded from p. 208.)

THE symptoms common to all acute inflammations are familiarly known by the description of Celsus, "*rubor et tumor, cum calore et dolore.*" The symptoms which, in addition to these, more specially characterise the disease under consideration, are impairment of hearing, giddiness, a sense of fulness in the head, and increase of pain on mastication, swallowing, moving the head, and blowing the nose. If the ear be inspected in the earliest stage of the attack by means of a speculum and a mirror of 5″ or 6″ focal distance, signs of vascular injection will be seen in the part first affected, which will be the dermoid layer of the membrana tympani, if the disease has originated in the external meatus, and the lining membrane of the tympanum and the mucous layer of the membrana tympani if it has taken its origin from the usual source, the pharynx. Should the attack be a very slight one or be appropriately treated at first, resolution occurs, and in a short time the illness terminates without leaving any evil results behind. But if left to itself in the milder cases effusion of mucus occurs, and in the more severe suppuration. These processes usually occur within forty-eight hours of inception, a fact which gives us a very significant hint for early and rational treatment. During this stage there is usually bulging of the drum-head, observable on inspection, and all the local and general symptoms become much more severe. It is even yet possible for the patient to be relieved without surgical aid by the escape of the effusion down the Eustachian tube. But as this channel is usually swollen and blocked up, such a happy result is exceedingly rare. The more usual course for the effusion to follow is the one we would naturally expect—namely, the direction of the point of least resistance—the membrana tympani, and the patient is fortunate indeed if rupture occur before serious disorganisation of the organ takes place. But his troubles are by no means at an end if his medical adviser is sceptical of the propriety of meddling with such a "useful safety valve" as a "trifling discharge from the ear." He has before him the possibilities of a life-long disgusting suppuration and irremediable deafness. If he be a child who has not learned, or has only recently acquired articulate speech, deaf-mutism is almost a certainty. And in any case he may at any moment fall a victim to meningitis, cerebral abscess, or pyæmia.

To say that the only foundation for the rational and successful treatment of this disease is to be found in the general principles which guide us in the treatment of inflammation is, I am aware, to utter a most obvious truism. But it is, nevertheless, a truism which has too largely shared the neglect proverbially attached to things familiar.

In the first place, we must, as far as possible, remove the cause, and prevent the operation of other possible causes. These objects we attain by attending to the external meatus and the pharynx, and in children by lancing swollen gums.

Secondly, we must procure absolute rest for the organ, and, as far as possible, physiological repose for the body generally. With this aim we place the patient in bed, in a well-ventilated and otherwise comfortable apartment; procure for him the greatest possible quietness by diminishing talking and noises to a minimum, and by placing a pledget of absorbent cotton wadding in the ear; and permit no food requiring mastication, for mastication obviously interferes with rest of the organ.

Thirdly, we must moderate the local action by general and local measures. To accomplish this end we must, in the first place, attend to the state of the excretory organs. A judicious selection of vascular sedatives and narcotics—such as aconite, tartar emetic, opium, and chloral—must be made, according to the requirements of each case. And, above all, there should be no hesitation in adopting the aid of our trusty ally, bloodletting by means of leeches. As the situation selected for this measure is a matter of prime importance, I shall ask your attention for a moment to the vascular supply of the organ. The posterior auricular, the anterior auricular branches of the temporal, and the deep auricular branch of the internal maxillary are the arteries of the external meatus. The last-named vessel is the source of the principal arterial supply of the membrana tympani. The stylo-mastoid branch of the posterior auricular reaches the tympanum through the aqueduct of Fallopius, and the tympanic branch of the internal maxillary enters by the fissure of Glasser. These are the two chief arteries of the tympanum.

From these facts it would appear that leeches should be applied in front of and below the external meatus, and certainly not over the mastoid, unless there is evidence that the mastoid cells are also implicated, in which case the parts both before and behind the meatus should be bled. In a child two or three, and in the adult not less than six, leeches should be applied. The meatus should be carefully plugged with wadding before the operation, to prevent the leeches and blood entering it. After the operation the bites should be carefully covered with plaster, to prevent their inoculation with pus, and fomentations by sponges wrung out of hot water, or, what is better, by warm water syringing of the meatus, should be sedulously adopted. "Never poultice an eye or an ear" is an injunction that cannot be too often repeated, for in neither organ can we afford to run the risk of suppuration and its consequences.

Lastly, if the products of inflammation have accumulated, it becomes our business to procure for them a safe and speedy exit by means of the knife. For the performance of this operation we require good light, a wide speculum, a concave mirror of 5" or 6" focal distance, attached by a band to the forehead, and a delicate, sharp-pointed knife. Many instruments have been devised for making the incision. But the one which seems to me to fulfil all the requirements in the highest degree is the myringotome by Dr. Woakes. This beautiful instrument has the supreme merit of perfect safety. It is a sharp-pointed, double-bladed knife, concealed in a cannula, worked by pressure on a spring, and fixed in an angularly-placed handle. In accordance with a well-known principle of surgery, a free incision should be made at the bulging point, if one can be clearly detected; and if not, in the lower segment of the membrane, behind or in front of the handle of the malleus. A good deal can be said for both positions. After the fluid has been evacuated, the inflamed surface should be washed every few hours by copious injections of water about the temperature of the blood, with the double view of diminishing inflammatory action and removing its products. The best way to do this is by means of a brass syringe, fitted with a somewhat conical-shaped nozzle to fit into the meatus, and ensure the thorough washing of the meatus, tympanic cavity, and Eustachian tube. To use a small glass or pewter syringe is merely to trifle with a serious inflammation and the fate of an important organ. A well-made Higginson's or india-rubber ball syringe fitted with a proper nozzle is, however, a good substitute for the brass syringe. In the intervals of syringing the patient should lie on the affected side to permit the free escape of discharge; and a piece of absorbent wadding should be loosely placed in the meatus to soak up discharge and protect the ear from the injurious effects of cold and noise. From the time of the natural or artificial opening of the abscess, the Eustachian tube should be kept pervious—in the adult by the daily gentle use of Politzer's inflator, and in the child by the simple expedient of blowing air up the closed nostril through a piece of india-rubber tubing. In a few days, when inflammation has somewhat abated, weak, warm, astringent solutions should be injected twice daily after cleansing with warm water. Solutions of sulphate of zinc or copper and the sulpho-carbolate of zinc are those which I have found most satisfactory. Vegetable infusions, on account of their liability to decomposition, should on no account be used. It is hardly necessary to say that after every wet application to the ear the meatus should be carefully dried by turning the head on its side, so as to allow the fluid to trickle out, and by using a piece of soft rag.

The line of treatment which I have rapidly sketched may at first sight appear elaborate and difficult of execution. But a moment's reflection will convince you that it is neither more nor less than the common-sense application of well-known principles of surgery; and speaking from my own experience I have invariably found both patients and their friends willing co-operators when the objects of the treatment and the probable consequences of neglect have been fairly placed before them.

If I am asked what measure of success is likely to attend the adoption of this plan, I can only answer, from my own experience and that of numerous others, that the results are quite as good as could be expected from the rational treatment of an acute abscess in such a situation. Quite recently I have had under my care two cases of acute suppuration of both middle ears in adults. In both cases perforation had occurred before I was consulted; and in both entire cessation of inflammatory action, perfect healing of the membranæ tympani, and complete restoration of hearing power were obtained within six weeks of the commencement of treatment.

If you admit, as I think everybody must, the truth of Sir William Wilde's observation, that "as long as discharge from the ear is present we can never know how, when, or where it may terminate, or to what it may lead," if you think of the immediate and future dangers of tympanic suppuration, if you concede its evident disqualification for life assurance, and if you reflect on the restraining power of imperfect hearing in the keen and eager struggle for existence, rank, and wealth,—you will not fail to recognise the importance of accurate diagnosis and rational treatment, and you will find in the study of the diseases of the tympanum a field for the exercise of your best skill, care, and talents, a source of gratification to yourselves, and of inestimable benefit to your patients.

Dundee.

THE annual meeting of the governors of the Birkenhead Borough Hospital was held at the Music Hall, on Jan. 31st, the Mayor (Wm. Laird, Esq.) presiding. The report of the committee of management stated that the total number of patients relieved during the year 1880 was 7724, of whom 535 were in-patients. The total expenditure amounted to £2138 11*s.* 3*d.*, being an increase of £130 1*s.* 9*d.* on the previous year. The total ordinary receipts for the year were £2331 9*s.* 6*d.*, an increase of £419 2*s.* 4*d.* on the previous year. The total receipts exceeded the disbursements by £192 18*s.* 3*d.* The committee most gratefully acknowledge the handsome donation of £250 received from J. T. Hickells, Esq., of Noctorum; and a legacy of £100 (less duty) from the late J. Crowther, Esq., of Oxton. Owing to the yearly increasing number of in-patients the committee considered that the opening of the fourth ward had become a matter of pressing necessity. This, however, could not be done without adding a wing to the main building and making some other slight alterations, at a probable cost of not less than £600.

THREE CASES OF KNEE-JOINT ABSCESS IN CHILDREN.[1]

BY EDMUND OWEN, F.R.C.S.,
SENIOR ASSISTANT-SURGEON TO ST. MARY'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN.

THE three patients whom I have the honour of showing this evening are not selected; they happen to have been lately under treatment together, and are, indeed, the only instances in which I have recently had occasion to open the knee-joint for suppurative arthritis. Short as the series is, these cases offer, I think, an interesting subject for discussion and criticism; and especially so as you have just had the opportunity of examining the present condition of the joint in each instance. The eldest child only was treated by me as an in-patient; the others were brought as out-patients to the Children's Hospital.

Briefly, the line of treatment has consisted in free incisions into the joint and subsequent free drainage; in absolute and prolonged rest of the limb with compression of the articulation; in constitutional and dietetic support, and (need I say it?) in local cleanliness. But having remarked that I have employed cleanliness in the treatment of these diseased and opened joints, the conclusion that I adopted the high ritual of spray and the vestments of gauze would be both hasty and inconsequent. I wish it, however, to be thoroughly understood that I did my best to keep the articulations clean, both on the exterior and in the interior. I would like it to be understood also that by no means do I bear the spray and gauze ill-will; I even look upon them as a kind of safety-lamp which may well be carried by those who work in an atmosphere of surgical fire-damp, as well as by those who, trespassing in the seductive regions of speculative surgery, may on occasion require evidence of their having started on their excursion without neglect of approved precaution To the great champion of cleanliness in our art I personally owe a boundless debt of gratitude, but to certain of his enthusiastic disciples who, to speak within bounds, seem to consider those who do not adopt their creed as wilfully obstinate or morally oblique, I will delicately put this question, Could any other method of treatment have obtained better results than those which we have now before us?

Our medical journals are continually called upon to publish reports of cases, trifling and serious, which have recovered after "antiseptic treatment," that this short series out of the groove cannot now but be of interest. Possibly even they may help to show that *post* and *propter* when employed in connexion with a certain surgical practice need not be confused even when half-obscured in a cloud of carbolised vapour.

The first case is that of a girl of about four years of age. A little more than two years ago she was brought into the out-patient room in Great Ormond-street in a most pitiable condition. The left knee was red and enlarged from a collection of fluid in the interior. So painful had the joint been that appetite and sleep had left her. Moreover, she had had several attacks of convulsions—the rigors of childhood. Ten months previously, the mother said, the child had fallen off her chair, and directly afterwards the knee had begun to swell; but though the swelling had steadily increased, the child had been able to limp about until three weeks ago. The whole limb was red and swollen. She was at once put to bed, and the Registrar (Dr. Abercrombie) going round next morning noted that the leg and thigh were the seat of erysipelas, and that there were several blebs on the leg. The glands in the groin were enlarged and tender. Though there was a small sinus leading towards, or into the joint, from the inner side, from which a thin fluid was oozing, the patella was floated from off the femoral condyles. The temperature was just under 101° Fahr. On the third day after her admission—that was when I next saw her—chloroform was administered, and a free incision was made on each side of the knee, much thin pus escaping. The finger passed into the interior of the joint detected much thickened and pulpy synovial membrane, but no diseased bone. The joint having been thoroughly washed out with a weak solution of chloride of zinc a drainage-tube was passed through it, and the limb was put up again on a slightly bent tin splint. Nevertheless, the erysipelas continued to advance, and blebs now had made their appearance on the thigh, and the temperature went up two or three degrees. The child was taking quinine, iron, and wine; in less than a week the temperature began to track the chart along the normal line. For convenience in the washings, which were daily performed by the house-surgeon, Mr. Kempe, the back splint was changed for extension by the stirrup, weight, and pulley. A month after her admission the joint was strapped, the drainage-tube still lying in the outer wound; and at the end of another like period she was taken home in excellent condition, the wound, though steadily closing, still weeping a little. But at home she did not prosper, and in three weeks she was again in hospital for ten days. Since that time she has steadily improved, the limb being fixed upon a back tin splint. It is no exaggeration to say that in function and movement the damaged knee is now as good as the other. The child runs about on it all the week, and kneels upon it on Sundays. It is absolutely free of pain.

The second case is that of a little boy. The mother says that the disease was started by a fall out of bed upon the knees, after which the right joint began to swell. At the beginning of last year he was sent to me by Dr. Goullet, of St. John's-wood, for an attack of subacute synovitis. The child was then under a year and a half old. We fixed the limb on a tin splint, and Dr. Goullet looked after the child until April, when, in spite of the treatment adopted, the inflammation had run on to suppuration. In this case only one incision was made into the joint, and that on the inner side. The solution used for washing was weak tincture of iodine. Three days after that operation it was noted that the child had lost its thirst and that its nights were quiet. Previously it had been in the habit of starting in its sleep and awaking with a scream. Seven months later it was remarked at the side of the prescription-paper, under the date of Nov. 17th:—"Has been wearing the splint up to to-day. The wound has healed, but there is a good deal of eczema around its site. There is good flexion and power of movement in the joint, but there is still some fulness about the ligament of the patella from the old thickening of the synovial membrane. The health is excellent." There is no tenderness at the knee, which can be bent, without disturbing the child, to less than a right angle. Though the skin over the old wound is not sound-looking it is serviceable enough, and the child cruises about the room without inconvenience.

The last case is that of a baby of four months, who was brought as an out-patient from Hendon at the end of last June. Against his name in the case-book I then wrote: "Subacute synovitis of the left knee-joint," and fixed the limb on a bent splint with strapping and soft bandage. But by the tenth day it was evident that a purulent collection occupied the synovial pouch. Excessive pain in the part had driven away sleep, and the child had attacks of convulsions. The knee was red, hot, swollen, and very tender. By means of incisions, and injections of weak tincture of iodine and water, much thin sero-purulent fluid and flakes of thick and curded pus were washed out of the joint, and the limb was then packed round with vaseline lint and tenax, and fixed to a splint. Gradually the splint was straightened, and by the middle of September drainage was discontinued, and the wounds healed up. The child never had a bad symptom. In October last there was free movement in the joint, and the infant was flourishing; and, as you have seen to-night, the child allows full examination of the capabilities of the joint to be made. He even flexes it of his own accord; and, his mother says, tries to walk on it.

I am well aware that there is nothing of an extraordinary nature in these reports and cases, unless it be the simplicity of the treatment adopted. A treatment somewhat similar to that described by Mr. Sampson Gamgee,[2] with this exception—improvement, I will call it—that the pus is straightway washed out of the joint, instead of being allowed to ooze out. So the joint gets a well-considered and fair start towards the goal of recovery.

In conclusion, I will venture to express the opinion that the chief requisites for obtaining such happy results in the treatment of acute joint-abscess in childhood are the early employment of clean and free drainage and the prolonged continuance of absolute rest. And these are conditions which are fortunately very generally obtainable.

Seymour-street, W.

ON THE NATURE AND SEQUENCE OF THE CARDIAC AND VASCULAR CHANGES IN INTERSTITIAL NEPHRITIS.

BY BRYAN C. WALLER, M.D., F.R.C.S. EDIN.,
LECTURER ON PATHOLOGY IN THE SCHOOL OF MEDICINE, EDINBURGH.

(Concluded from page 209.)

THE obliterative changes in the intima appear to consist essentially in a proliferation, and subsequent fibrous transformation of the connective-tissue structures of the inner coat. The proliferation is probably due to irritation caused by the circulation of some blood-poison, such as those generated by gout, rheumatism, syphilis, chronic alcoholism, lead-poisoning, and chronic dyspepsia. I am thus inclined to refer the changes in the stroma and in the arteries to a common cause, and to consider that their development generally goes hand in hand, though those in the stroma are usually more marked in the earlier stages, as might be expected from the plentiful migration of leucocytes into the stroma, and from the higher differentiation, and consequently greater permanency, of the elements concerned in the formation of the arterial coats. There is, however, no fixed relation between the character and extent of the changes in the kidney stroma and those in the coats of the renal or systemic vessels—a fact which further corroborates the idea that they are dependent on a common cause, and refutes the supposition that the vascular lesions are originated by those of the kidney, or *vice versâ*.

The remarks which I have made relative to the state of the renal arteries hold good also broadly with regard to that of the arterial system in general. Substantially the same changes may be observed in the vessels of the pia mater, spleen, liver, subcutaneous tissue, &c., though generally to a less degree than in those of the kidneys. The adventitia is not, as a rule, thickened, though in two cases there was thickening of the outer coat of the arteries of the pia mater. This small percentage does not warrant any inference as to the connexion of the thickening with the state of the kidneys. In point of fact, the adventitia of the arteries of the pia mater is often thickened in cases quite unconnected with Bright's disease.[1]

Out of the twenty-six cases in which the heart was examined, there was hypertrophy unconnected with valvular disease in eighteen. The general rule seems to be that the more marked the obliterative changes in the intima of the arterioles the greater the degree of cardiac hypertrophy. In my cases I have been struck with the distinct relation which the one seemed to bear to the other. The number of cases is, of course, too small to justify definite conclusions, though provisionally I am led to adopt the opinion that the cardiac hypertrophy is secondary, and simply due to circulatory obstruction in the kidneys themselves and in the systemic vessels. In three cases where the kidneys were very granular, the intima of the arterioles much thickened, and the heart not hypertrophied, I attribute this fact to the general state of malnutrition which had subsisted before death. Under such circumstances I should not have been surprised had the heart been actually atrophied.

Besides those changes which I have already described in the arteries of the kidney stroma, there are others in connexion with the Malpighian bodies to which I must now shortly direct attention. These changes are principally, if not entirely, due to compression, by the fibrillar transformation and contraction of the nephritic cell-infiltration of the intertubular stroma. By this contraction the capillary loops of the glomeruli are emptied of blood and compressed; and being thus rendered functionally useless, they either undergo simple atrophy and become impervious, or are affected by colloid degeneration and converted into homogeneous or slightly granular masses, which under a power of 300 diameters appear very much like lumps of pretty firmly set gelatine. The colloid change is a very frequent one. In consequence of the obliteration of the glomeruli the blood in the afferent arterioles is prevented from traversing the capillary loops and so entering the efferent venules. A certain amount of rise in the blood-pressure must thus follow, which will not only act directly as one factor in determining an albuminous state of the urine, but will further contribute its quota towards establishing cardiac hypertrophy.

Three principal factors serve to determine a rise in the blood-pressure during the stage of cell transformation and shrinking of the kidney. These are:—Firstly, destruction of the capillaries of the intertubular stroma from contraction of the newly formed cicatricial elements. Secondly and chiefly, changes in the vessels themselves, both in the kidney substance and throughout the system generally, which lead to thickening of the walls with diminution of calibre, and roughening of the sides of the lumen; and, thirdly, destruction of the glomeruli, either by simple atrophy, by colloid degeneration, or by cystic dilatation.

The blood-pressure having been thus heightened, attempts at compensation are likewise initiated. Firstly, the walls of those renal vessels whose coats have undergone least alteration become abnormally permeable, and thus permit the transudation of albuminous substances. Secondly, according to Thoma, when a glomerulus has been destroyed, a direct communication is formed between its afferent arteriole and its efferent venule. Thirdly, anastomoses may form between the vessels of the capsule of the kidney and the small twigs of the supra-renal, phrenic, and lumbar vessels. Thus a portion of the blood which naturally passes through the kidney will be diverted, avoiding, as it were, the locked floodgates. These compensatory provisions are, however, insufficient, and the blood-pressure accordingly becomes permanently heightened. The heart, thereupon, begins to hypertrophy, in order to overcome the conditions obstructing the circulation—that is to say, if the general nutritional conditions are favourable. When hypertrophy is once established the heart is enabled, in great measure, to overcome the obstacles; but at the same time the augmented *vis à tergo*, acting in concert with the increased permeability of the walls of the renal vessels, serves to produce an aggravation of the albuminuric symptoms. These ideas are in accordance with the results of clinical observation, from which we learn that albumen is usually present in the urine in small quantities only during the first stage of interstitial change—namely, that of cell-infiltration; while in the second stage of cell-transformation and contraction it becomes more abundant, though it is seldom very copious in this variety of Bright's disease.

To me the most puzzling fact in connexion with the vascular changes is the hypertrophy of the middle coat. I cannot quite adopt Dr. Johnson's explanation, which ascribes it to the antagonism of the heart and arteries, the one, as it were, insisting on supplying and the other on rejecting the poisoned blood, so that both, like contending athletes, become presently strengthened by the prolonged struggle. Meanwhile I have no feasible exegesis of my own to proffer, unless it be that the hypertrophy of the middle coat is due to the same causes as that of the intima—a view not destitute of serious difficulties, considering the apparently true character of the muscular increase. The fact of the muscular hypertrophy is thus an inconvenient one, so far as regards the sufficiency of present explanations; but that fact it is, I am well persuaded.

The conclusions to which my series of cases appears to point are therefore shortly as follows:—

1. Certain changes in the vascular system are found in connexion with chronic interstitial Bright's disease.
2. These changes consist principally in thickening of the middle and inner coats.
3. In the case of the systemic arteries, the outer coat does not undergo any change which can be connected with the state of the kidneys, though in the kidneys themselves it is sometimes secondarily blended with the surrounding increased perivascular connective tissue.
4. The hypertrophy of the heart is compensatory, and secondary to obstructive causes. It seems to bear a definite relation to the degree of obliterative thickening in the tunica intima of the systemic arterioles. There will, however, be no hypertrophy if the general nutritive conditions of the system are markedly bad.
5. The changes in the arterial coats are, in all likelihood, due to the same primary cause as the alterations in the kidney stroma—namely, the circulation of poisoned blood; though the affection of the vessels is generally subsequent in point of time, owing to the more differentiated, and therefore more stable, nature of the vascular tissues, and the non-occurrence of cell emigration into the arterial tunics as into the kidney stroma.

---

[1] See Dr. Grainger Stewart, Brit. Med. Journ., Nov. 15th, 1873.

6. Interstitial changes may occur in the kidney apart from any alterations in the arteries, if the renal disease prove fatal before the latter have time to develop. This is seen in cases of glomerulo-nephritis, where death generally occurs rapidly, with symptoms of suppression of urine, uræmia, and acute dropsy.

7. The general order of sequence of the various items in the morbid process appears to be: (*a*) blood-poisoning, (*b*) renal changes, (*c*) vascular changes, (*d*) cardiac hypertrophy.

Edinburgh.

PENETRATING GUNSHOT WOUND OF THE SKULL; LODGMENT OF BULLET IN THE INTERIOR OF CRANIUM; RECOVERY.

BY J. KINGSTON BARTON, L.R.C.P. LOND.

THE notes of the following, although very incomplete as regards the whole history of the patient (necessarily so from a cause beyond my control), yet, I trust, are sufficiently interesting to warrant their being placed before the profession.

A young man, aged twenty-two, received a penetrating wound of the skull from a bullet weighing thirty-four grains, discharged by a small Remington pistol. The wound was at a point about two inches above a horizontal line drawn across the eyebrows, and about a third of an inch to the left of the median vertical line of the frontal bone. About eleven hours after its infliction the wound gave the appearance of being merely a slight puncture of the scalp, there being little swelling, bruising, or discoloration at its site, though the left eye was closed by ecchymosis of the lids. On the third day the scalp began to swell under the wound. On the fourth day after the receipt of injury the scalp swelled in a globular form about three-quarters of an inch in diameter, the swelling pulsating synchronously with the pulse at the wrist. This pulsating tumour gave the feeling of there being fluid immediately beneath the skin, and the heaving did not seem to be expansile in its character. On the sixth day the swelling diminished, but instead of feeling a tense fluid tumour the fingers detected an apparently small circular depression in the frontal bone. On this day (sixth) Mr. Thomas Smith saw the patient in consultation with me, and having removed the scab a probe was passed into the wound.

The probe passed by its own weight into the cranial cavity in a line directly back towards the occiput, and was only restrained in travelling further by the fingers holding the end of the probe. About a teaspoonful of cerebro-spinal fluid escaped when the probe was passed, and after its removal the depression of the bone was more easily felt. The pulse was 44 before the probe was used, but it rose to 50 immediately afterwards. The cerebral symptoms had been those of compression during the few days previous to the exploration with the probe. A piece of lint soaked in carbolic oil was applied to the wound, and was not removed until the wound had healed. Some other pieces to keep the first in place were renewed daily, but a little carbolic oil daily poured over the original piece of lint was the only local treatment used. The skin wound was quite healed on the fourteenth day after the injury. The symptoms of compression, which were existent from the first day, became most marked on the fifth day, but within twenty days the pulse had risen to 60, and no cerebral symptoms of importance remained. The temperature from the first was never above 99° F. The pupils were contracted. The patient for a long time complained of pain at the injured spot, as also at the occiput. When seen at first, about eleven hours after the injury, the left eyelids were extensively ecchymosed, so much so that three days elapsed before the ophthalmoscope could be used. The optic nerve was then found to be swollen, and in the condition called ischæmia. The optic disc in the right eye was normal. It is difficult to say for certain whether this ecchymosis and ischæmia arose from an injury to the cavernous sinus preventing the return of blood by the ophthalmic vein on the left side, or was merely a consequence of a blow upon the eye. Within four weeks the disc had cleared up considerably, leaving distinct signs of its previous condition; but no atrophy occurring, as was evident by the vision of the eye being equal to that of the right eye (which vision was normal), the probable cause of the ischæmia was an injury to the eye, producing not only ecchymosis of the lids, but also extravasation of blood in the neighbourhood of the optic canal, thus causing pressure on the veins of the optic nerve, and giving rise to the condition observed with the ophthalmoscope. The senses of taste and smell seemed to be quite lost after the accident. The patient was always a subject of thick nasal and pharyngeal mucous membranes, together with a tendency to enlarged and inflamed tonsils, so that his sense of smell was probably never very acute. The loss of taste would be partially dependent on the loss of smell, but the glosso-pharyngeal or facial nerve may have been injured near their roots. The loss of taste seemed to be general, as no localised areas unaffected could be discovered. He had double vision for some days, but being very slight, it was difficult, owing to his confused mental state, to determine whether it was due to a temporary paralysis of the external or internal rectus of his left eye. However, the external rectus seemed to be the muscle at fault. The anomaly did not last long.

There are many other points of clinical interest which might be mentioned, but as the case cannot be published in its completeness now, my chief object is to relate the points that bear on the advisability of treating gunshot wounds of the skull by leaving them alone, if possible, rather than surgically interfering with them. The patient convalesced most favourably until forty days after the injury, when suddenly one evening he was seized with most violent pain at the point of injury, accompanied by several rigors. The pulse soon rose to 100, and the temperature to 103° F. He was almost unconscious, and wildly delirious. Within a few hours he was very sick, bringing up a great quantity of undigested food. The pain, delirium, and fever continued for several days, and then gradually subsided. At the time of this sudden attack there was a partial facial paralysis, or, perhaps more correctly, a paresis of the right side of the face. There was no optic neuritis of the right eye, nor were there any fresh signs of it in the left eye. During this attack he was treated with small doses of calomel and opium for a few days, and it seemed to relieve the bowels and head. Appropriate local remedies were applied to the head. Excepting an effervescing mixture of soda whilst he had the feverish symptoms, he had little or no other medicine. From the time of injury until his critical attack as related above, his bowels had to be relieved daily by enema. The small doses of calomel were sufficient to produce evacuations without the aid of an enema, absolute quiet and the blandest food being the chief treatment relied on. He gradually recovered strength from this time, his appetite, owing to the partial return of his taste, coming back to him, and he was able to go into the country on the seventy-fourth day after the accident for change of air. He is still perfectly well in all respects, five months having elapsed since the accident.

General remarks.—Penetrating wounds of the skull produced by firearms are necessarily of a very grave nature, but this case is a good example of treating such injuries in the simplest manner. In military records there are a good many examples of recovery after a bullet has been lodged in the cranial cavity. The local treatment in this case consisted in providing a free escape for any fluid that might collect in the track of the wound, so as to avoid intracranial pressure; at the same time that the wound was shielded from the contact of air by a veil of lint soaked in carbolic oil, no attempt being made either to search for or remove the bullet. A similar plan was adopted with equal success in a case recorded in THE LANCET, May 3rd, 1879, by Mr. Smith, where the skull and brain were shot clean through from side to side, and where the bullet was felt beneath the scalp, near its orifice of exit from the skull. It is more than possible that operative interference with a view to remove the bullet in such cases does more harm than good; and illustrative of this may be mentioned a case recently recorded in THE LANCET, Oct. 2nd and 9th, 1880, by Mr. Gamgee, where the removal of a bullet lodged in the petrous portion of the temporal bone seemed to inaugurate a train of symptoms which shortly proved fatal.

Gloucester-road, S.W.

THE Governors of the Sussex Eye Infirmary have resolved to rebuild the institution, to meet the growing requirements of Brighton and the county.

KING'S COLLEGE HOSPITAL.

TWO CASES OF OBSCURE ABDOMINAL TUMOUR; OPERATION; CURE.

(Under the care of Mr. JOHN WOOD.)

CASE 1. *Fibroma of cæcum; removal; recovery.*—E. C——, aged twenty, a healthy-looking lad, subject to frequent attacks of constipation, with large and evident intestinal accumulations, was originally admitted into a medical ward. These attacks commenced by some slight typhlitis, followed by a rise in temperature. They were relieved by restricting the diet to milk, and by giving large doses of castor oil every night and enemata. Whenever the bowels were relieved a hard pyriform mass could always be felt behind and below the cæcum, and evidently either growing from it or the ilium.

The patient was after a time transferred to the surgical care of Mr. Wood. At this time a resonant note could be percussed out over the cæcum. Behind this and below it was a hard pyriform non-movable tumour. There was no pain on pressure; the legs did not swell, and there were no enlarged glands in groin, nor was there a history of syphilis. The kidneys, heart, and lungs were apparently healthy.

On June 5th the patient was placed under the influence of ether, and a semilunar incision, six inches in length, was made parallel to Poupart's ligament. The superficial epigastric was cut and tied; the external oblique fascia, the internal oblique, and the transversalis muscles were cut through at right angles to their fibres. Troublesome hæmorrhage occurred. The transversalis fascia was much thickened and indurated, and was divided on a director. The deep circumflex iliac artery was cut, and tied with difficulty. On cutting through the transversalis fascia the tumour was exposed. It was found to be of the size of three walnuts, adherent three-quarters round the cæcum and external to the peritoneum. It cut like scirrhus, and was very vascular. The tumour was dissected as close off the peritoneum as possible. A counter-opening was made anteriorly to the quadratus lumborum, a large drain-tube inserted, and the wound was united with three sets of sutures. The patient was then placed in hernia position. Strict antiseptic precautions were observed throughout. At 6 P.M. the temperature had sunk to 95·6°; pulse 102, intermittent and almost imperceptible. Patient was in intense pain. Champagne and soda-water were given, but rejected at once. Finally, enemata containing alcohol were given. Eighteen ounces of high-coloured urine were drawn off by catheter. Next morning at 10, temperature 98·4°, there was incessant vomiting of greenish mucus. Patient fed entirely by beef-tea and brandy enemata. The wound was dressed, and was perfectly united superficially; no sign of redness or tension visible. 6 P.M.: Red sanguineous discharge through dressing. Pulse 144; temperature 97·4°; feeling of prostration; anxious look; cold, clammy sweat. The dressings were removed, and free hæmorrhage was going on from the large drain-tube. Ice bags were applied all over the abdomen, and iced water enemata were injected every half hour. On the 7th vomiting and retching were incessant, causing intense pain at the site of the wound. The patient was still fed by enemata entirely. Everything was tried to alleviate it: hypodermic injections of morphia, drop doses of creasote, effervescing draughts of bismuth and hydrocyanic acid, and, finally, effervescing draughts with solution of strychnine; but all failed, the patient becoming very prostrate and weak. On the 8th vomiting had slightly diminished. Subcutaneous injections of morphia given three times daily allayed the pain, and by the following day the vomiting had almost ceased, and the patient took champagne and soda by mouth, with a little brandy and beef-tea jelly. On the 10th the wound was dressed, and fæcal discharge was seen at orifice of drain-tube, showing the bowel had burst. The wound was dressed with tow and carbolic lint. All the sutures were cut, and the wound was allowed to heal up from the bottom. From this time the progress was rapid, the only difficulty being to keep the wound open and to preserve the skin from bedsores. On the 25th a free motion was passed per anum. Owing to the closure of the hospital the patient was transferred to University College Hospital, under the care of Mr. Marshall. He returned to Mr. Wood's clinique early in October, and the wound was then quite healed up. He had a daily free motion, but found that if he took a purgative it caused violent pain round the wound.

CASE 2. *Enchondroma of the peritoneum.*—(For the notes of this case we are indebted to Mr. S. Farmer, house-surgeon). G. S——, a labourer, about sixty years of age, was admitted to the Albert ward on Nov. 1st, 1880. He had always enjoyed good health, and there was no history of tumour of any kind in the family. Twelve months before he noticed a small swelling about the size of a marble in the left iliac region; this was freely movable. It gradually increased in size up to the date of admission. He had been gaining flesh.

On admission a large nodulated mass could be felt in the left iliac region. The tumour was rounded in shape, and of the size of a very large orange, and was situated on a level with the crest of the ilium, and in close proximity to the anterior superior spine. The skin was freely movable over it, but the tumour itself was attached below. Pain was experienced down the thigh in the course of the external cutaneous nerve.

On the 20th a free incision, six inches long, was made over the tumour. A careful dissection brought the tumour into view. Attempts were made to separate it from the surrounding structures, but it was found adherent to the peritoneum. At this stage the intestines protruded during a fit of coughing, and were with great difficulty kept within the abdominal cavity. The great bulk of the tumour was then removed; a small and quite distinct tumour, about the size of a filbert, was also taken away. Only two vessels required ligature. The peritoneum was stitched together with catgut, and a large drain-tube put into the wound. Antiseptic precautions were observed throughout. He vomited once after the operation. A grain of opium was ordered to be given every four hours. Next day the wound was dressed. It had quite united by primary adhesion. A catheter was passed twice daily.

The patient progressed most favourably until Nov. 26th, when a fæcal odour was observed, and liquid fæces made their appearance. Antiseptics were of course stopped. The wound opened up; the temperature, which had gradually been rising since the 23rd, was 100·4°; it dropped down to normal immediately after rupture of the bowel. Free fæcal discharge took place daily until Dec. 15th, when he had free motions per anum; and when he was discharged at the end of the month there was only a slight serous discharge from the wound.

Remarks.—With regard to the first case, Mr. Wood stated that he was half inclined to give up the operation when he found the tumour presenting so much of a malignant character; but, on microscopical examination showing it to be only of a fibroid nature, he was of opinion that removing the greater part of the tumour would cause atrophy of the remainder. A feature of the first case was the incessant vomiting of a greenish mucus, in spite of food being given only by enemata, and the entire failure of all the usual therapeutic remedies. In both cases it will be observed the bowel burst in the first on the fifth, and in the second on the sixth day. Doubtless the intestine must have been weakened by the necessarily close dissection; moreover, in the first case the vomiting must have in a great measure contributed to this result.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

CASES OF TRAUMATIC TETANUS.

(Under the care of Mr. J. D. RANSFORD.)

CASE 1.—R. P——, aged sixty-one, was admitted on Sept. 29th. Fourteen days before admission his finger had been badly crushed, and had been amputated by a house-surgeon. On admission the wound looked sloughy, and he complained of not being able to open his mouth well, but had no pain. Temperature 99°, pulse 76.

Sept. 30th.—Temperature normal, pulse 72; mouth opened to the extent of half an inch. No pain, no risus, or spasm about the body. An enema of fifteen grains of chloral was given, and later in the day forty grains of compound jalap powder, which moved his bowels several times in the night and once on the following morning. On Oct. 1st temperature and pulse normal, stiffness of mouth greater; opening to the extent of a quarter of an inch. To have thirty grains of chloral every four hours in enema. On the 2nd trismus not diminished, pain in the back of neck, temperature 100°, pulse 98. On the 3rd pulse 116, temperature 99°; trismus increased, stiffness of neck greater; corners of mouth drawn down. Ordered forty grains of bromide of potassium every four hours, and forty grains of chloral as an enema every four hours. Evening: Pulse 128, very weak and compressible; frequently recurring spasms, followed by vomiting. Chloral omitted on account of the state of the pulse, and one drachm of bromide of potassium ordered every four hours. To have a bath of 100° F. for an hour. Three teaspoonfuls of Brand's beef essence every second hour were easily swallowed without exciting spasm. On the 4th swallowed the medicine about six times; he thinking that ice stopped the spasm, he asked for it. Temperature 101·3°. Twenty grains of chloral hydrate at once, and followed by twenty grains in three hours—if necessary subcutaneously. 11.30 P.M.: Twelve grains given subcutaneously, and repeated at 12.30. Spasms as frequent as before, though patient felt drowsy. 4.30 A.M.: Twelve grains repeated subcutaneously; spasm less frequent and less severe; patient very drowsy. Temperature, 2 A.M., 99°. On the 5th the injection of chloral was repeated at 8.30 and 12. Temperature 100, pulse very feeble and compressible. Ordered twelve grains of chloral hydrate, sixty grains of bromide of potassium, and twenty drops of tincture of digitalis every four hours as an enema. Pulse so feeble that after the first dose the chloral was omitted. No spasm after 10.30, but the patient died exhausted, Oct. 6th. Not more than half the above enema could be retained at one time, the rectum being very irritable.

Remarks.—The patient was a strong healthy-looking man, and the symptoms were so slight that some hopes of his recovery were entertained. Dr. Wm. Carter also saw the case from the commencement.

CASE 2.—M. L——, aged twenty-five, was admitted on Sept. 26th. He was a healthy young man, employed as a tramcar driver. While trying to whip some boys clinging to the car he slipped, and the car passed over his right leg. When admitted it was severely lacerated and bleeding fast, apparently from one of the tibial arteries. Esmarch's tube was at once put on by the house-surgeon, and within half an hour Mr. Ransford saw the patient and amputated at the seat of selection by lateral skin flaps and circular division of muscles. Hæmorrhage was rather free at the time and somewhat difficult to stop. The operation was done under the spray and dressed with the carbolic gauze. About two hours afterwards rather sharp capillary hæmorrhage took place, necessitating the taking down of the stump. This was done under a large carbolic spray from a steam spray-producer. No vessel was found, but rather general oozing, which mostly ceased on exposure and clearing out clots, and elevating the stump. The dressings were reapplied, and the house-surgeon was directed to give a subcutaneous injection of three grains of ergotine if there were any fresh signs of the hæmorrhage. This was done in about an hour, when some blood showed through the dressing, but did not increase after this. The next day (Sept. 27th) the temperature was 100° in the moring, and 101° in the evening; pulse 100, very compressible. The wound was dressed, and looked very well. After this the pulse and temperature remained nearly normal up to Oct. 3rd, when the temperature was 100·6°, and remained 99° or 100° up to Oct. 6th, the morning on which he died, when it reached 103°. The leg was dressed every other day, nothing but a little serum being on the dressings after the first day.

On October 3rd, the day on which his temperature rose to 100° F., he complained of his throat being sore. Pulse 74, compressible. Nothing was seen in his throat; no risus; no trismus. Appetite good, able to take full diet. Next day he had dinner and breakfast, and took them without complaint. The first sign of stiffness of the mouth was noticed in the morning at 1 A.M., and in the evening of the same day he had marked difficulty in opening his mouth and spasm in taking food. Had a free purge, followed by thirty grains of chloral hydrate every third hour in the form of an enema, to this was added bromide of potassium and digitalis, to avoid if possible the depressing effects of chloral. On the 5th the trismus had gradually increase, spasm appeared at every attempt to swallow, and food as well as medicine had to be given per rectum. On the following day the spasm was severe and long, the patient was hardly conscious; bathed in cold sweat. Rectum very irritable, neither food nor medicine being retained. On the 6th morning temperature 100·4°; just before death 103°.

Remarks.—This case ran a very rapid course, and was apparently uninfluenced by chloral in any way. The temperature and dressing proved that there was no septic absorption, so that this would lead to prove that it cannot have anything to do with tetanus, as some think. The amputation was well above the lacerated tissues, so that the tetanus was most unexpected. It seemed as though he was going to get rapidly well. When he complained on the fourth day, at first it was hoped that imagination might have something to do with it, as he had heard of the first case; but by the evening all doubt as to its nature was at an end, and chloral was at once given. At the necropsy about half a drachm of pus was found in a small abscess in the stump. Some might say this proved it not to be aseptic, but it was perfectly aseptic; still it was not suspected during life. I have had lately two other similar cases, but have no notes by me now.

SOUTHPORT INFIRMARY.

FATAL CASE OF DEPRESSED FRACTURE OF SKULL, WITH SLIGHT SYMPTOMS.

(Under the care of Dr. MCNICOLL.)

FOR the following notes we are indebted to Mr. A. J. Popert, house-surgeon.

On the evening of Nov. 11th last, in a drunken brawl, the patient, a woman aged forty, received a blow on the head from a small kitchen poker. She was not stunned, and thought little of it; her friends easily stopped the slight hæmorrhage that occurred from the small scalp-wound caused by the blow, and it was not until the morning of the 16th that she applied at the infirmary. She complained of soreness of the scalp. Upon examination a small sloughy wound, large enough to admit the top of the little finger, was found slightly to the left of the median line of frontal bone, and close to its upper border. The bone was denuded of periosteum. She was advised to enter the infirmary, which she did next day. A more careful examination then revealed the fact that an almost circular piece of bone, about the size of a sixpence, immediately beneath the wound, was slightly depressed. The depression, however, was so slight as to be more evident to the touch than to the eye. It was entirely surrounded by a faint line of fracture, but was not starred, and was quite immovable. Pressure on this spot caused no pain. The patient complained of slight frontal headache and nothing else. The pupils were normal, responding freely to light. Her temperature was 100°; pulse 90. Patient had not shivered.

On the 18th a consultation was held as to the expediency of trephining, and taking into consideration the fact that five days had elapsed since the receipt of the injury, and that the patient presented no symptoms beyond headache of an intermittent character, and a temperature of 101°, it was decided to wait.

Next day the evening temperature was 103°, and slight diarrhœa set in. This was checked by astringents, and the temperature again fell to 101°. From this time till Dec. 3rd patient's condition remained unchanged. She slept well, took her liquid food with good appetite, and except for the headache was fairly comfortable; but on the evening of this day she became rapidly comatose, and died in that condition about twenty-four hours after.

At the necropsy the external aspect of the cranial vault presented the appearances already described. On removing the skull-cap a comminuted fracture of the inner table was found; it was circular and rather larger than the corresponding depression of the external table, and consisted of three segments, the peripheral borders of all of which were free and sharp. The dura mater was bathed in creamy yellow pus, and on cutting this membrane several ounces of purulent fluid escaped. The whole of the right anterior lobe of cerebrum was disorganised, consisting of a dirty-brown semi-fluid mass; the cortex of the rest of this hemisphere showed signs of compression, but the left half brain seemed to be quite normal and healthy, nor had any pus found its way on this side of the head. All other organs were found to be healthy.

Remarks.—In this case the symptoms during life bore no proportion to the severity of the lesion, at no time did the patient present any of the clinical indications of acute meningitis; in fact, the only evidence of any mischief beyond the fracture were the headache and temperature; this fact alone makes the case of sufficient importance to record, and the question of trephining makes it additionally interesting.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

The Condition of Large Arteries after Ligature under Antiseptic and Non-antiseptic Measures.—Axillary Aneurism treated by Antiseptic Ligature of third part of Subclavian Artery; Partial Restoration of Lumen of Vessel.

THE ordinary meeting of this Society was held on the 8th inst., J. E. Erichsen, Esq., F.R.S., President, in the chair. Two papers illustrative of the inefficiency of the catgut ligature to produce permanent occlusion of arteries tied in their continuity were read, the one being contributed by Mr. Treves, and the other by Mr. M'Carthy. The main contention was that under antiseptics the changes around the vessels are too slight and temporary to aid in the occluding process.

A paper was read on "A Case illustrating the Condition of Large Arteries after Ligature under Antiseptic and Non-antiseptic Measures," by Mr. FREDERICK TREVES, of which the following is an abstract:—The specimens upon which the paper is founded consist—together with other parts—of the right carotid and subclavian arteries from a man, aged forty-seven, in whom those vessels had been ligatured for innominate aneurism. The patient gave a history of previous good health, and no definite date for the commencement of the local symptoms. A small aneurism of the innominate artery was diagnosed and ligature of its two branches resolved upon. On June 30th, 1880, the right carotid was ligatured above the omohyoid by Mr. James Adams, under whose care the patient was. The operation was performed under antiseptic precautions without hindrance or difficulty of any kind, a stout catgut ligature was used, and tied in a double and then a single hitch. The wound healed rapidly by first intention without the formation of a drop of pus, and in twelve days the antiseptic dressings were discontinued. After the operation the aneurism, although it did not diminish, ceased to increase. On July 21st, 1880, Mr. Treves ligatured the third part of the subclavian, the operation was also performed antiseptically, and the vessel was readily found; a stout catgut ligature was used and was tied in two simple hitches. During the night after the operation the patient loosened the antiseptic dressings and exposed the wound. On the evening of the next day he had a chill, the temperature rose to 101·6°, and the edges of the wound were red and swollen. The wounds began to suppurate very freely; the stitches had to be removed to allow of the freer discharge of pus, and in thirty-six days the incision was almost healed, having closed up from the bottom. The carotid incision may fairly be regarded as a type of healing under antiseptic measures, and the subclavian incision as an open suppurating wound. After the subclavian was tied the aneurism improved greatly, all the previous symptoms of discomfort gradually disappeared, and the man was discharged thirty-six days after the operation with the tumour apparently cured, or at least greatly benefited. He returned, however, on Oct. 14th, 1880, complaining of severe pain in the back, of cough, and of general feebleness, and was readmitted. After a slight attack of hæmoptysis the patient died suddenly two days after admission. At the time of death, therefore, 108 days had elapsed since the carotid was ligatured, and eighty-seven days since the subclavian operation. Death was found to be due to the rupture of an aneurism of the thoracic aorta; this had produced great destruction of some of the dorsal vertebræ. The great vessels were examined *in situ*. A small aneurism about the size of a Spanish chestnut was found connected with the innominate artery at its commencement; its sac was almost filled with laminated fibrin, leaving only a cavity about the size of a horse-bean in the centre of the tumour, and that communicated with the vessel. The brachio-cephalic vessel was quite patent, as were also the first portions at least of its two branches. In the region of the carotid operation the restoration of the parts to their normal condition was remarkable, the skin scar was slight and had formed no adhesions to the parts beneath, no trace of wound could be detected in the carotid sheath, no adhesions had formed between the artery and the vein, and every trace of the ligature had disappeared. No constriction could be seen in the vessel, and its external outline was unaltered and the seat of ligature indicated only by a faint transverse bluish mark on the vessel, due apparently to the thinness of the arterial coats in that situation. The vessel was found to be patent, but to be narrowed at the seat of ligature by a kind of perforated diaphragm or a miniature pylorus, leaving a central aperture about a line and a half in diameter. This diaphragm was formed by the incurvings of the ruptured ends of the middle coat, and as the external coat retained unaltered the external outline of the vessel, a minute triangular interval was thus formed, having its base represented only by the isolated external coat, and indicated by the bluish line, and its apex by the margin of the diaphragm, where the two cut ends of the middle coat met. As the two portions of the middle coat were only united to one another by the scantiest of connective tissues, the artery was very weak at the seat of ligature, and allowed of considerable angular bendings. The third part of the subclavian artery was found embedded in a mass of very firm inflammatory material, and was occluded for three-quarters of an inch, and entirely obliterated for half an inch. No trace of the ligature could be detected; the subclavian vein was patent. The aorta was very atheromatous, and the summit of its arch calcareous; the aperture leading from the aorta to the left carotid was extremely small, and that vessel was found to be occluded, save for a minute channel, through which air could only with some difficulty be forced. This unsuspected closure of the left carotid was evidently present at the time of the patient's admission, and much embarrassed the early diagnosis; for when the patient came under notice it was observed that the left temporal pulse was much feebler than the right, that the aneurismal bruit (most clearly marked over the innominate tumour) was more distinct in the left than in the right carotid, and that in the left vessel a thrill could be felt not noticeable in the right. These symptoms aroused strong suspicions of aneurism of the aortic arch, and are explained by the almost solid condition of the left carotid. As an operation for closing a bloodvessel the carotid operation must be considered to have failed, and the reasons of that failure are matters of great importance. In reviewing the subject Mr. Treves deals in detail with the comparative physiological condition of the two vessels at the time of ligature, and urges that in this respect the condition of the subclavian artery at the time of ligature was actually less favourable than was that of the carotid when subjected to operation. In the details of the two operations and in the health and general surroundings of the patient, no differences are apparent that could account for the differences in result. The conclusion, therefore, would appear to follow that the failure of the carotid ligature was due to the antiseptic measures adopted. It would appear that these measures might almost err on the side of perfection, by producing too ready and too complete a return of the parts to their condition previous to disturbance. Anatomically the healing of the wound was perfect, but would seem to have been too perfect for surgical purposes. A little so-called reaction in the wound, and a little of that firm inflammatory material almost too bountifully supplied about the subclavian incision, would probably have effected the permanent closure of the artery. The comparative risks, however, attending the healing of the two wounds are to be considered. The question remains as to whether, for some surgical purposes, the perfect healing aimed at by the supporters of the antiseptic treatment is desirable or successful.

The following is an abstract of the paper on "Aneurism of the Axillary Artery, probably ruptured; treated by Antiseptic Ligature of third part of Subclavian Artery; Partial

Restoration of Lumen of Vessel," by Mr. JEREMIAH M'CARTHY. F. G——, aged fifty-one, a sailor, was admitted into the London Hospital Sept. 7th, 1880. In 1879 he had been under the care of Mr. James Adams, for diffused aneurism of right popliteal artery, with the result of cessation of bruit and pulsation in the aneurism after eight hours' digital compression of the femoral artery. Five days later gangrene necessitated amputation above the knee. The wound had healed well, and the man was discharged cured in November, 1879. Ten days prior to his second admission he felt pain in the left axilla, which recurred on Sept. 6th with great intensity, and a swelling was observed in front of the left shoulder. There was a pulsating tumour immediately below the clavicle, which stretched the pectoral muscles, so that the man sat with his body bent forward. A loud bruit was heard over the swelling, and its pulsations were synchronous with those at the left wrist. It was evident that a small axillary aneurism had suddenly ruptured. The subclavian artery was at once ligatured antiseptically with a catgut ligature, arresting pulsation in the tumour and left wrist. In four days the tumour and the œdema had almost disappeared, and the wound healed by the eleventh day, when slight pulsation could be detected in the left radial. On the twenty-first day the patient complained of severe pain in the shoulder, and examination was made for its cause. A harsh bruit was heard below the inner third of the clavicle, but none in the consolidated mass close to the shoulder. An hypodermic injection relieved the pain. On the forty-second day the tumour was spreading towards the shoulder, and ice was tried externally and iodide of potassium internally; and on the forty-sixth day, on the supposition of the subclavian artery having become permeable, an examination was made, but no pulsation could be detected in the subclavian beyond the ligature. On the fifty-seventh day the arm became œdematous, the pulse at the wrist no longer perceptible, and the tumour steadily enlarging. On the sixty-second day the arm became of a dusky-red colour, some bullæ formed, and the tumour was obviously about to burst in the axilla. On the sixty-fourth day there was oozing of blood from the axilla, and Mr. M'Carthy amputated at the shoulder-joint. The pectoral muscles and parts of the axillary and brachial arteries were indistinguishable in the pultaceous mass, composed of old and recent blood-clots. The remains of the axillary aneurism could be seen with three large vessels opening into it, which, with five smaller vessels, were then tied. The man died one hour and a half afterwards. The author gave a full description of the post-mortem appearances of the subclavian artery and of the microscopic examination of its coats, which were much thickened at the seat of ligature, but there were no traces of the tunica intima having been completely divided, though in the media some of the elastic fibres had evidently been ruptured. The tunica adventitia was much thickened, and in it were imbedded the remains of the ligature surrounded by giant cells. With regard to the question how the artery became pervious, the author suggested that the catgut ligature applied with effectual antiseptic precautions to an artery in its continuity does not do sufficient injury to ensure the permanent closure of the vessel.

The PRESIDENT said the papers were of great value in the light they threw upon a subject of which so little was known—viz., the action of the catgut ligature upon the vessel when this is tied in its continuity. History repeats itself; for two generations ago it was probable that the efficacy of catgut and other animal ligatures was discussed at that Society. At the beginning of this century such ligatures were largely used; the ends cut short, and the wounds closed over the ligatures. Astley Cooper had a case where healing took place in four days. It would be interesting to know why the surgeons in those days abandoned these ligatures, for which such great expectations were raised. Probably it was because they were not found to be so trustworthy as the silk and hempen ligatures, which again came into vogue. At the present day, although catgut is specially prepared and the application of the ligature aided by modern science, it was remarkable that facts were pointing to the same conclusion as that formerly arrived at. That in each of the cases recorded there should have been this imperfect occlusion or reopening of the vessel, and formation of a sort of perforated diaphragm, was remarkable: it was a condition altogether unknown in his own experience of the ordinary ligature.—Mr. MORRANT BAKER asked why the author attributed the conditions found in the arteries to the mode of healing under antiseptics, rather than to the more reasonable fact that the ligatures had yielded after a certain time.—Mr. BARWELL said that the formation of a sort of diaphragm in an artery after ligature was quite new to him. In Mr. Treves's case no mention had been made of any internal clot above and below the seat of ligature (in the carotid), which used to be regarded as the chief protection against hæmorrhage. Could it be supposed that the antiseptic treatment prevented the formation of the clot, or the rupture of the inner coat, which determined such clotting. He suggested that a thin layer of fibrin might conceal the ruptured intima and convey the idea that this membrane had remained entire. Several instances had been recorded at the Clinical Society of the unreliability of catgut, which is liable to yield or to be absorbed too quickly; and this was a grave objection to its use. But if in the case the carotid had really been impervious for eighteen days, surely that was time enough for clotting to take place. Could one go so far as to say that the absence of an influence outside the vessel prevented clotting within it? He was surprised that ligature of the carotid should have been followed by increase in the force of the radial pulse, and more surprised at the increase of the opposite radial pulse after ligature of the subclavian in Mr. M'Carthy's case. The use of catgut, doeskin &c. was abandoned in old days because of the formation of abscesses around the ligatures. Although Astley Cooper's first case did well, his second case was followed by an abscess attributed to the ligature.—Mr. HULKE had twice tied the common femoral with catgut obtained from Edinburgh. The wound in each case did not heal by first intention, but a small sinus was left, causing much anxiety for some time; and it was his belief that if he had used the ordinary ligature he would have been spared that anxiety. He believed from the careful descriptions given that in neither of the cases recorded was the inner coat cut through; and if the inner coat were not divided, no clotting would ensue. However, we live now in revolutionary days, for we are told now that the clot is an accidental factor in the occlusion, which is said to be produced by the union of the opposed surfaces of granulations formed from the proliferating endothelium of the intima; and that the clot comes afterwards to strengthen the union.—Mr. GANT admitted that Mr. Treves's case showed that the open healing of the wound aided in the closure of the subclavian artery, but did not think the two operations comparable; that on the carotid being a simple incision, that required for ligature of the subclavian being a deep almost lacerated wound, where antiseptics were more likely to fail.—Dr. B. O'CONNOR said that ten or twelve years ago when dresser to Mr. Lister at Edinburgh, it was impressed on him that freshly prepared catgut was certain to slip when tied in a knot after soaking a short time in serum; and in his recent address Mr. Lister had again forcibly pointed this out.—Dr. J. HARLEY also pointed out that catgut by absorbing moisture must yield to pressure after a time unless most firmly applied.—Mr. T. SMITH said the cases were very valuable for confirming, if any further confirmation were needed, the untrustworthiness of carbolised catgut as a ligature for arteries in their continuity; and they supplied evidence as to the manner in which this takes place. He agreed with Mr. Baker that the whole failure could be explained by the ligatures not holding long enough. He could not doubt that if they had not yielded the coats would have been completely divided, and clotting taken place. Ever since he had a case where, in consequence of the failure of a catgut ligature (given him by Mr. Lister), followed by an aneurism at the seat of ligation, he had been in the habit of applying two such ligatures to an artery in continuity, and dividing the vessel between them. For the ligature can be trusted to severed arteries (as in amputation), but not to arteries where continuity remained. He had followed this plan for the brachial and femoral arteries, and had no trouble from secondary hæmorrhage. He could not believe that any process to which the catgut was submitted would make it a safe ligature. It was not by nature ever intended to resist tension in the longitudinal direction, and he feared it was vain labour to attempt to alter its nature. More fitting material might be found in tendons, which naturally resist tension; and he had been informed that kangaroo tendons (of which he understood some were in use in St. George's Hospital) were much employed in Melbourne and found to be thoroughly reliable.—Mr. HULKE explained that in speaking of the clot being only of secondary importance he was quoting the doctrines laid down in the ninth edition of Billroth's work, and not his own views.—Dr. GILBART SMITH asked whether the catgut ligature was likely to divide the inner coat, and whether such division was necessary or not to occlusion.—The PRESIDENT said that was the point on which James, of Philadelphia, tried to contest Jones's view that the inner coat must be divided, and the former urged that animal ligatures did not divide the internal coat.—Mr. BARWELL had made many experiments which convinced him that it was impossible to tie an artery with a round ligature without dividing the internal coat.—Mr. TREVES, in reply, said that he presumed loosening of the ligature might occur, but his point was that if there had been any inflammatory exudation around the vessel it would tend to keep the ligature applied; and in an antiseptic wound no such barrier occurred. There was absolutely no clot found in the vessel. The antiseptic failed in the case of the subclavian, because the patient had displaced the dressings. The inner coat appeared to have been divided and then reunited; there was no doubt that the middle coat had been severed. The division of the internal coat depended simply on the amount of force employed in tying the vessels.—Mr. M'CARTHY, in reply, thought too much stress had been laid on the mechanical action of the ligature, and that the reopening of the vessel was due to changes in the walls rather than the ligatures, which in his case had certainly not given way at the knot. The increased pulsation in the opposite radial was in accordance with physiological fact, and he related a case where such increased tension was observed by the sphygmograph to occur in the left radial artery to a certain extent when the right subclavian was tied, and to a much greater extent when this ligature was followed by ligature of the carotid, the case being one of innominate and aortic aneurism treated by ligature of these two vessels. If catgut were tied firmly enough it would divide the inner coat. In Mr. Adams' case, if this coat had been divided, a dissecting aneurism might have formed. There was microscopical evidence in his own case of proliferation of the intima; no clot was found, so that if it had formed it must have been swept away. The point of his case was that the changes in the adventitia did not proceed far enough, and the vessel yielded gradually to pressure, so that the channel was opened up again.—Mr. SAVORY asked Mr. TREVES if he had made any experiments or observations showing any difference between the healing of the wound in his case from that ordinarily known as healing by "first intention." If the process were the same, it did not alone explain why the vessel was not occluded.—Mr. TREVES said he had made no experiments.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Gunshot Wound of Brain.—Treatment of Suppuration in the Knee-joint.—Tumour of Hard Palate.—Sarcoma of Upper Jaw.

AT the meeting on Jan. 31st, F. J. Gant, Esq., President, in the chair, Dr. BRUNTON read notes of a Case of Gunshot Wound of the Brain, of twenty-nine years' standing, and exhibited the specimen. The present case, like all other cases of gunshot wound which had come under Dr. Brunton's care, was of suicidal origin. A lovers' quarrel resulted in an attempt to destroy his life by the discharge of a loaded pistol. A dangerous gunshot wound of the forehead was the consequence, followed by recovery without detection of the bullet, in fact the recovery was so satisfactory that it was assumed that either the charge in the pistol was blank, or if there were a bullet that it had glanced off. The patient carried on his ordinary business as a corn merchant for twenty-nine years. Subsequently his temperament was an excitable one, he married afterwards, and at his death left several children, all of whom are healthy. On the 23rd of March last, on being called to see him, the author found him in bed, suffering from double sciatica, for which he had been treated in the hospital. Marked relief followed treatment; but on the 5th of April paralysis of the bladder appeared, and continued until his death on the 19th of that month. On the 16th he was seen in consultation by Dr. Charlton Bastian; he was reduced in flesh, and, in spite of every precaution, suffered from bedsore. Wasting paralysis appeared a few days before his death, his intellect, however, remained clear to the last. On noticing an old cicatrix of an irregular shape over the left superciliary ridge at its inner aspect, by the root of the neck, inquiries as to its origin were made by the author, who, on hearing the story of the suicidal attempt, determined, if possible, to obtain an opportunity for searching for the bullet. Permission was with difficulty given accordingly to have an autopsy, the head only to be examined. On this being carried out membrane thickening and subarachnoid effusion of lymph were the external appearances found on the brain itself in the neighbourhood of the second and third left frontal convolutions. On examining the left frontal bone it was seen that the bullet had entered the bone at the inner part of the frontal sinus, passed through the outer, and lodged in the inner table projecting through it, and pressing on the membranes, destroying them *in situ*; and a portion of the second and third convolutions of the anterior lobe of the left cerebral hemisphere, exactly at the spot where the foreign body came in contact with these parts. There was no pus or artificial membrane, only a plain cavity lined by dura mater. The author remarked on the great rarity of this case; on its recovery, so rapid and complete, and upon the activity of the mental faculties, together with the healthy condition of his physical powers, and pointed out the absence of headache, notwithstanding the presence of the missile for so long a time.—Dr. GILBART SMITH thought this case remarkable and almost unique, as an instance of the tolerance shown by the brain to the presence of foreign matter. Cases of perfect recovery from lesions involving loss of substance of the brain itself, and especially of the frontal portion, were not rare, although somewhat difficult to understand; he mentioned the case of a photographer in Montreux, who received in the first Carlist war a sabre-thrust over the left eye followed by hernia cerebri. When seen by him some years ago, although an extensive cavity lay within an orifice situated at the bottom of a funnel-shaped depression an inch and a half deep in the forehead, yet his mental and physical faculties were unimpaired, and he followed his artistic occupation with great success. In reply to Mr. Pearce Gould, Dr. Gilbart Smith stated that the man was not left-handed, and this was shown by his having been aphasic for months after his wound.—Mr. ROYES BELL also considered this a rare case, and referred to the case of a boy from whom he had removed a bullet, in which perfect recovery ensued, although with considerable loss of brain-substance.—Dr. SYMES THOMPSON, in commenting on the case, referred to the celebrated "crowbar" case as an instance of the enormous damage sustained by the brain compatible with life.—Dr. BROADBENT observed that marked symptoms would not have been expected in this instance, seeing that only the extreme tip of the frontal lobe was injured. The death of the patient with acute cerebro-spinal mischief was remotely attributable to the bullet. The direction taken by the bullet gave the impression that the pistol was held in the left hand.—Dr. DOWSE said that the various cases mentioned went to prove that the anterior lobes have but little physiological value.—Dr. DAY thought these cases by no means uncommon, having seen many such in gunshot wounds. He thought that in some persons the brain showed a greater tendency to take offence than in others.

Mr. EDMUND OWEN showed three cases of "Knee-joint Abscess in Children." (These cases will be found described in full at p. 246.)

Dr. ALDER SMITH related a similar case recently treated by him at Christ's Hospital. The boy was admitted into the infirmary on September 15th, 1878, having previously had good health, and there was no history of injury. The symptoms resembled those of rheumatism; pain on movement, redness, swelling, but no effusion into the knee-joint. On September 22nd acute inflammatory symptoms set in; temperature 104°, and led to the opinion that an abscess had involved the joint. The limb was placed on a back splint. Next day there being no abatement of the serious symptoms, it was determined, in consultation with Mr. Langton, to thrust a trocar into the joint under carbolic spray. This was done and pus escaped, whereupon the joint was laid freely open on either side. Digital exploration of the joint revealed nothing abnormal. An india-rubber drainage-tube was placed through the joint underneath the patella, and the joint washed out with carbolic lotion. For a fortnight the limb was kept at rest in a swing back splint, and the joint syringed night and morning with carbolic lotion, and dressed with carbolic oil and lint. The constitutional symptoms subsided. On the fourteenth day the drainage-tube was removed. Till the 24th the joint freely suppurated, and the tissues about it enlarged; the lower end of the femur was much swollen. Next day, as necrosis appeared to be the cause, it was discussed, in consultation with Mr. Savory, where the limb would have to be amputated, rather than whether it could be saved. The same treatment, however, was continued, and by Nov. 9th the local and constitutional conditions were greatly improved. The discharge ceased on Nov. 21st. By February he was able to go into the country, and in a few months was playing about as usual. At the present time his joint, though larger than the left, is quite movable, and he is able to play cricket or football as well as ever. The case shows what an admirable result may occur after suppuration in a joint treated in the old method.—Mr. FRANCIS MASON thought the successful result in these cases depended rather upon the age of the children than on the treatment adopted, and asked if Mr. Owen would treat disease of the knee-joint in an adult in the same manner.—Mr. ROYES BELL alluded to two cases—one of wound of the knee-joint, and the other of an abscess secondary to necrosis of the tibia, which got well, under rest and dry application; but at the same time he considered that cases of suppuration of this joint did better when free incisions were made on each side with a drainage-tube passed across the joint; these incisions being done with strict antiseptic precautions. He though Mr. Mason's remark relative to adult cases judicious. Mr. Lister's method had the merit of enabling the surgeon to attack the disease in an early stage. The discharge came away through the drainage-tube, there was no tension from retaining discharge, there was less pain and less disturbance of the parts when the limb was dressed.—Mr. PEARCE GOULD remarked that Mr. Owen had laid stress upon his method of treatment as compared with Listerism; for his part, he considered a simple change of dressing under a spray once, or, at most, twice a week, more simple than the daily washing out of the joint, with more or less squeezing. The four cases shown, though exceedingly good, cannot be held to throw much light upon the discussion as to the value of Lister's treatment. Before that was introduced it was well known that such cases would recover, and it was important to remember that the mode of healing is the same in all cases, however dealt with. Mr. Lister's assertion is that by his method accidents, which sometimes, not always, follow wounds and inflammations, may be avoided. Could Mr. Owen show by his treatment there is less septicæmia and pyæmia than after Listerism?—The PRESIDENT, with reference to the question of age in relation to the efficiency of antiseptics in cases of joint disease or injury, mentioned the case of a man nearly fifty years of age who sustained compound dislocation of the elbow, with severe contusion from "buffer" injury. The wound closed after careful syringing with carbolic solution, and with but little purulent discharge. Recovery took place by nearly complete primary union, leaving a freely movable joint.—Mr. OWEN, in reply, said that his treatment for knee-joint abscesses in the adult was exactly the same as that which he had carried out in the case of these children, and he cited an instance in his own practice in which the treatment had been followed by an equally satisfactory result. He was aware that these three cases did nothing towards upsetting the value of surgical antiseptic treatment, but suggested that at any rate they were a contribution to the theory that perfectly satisfactory results can be obtained without the spray. He would not deny to any method, which involved early incision, free drainage and rest, equally good results. The cases had been desperately bad, and the benefit obtained by the treatment was no less decided. He had not brought them forward with any idea of "settling the grand question"; it would probably be long before the question was settled, but such results as these cannot be overlooked. He would not presume to reply to Mr. Gould's query, whether septicæmia and other grave complications would be more frequent if this method were carried out generally than if they were under special antiseptic treatment; but he held his own opinion on the matter.

Mr. FRANCIS MASON exhibited a man aged forty-two, whom he had shown at a meeting of the Society on Nov. 22nd, 1875. At that time he had a tumour involving the back of the hard palate, about the size of a walnut. Thirteen years previously he first noticed a small swelling, the size of a pea, in the centre of the hard palate. This gradually attained the size of a Tangerine orange. In 1875 he applied at St. Thomas's Hospital on account of some hæmorrhage from this part, which was arrested by perchloride of iron. There remained an ulcerated opening large enough to admit the forefinger; and the impression at the time was that the swelling was of cystic character. The patient being then in good health, and not suffering in any way, operative procedure was thought undesirable. The tumour now is steadily, but slowly, diminishing in size, and as it gives the patient no trouble he is content to allow it to remain as it is. There is little or no impairment of the voice.—Mr. MASON also exhibited a woman, aged fifty-two, the greater part of whose right upper jaw he had removed for Spindle-celled Sarcoma in April, 1877. The usual incision was made in the middle line of the lip, and the growth readily removed, the patient making a rapid recovery. She is now in fairly good health, and locally there is no return of the disease. She wears an artificial palate, which renders her speech perfect. The scar on the lip is scarcely perceptible; and Mr. Mason thought that this was due to the manner in which the incision was made, the knife having been first drawn lightly through the skin surface and the complete division effected by transfixing the remainder of the lip. It was customary, he added, to bring the edges of the lip together after such operations with harelip pins. He preferred the ordinary interrupted sutures of fine silk, which leave a smaller scar, and enable the surgeon to bring the parts into more accurate apposition.

Reviews and Notices of Books.

Diseases of Women. By T. GAILLARD THOMAS, M.D. Fifth Edition. London: Henry Kimpton.

THE work of Dr. Thomas was first published twelve years ago, and now it has reached a fifth edition, so that it must have obtained a hearty reception from the profession. The present edition is "thoroughly revised and enlarged," and evidently contains the mature views of the author. The character of the work is pretty well known to the student of gynæcology, as well as the views which the author holds on questions which still agitate the minds of obstetricians. Dr. Thomas belongs to that large class which holds uterine displacements to be morbid conditions of the highest importance, and mechanical and surgical means the panacea of suffering women. In proof of this statement we would adduce the following facts. In the chapters on anterior and posterior displacements alone there are at least fifty-two figures illustrating the displacements, the modes of reducing them, the instruments used in the reduction, and the instruments employed in maintaining the organ in the normal position. Surgical procedures are on all occasions described fully and minutely, while medical treatment receives but scant attention. Dr. Thomas is evidently a skilled manipulator as well as a dexterous operator, and it would seem that these accomplishments have led him to cultivate the mechanical and surgical aspect of the diseases of women at the expense of the medical, to the prejudice of his work and the injury of those who trust it as a guide. The parts devoted to mechanical and surgical treatment are by far the fullest and most elaborate in the work, and whatever differences of opinion may be held with regard to the directions given by the author as to *when* to operate, we do not think there will be any in respect of the mode of operating he recommends. The weak side of the work is its account of pathology and etiology; and unsatisfactory as our knowledge concerning these subjects is, yet we are somewhat surprised not to find any account of recent researches into the physiology and pathology of the uterus and ovaries when a whole chapter is devoted to the anatomy, physiology, and pathology of the perineum.

In discussing the pathology and etiology of diseases the author puts what he has to say into the form of tables which, at first sight, appear highly advantageous and satisfactory, but which, in practice, prove the very opposite. Many of the statements in these tables would be, and, indeed, are, called in question; but, setting aside this fact, the author has missed a great opportunity. To educe principles from collections of facts, and enunciate them, should be the first and greatest object of him who would aspire to teach any department of science. This work, on the other hand, would cram the student with facts, or what the writer supposes to be such.

There is a subject to which we would call attention, because in its discussion the first principles of medicine are lost sight of; and we notice it particularly as we believe it to be an error of the gravest character, and unfortunately inculcated and practised by many. We mean the unnecessary treatment of certain cases, many of which are absolutely free from danger or even from suffering. In the discussion of amenorrhœa we find no hint given that there are many cases of absence of the menstrual function, in otherwise healthy women, which should not be treated—cases in which emansio or suppressio mensium has given rise to no suffering of any kind, cases which it is not justifiable to treat, at least by means which may prove injurious, such as stem pessaries. In addition to constitutional means in the treatment of amenorrhœa this work recommends local stimuli, as tents, cupping, electricity, &c. Electricity is recommended, amongst other ways, in the form of a galvanic stem pessary; and the use of this instrument is recommended not only in amenorrhœa, but also in undeveloped and atrophied ovaries. With reference to these instruments we find it stated: "As these instruments must be left in place while the patients walk about there is always a danger of their irritating the walls of the uterus to too great an extent. To avoid this I have employed a stem composed of alternate bands of copper and zinc, held together by a small wire-rope, which passes through the centre of each, and is secured to the uppermost and to the vaginal disc below. This may by any movement of the uterus be bent at the required angle, and consequently can do no injury." We hardly think that the author means what is stated in the above passage, the danger of stem pessaries of all kinds being so well established, and so generally admitted. We cannot refrain from expressing our deep regret and astonishment that the distinguished author did not dwell fully upon the dangerous, in many cases fatal, character of stem pessaries. To recommend the use of such instruments in cases free from danger or suffering is in direct contravention of the first principle of medicine—"do no harm if you can do no good"—one which the teacher of gynæcology should in the present day be never weary of inculcating.

We have pointed out some of the blemishes as well as the excellences of this work; but we are disposed to think that even its excellences may produce bitter fruit in this over-surgical age, for the preponderance of mechanism and surgery over pathology and medicine cannot fail to have an injurious effect upon the student beginning the study of the diseases of women.

Elements of Practical Medicine. By ALFRED H. CARTER, M.D. London: H. K. Lewis. 1881.

THE student of medicine in the present day has to learn so much within so short a space of time that he is apt to fancy that he must practise economy in the matter of reading, and to view with dread the gradually-increasing size of the text-books he is recommended to study. All students are not constituted alike, and it is perhaps unfortunate that if they read at all they must either have recourse to ingeniously-contrived digests of the subject, which require to be committed to memory verbatim, or else be compelled to study the subject (in the truest and fullest way) by the perusal of works which require thought as well as memory to be called into action. Dr. Carter has aimed at meeting the wants of those whose inclinations do not lead them to study the larger and well-known text-books; and he has succeeded well in producing a work which contains the essentials of medicine stated in clear and explicit language, without overburdening the reader with side issues and disputed points. The task could not have been an easy one, for it necessitates the presentation of facts in a dogmatic way, and precludes any attempt at proving the statements. Dogmatism, however, lies at the root of successful teaching, and has often to be assumed without sufficient reason for the purpose of driving facts home to the learner's mind. He must be taught the types of disease; in time to come he will find out how varied are the departures from these types, and he will see that bedside experience does not always harmonise with statements that are laid down in books.

The work before us is one which meets a distinct want; and many will doubtless avail themselves of its perusal before proceeding deeper into the subject, whilst those who limit themselves to its pages will find therein sufficient to enable them to pass their examinations, provided, always, that they bestow large attention upon their clinical work. If one part of the book be more deserving of praise than another, the sections devoted to therapeutics might be especially singled out, supplemented, as they are, by several pages of formulæ at the end of the book, which, by the way, is devoid of any "index" in the ordinary acceptation of the term.

THE
GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

THE General Medical Council held a special sitting on Thursday, the 3rd inst., in order to transact business arising with reference to the Dentists Act of 1878.

The PRESIDENT, Dr. Acland, made a statement which appeared in our last week's issue as to the business to be brought before the Council.

Sir WM. GULL moved a resolution of condolence on the part of the Council with the widow and family of the late Mr. Andrew Wood. Occupying the position which Mr. Andrew Wood did as Chairman of their Business Committee, and considering how he had laboured from the very beginning of the Council most faithfully to advance the interests of medical education in this country, the Council would be wanting in its duty if it passed at once to the business before them without some expression of sympathy with Mr. Wood's family.

Sir JAMES PAGET seconded the resolution, which was unanimously agreed to.

Dr. HUMPHRY moved the election of the Business Committee, and said that on former occasions the election of that Committee had taken place almost in a formal manner, for they all had perfect confidence as to the efficient conduct of the business of the Council, as far as it lay in the hands of the Committee under the direction of its excellent chairman. Since that motion was put on a previous occasion a sudden visitation had inflicted the most irreparable loss which the Council could have sustained, in depriving it of the assistance of one of its oldest members. He could not bring forward this motion without expressing to some extent his feelings on the subject. It was not for them to sorrow altogether as men without hope for the future, for there still remained good and true men in the Council who would fill up the gap and carry on the work, he hoped, as heretofore. He proposed that the Business Committee should be elected, and should consist of the following members:—Dr. Pitman, Dr. Haldane, and Dr. Aquilla Smith, Dr. Pitman undertaking the duties of chairman. They could not have one more ready in his work, or more careful and considerate as to the wishes of the several members of the Council.

The resolution was seconded by Mr. TEALE, and was agreed to.

Dr. QUAIN moved, "That as, in accordance with Section 14 of Chapter 7 of the Standing Orders, it appears necessary that the election of an Executive Committee should take place on the first day of the meeting of the General Council that shall be held after the period of one year during which the Executive Committee continues in office, this Council, in accordance with Section 2 of Chapter 1 of the Standing Orders, resolves that the election of an Executive Committee be proceeded with, notwithstanding that such business has not been named in the summons convening the meeting of the Council." He said it was necessary to move this resolution, because a question arose whether the Executive Committee could be elected at a special meeting of the Council summoned for a special purpose, and they were advised by Mr. Ouvry that the best way of getting over the difficulty was by proposing a special resolution.

The resolution was seconded by Dr. AQUILLA SMITH, and agreed to.

The Council then proceeded to ballot for the Executive Committee. In the result the following members were declared appointed:—Sir James Paget, Dr. Pitman, Dr. Humphry, Dr. Haldane, Dr. Aquilla Smith, and Dr. Quain.

THE DENTISTS ACT.

The Report of the Dental Committee was then received and entered on the minutes. It stated that the Dental Committee having considered the corrected list of persons submitted to the General Council, and by the General Council referred to them for inquiry into the facts of the respective cases, had found certain facts with reference to them. It found, first, that certain persons in the list were at the time of making their declaration *bonâ fide* practising as dentists separately. Secondly, it found "the following persons have been registered on their declaration that they were *bonâ fide* engaged in the practice of dentistry in connexion with pharmacy, though the names of these persons are not to be found in the Pharmaceutical Register or in the Register of Chemists and Druggists. On application being duly made to these persons as to the grounds on which they had described themselves as practising dentistry in connexion with pharmacy, they have given explanations which show that they were managers, assistants, or apprentices to chemists and druggists, and considered that in that character they were practising pharmacy, and the Committee have no reason to doubt but that this was done from a misconception of the meaning of the Act, and without any fraudulent intention." Then followed a list of 115 names. After stating the facts with reference to a good many individual cases, the report gave a list of 68 persons who had at their own formal request been actually removed from the Dentists' Register. The report proceeded to state the particular cases. Cases which had been presented to counsel, together with counsel's opinion thereon, with regard to the Dentists Act, 1878, were then ordered to be read.

In answer to Mr. Simon,

Mr. OUVRY said he saw no objection to the publication of the opinions; they were very clear and decided, and were on matters affecting the public interest.

The first case was submitted to the Solicitor-General and Mr. Vaughan Hawkins, and the questions and opinions were as follow:—

QUESTIONS.	OPINION.
1. Must any proceedings to erase a name or qualification from the Dentists' Register, or to restore such thereto, be initiated by the General Medical Council?	1 & 2. We think that the power of initiating proceedings is vested in the General Medical Council, but that the Council may properly delegate to the Executive Committee, under the Medical Act, the power of receiving applications to the General Council, and of referring them to the Dental Committee under Sect. 15 of the Dentists Act, to investigate and report on the facts of the case, for the purpose of the matter being afterwards brought before the General Council.
2. Can the General Council delegate either to the Executive Committee under the Medical Act, or to the Dental Committee under the Dentists Act, a general power of initiating proceedings?	
3. Has the Dental Committee under the Act any power to originate proceedings?	3. We think the Dental Committee cannot itself originate proceedings.
4. Is the Dental Committee bound to hear the party interested before finding the facts?	4. We think the Dental Committee ought, before finding the facts, to give the party interested the opportunity of offering any explanations, and of being heard, if he desires it.
5. Where a person has procured his name to be put on the Dentists' Register as practising dentistry separately, but who, in fact, carries on some other trade, as a jeweller, hairdresser, &c., can the General Council remove his name from the Register?	5. We think that the name of a person cannot be removed from the Dentists' Register solely on the ground that he carries on some other trade, though the fact of his doing so might be material in considering whether he was *bonâ fide* engaged in the practice of dentistry at the passing of the Act.

Temple, August 6th, 1880.

FARRER HERSCHELL.
F. VAUGHAN HAWKINS.

CASE AND JOINT OPINION OF THE SOLICITOR-GENERAL AND MR. MUIR MACKENZIE.

The General Medical Council—Dentists Act.

The General Medical Council have carried out the registration of dentists in accordance with what they believed to be the meaning of the Act. Objections, however, have been raised which apply to the registration of persons who were registered on their declaration of having been in practice prior to the passing of the Act. These objections are founded more especially on the interpretation to be placed on Clause C of Section 6 of the Dentists Act.

Counsel are requested to advise the General Medical Council in reference to this section of the Act.

QUESTIONS.	OPINION.
1. What is the construction to be put upon the words "*bonâ fide* engaged in the practice of dentistry or dental surgery, either separately or in conjunction with the practice of medicine, surgery, or pharmacy?"	1. We are of opinion that the words "*bonâ fide* engaged in the practice of dentistry or dental surgery, either separately or in conjunction with the practice of medicine, surgery, or pharmacy," have no reference to any legal qualifications to practise medicine, surgery, or pharmacy. They are simply intended to indicate that if the person seeking registration is qualified to be registered by reason of his being *bonâ fide* in practice as a dentist, he is to be none the less so entitled because that is not his exclusive occupation, but is only carried on by him in conjunction with the practice of medicine, surgery, or pharmacy.
A. Do such words mean that a duly qualified dentist must be actually in business on his own account, or could a person otherwise duly qualified, and discharging all the duties of a dentist, but acting as assistant to another, be said to be *bonâ fide* engaged in the practice of dentistry?	A. We are of opinion that a duly qualified dentist need not necessarily be in business on his own account. If a person is discharging the duties of a dentist, and really practising as such, he is not disqualified from registration merely because he is acting as assistant to another. But he would be so if his duties consisted merely in rendering assistance to his employer, and not in the independent performance of dental operations.
B. Could a person competent of himself and duly qualified to practise medicine or surgery with dentistry, or	B. We are of opinion that the question whether the name of a dentist seeking to be registered in conjunction

to practise as a chemist and druggist and dentist, but whose name is not on the Medical Register nor on the Register of Pharmaceutical Chemists or of Chemists and Druggists, be said to be *bonâ fide* engaged in the practice of dentistry in conjunction with either medicine, surgery, or pharmacy?	with medicine, surgery, or pharmacy, is or is not on the Medical Register or the Pharmaceutical Register, is quite immaterial. The practitioner in dentistry is to be registered in respect of his dental qualifications only, and the Council need not inquire as to his right to practise medicine, surgery, or pharmacy.
C. Assuming that a person qualified as in the preceding clause can be registered in the form mentioned, will such person be disqualified from registration if acting as an assistant only?	C. The above answer applies to this question. It is immaterial whether the person seeking registration in conjunction with medicine, &c., is an assistant or not, provided he possesses the requisite dental qualifications.
D. Can apprentices to chemists practising also dentistry claim to be registered under the Dentists Act as *bonâ fide* practising dentistry in conjunction with pharmacy?	D. We think that apprentices to chemists practising dentistry cannot claim to be registered as *bonâ fide* practising dentistry in conjunction with pharmacy. The 37th section provides for the registration of apprentices and students in certain specified cases, but except in the cases provided for in that section we do not think that apprentices can claim registration.
E. Can a person duly qualified to practise dentistry claim to be registered in conjunction with pharmacy on the ground of his practising some form of pharmacy such as homœopathic or veterinary pharmacy?	E. We think it is immaterial what form of pharmacy a person practises, provided he satisfies the dental qualifications necessary for registration.
2. Much misconception having arisen on the part of persons applying to be registered under Clause (C) of Section 6 of the Dentists Act, as to the interpretation to be put on the words of that clause, and application having been made to the General Medical Council to strike off the Dentists' Register the names of persons stated to have made false declarations in connexion therewith, counsel are requested to advise on the following questions:	
A. Whether a person can claim to be registered on filling up the declaration as printed in the schedule to the Dentists Act, and nothing more?	A. We are of opinion that a person can claim to be registered under Clause C of Section 6 on signing, as prescribed in Section 7, the declaration in the schedule to the Act. The Registrar may, if he thinks fit, require the declaration to be affirmed by a statutory declaration, as provided by Section 7, but nothing more can be required.
B. Whether the General Medical Council can, at the request of persons now registered, omit from the Dentists' Register the words "with pharmacy," or any additional qualification that may have been entered on the Register, if the Council be satisfied that the request for insertion has been made through inadvertence or misconception?	B. The General Medical Council can, in our opinion, omit from the Dentists' Register the words "with pharmacy," or any like words, in every case in which they think proper to do so. Such words are, in our opinion, superfluous, and should not have been placed on the Register at all. The Register should, in our opinion, contain the names of the practitioners, with any dental diplomas or qualifications to which they may be entitled, but should not contain any reference to their qualifications or practice either in medicine, surgery, or pharmacy.
C. Can the Council require proof to be furnished of any additional qualification required to be registered, such as the production of any diploma, degree, or licence of any medical or surgical body, college, or institution?	C. We think that the only additional qualifications which should appear on the Register are those which express or imply fitness to practise dentistry (Section 11, Clauses 2 and 6). If a candidate for registration desires to have such additional qualifications registered, we think that the Council can certainly require proof of such qualifications by the production of the necessary diploma, degree, or licence.
D. In the absence of such evidence has the General Medical Council power to remove the words "in conjunction with medicine," &c., from the Dentists' Register?	D. We have already said that we think that the Council have full power to remove from the Register the words "in conjunction with medicine." We think further that in any case in which the Register contains incorrect statements of a dentist's qualifications, the incorrect statement may, under Section 13, be erased.

FARRER HERSCHELL.
Temple, Dec. 14th, 1880. MONTAGUE MUIR MACKENZIE.

With respect to the Reports by the Dental Committee and counsel's opinion, the Executive Committee thought that it might facilitate the action of the Council if it instructed Mr. Ouvry, the Council's solicitor, to indicate some of the results which appeared to follow from the advice given by counsel, as affecting the facts stated in the Reports.

On the motion of Professor TURNER, seconded by Dr. PITMAN, it was resolved that Mr. Ouvry's remarks should be placed upon the Minutes. They were as follows:—

"These Reports deal solely with facts, and the finding of the Committee as to such facts is, by the Dentists Act, conclusive on the General Council. The General Council has therefore to consider whether the facts so found call upon the Council in any of the cases under consideration either (1) To remove the names from the Dentists' Register; or, (2) To amend the entries in the Register with respect to such names. The great majority of the cases included in these Reports are those in which persons are registered on declarations made by them that they were practising dentistry with pharmacy, or with medicine or surgery, and in each and every case the facts are found by the Dental Committee. A distinction is made between those cases wherein the persons are either on the Pharmaceutical Register or on the Register of Chemists and Druggists, and the cases of those whose names do not appear in such Registers, but who still practise pharmacy in some form or other. The Dental Committee find no fraud in any of these cases. The Council will therefore have to consider whether, in the absence of fraud, the names of such persons should be struck off the Register, even if the Council should (1) Consider that such persons had inaccurately described themselves as practising pharmacy, medicine, or surgery; or, (2) Assuming it to find that such inaccuracy existed, should amend the Register by striking out therefrom the words 'with pharmacy,' 'with medicine,' or 'with surgery,' as the case may be. In determining these questions, the opinion of counsel has an important bearing. It will be seen that counsel express the opinion that the additional words above referred to are superfluous, and should not have been placed on the Register at all; and, further, that the Council has power to amend the Register by striking out such superfluous words. In fact, the opinion is that the Dentists' Register should contain the names of the practitioners, with any dental diplomas or qualifications to which they may be entitled, but should not contain any reference to other qualifications or practice in either medicine, surgery, or pharmacy; and that whether the name of a dentist seeking to be registered in conjunction with medicine, surgery, or pharmacy, is or is not on the Medical, Pharmaceutical, or Chemists and Druggists' Register, is quite immaterial. The practitioner in dentistry is to be registered in respect of his dental qualifications only, and the Council need not inquire as to his right to practise medicine, surgery, or pharmacy. It is further advised by counsel that a duly qualified dentist need not necessarily be in business on his own account, and that if a person is discharging the duties of a dentist, and really practising as such, he is not disqualified from registration merely because he is acting as assistant to another; but he would be so if his duties consisted merely in rendering assistance to his employer, and not in the independent performance of dental operations. This opinion of counsel on these several points may probably lead the Council to consider whether going beyond the names included in the reports of the Dental Committee the whole Register does not require to be amended, by striking out all reference to pharmacy, medicine, or surgery, allowing only the dental qualification to remain."

Dr. HUMPHRY said, for the purpose of taking practical action upon what had been presented to them, he had given notice of motion to the following effect: "That all qualifications now appearing in the Dentists' Register other than dental qualifications be erased therefrom." Anyone could be registered who at the passing of the Act was *bonâ fide* engaged in the practice of dentistry or dental surgery, either separately or in conjunction with the practice of medicine, surgery, or pharmacy; and as the Council thought in accordance with the clause of the Act, it issued a schedule differing somewhat from the schedule under the Act, and containing the following rider—"Is at the passing of this Act *bonâ fide* engaged in the practice of dentistry or dental surgery, either separately or in conjunction with the practice of medicine, surgery, or pharmacy." That schedule went forth into the world. They had now taken counsel's opinion, and it was to the effect that the Register was as stated in the Act, a Dentists' Register, and meant that and nothing more, and that they had no right to require anything more, or to insert anything more in the Register. That appeared clearly in counsel's opinion, and also in the statement made by Mr. Ouvry. It seemed perfectly clear that there never should have been any entry in the Register except those relating to dentistry. Then came the further question whether they should expunge those entries from the Register; it was clear that they had the power to do so, and to amend the Register by striking out these additions, and it seemed very important that they should do, for it would put an end to all questions which had arisen in such a large number of cases, as to whether persons were properly entered in the Register, or whether they had by misconception or by fraud added the words, "in dentistry, in medicine, and surgery." It was very important that the Dentists' Register should contain dental qualifications and no other, and for this reason, that they had no right to inquire whether those other qualifications were legal or not. He begged to move the resolution of which he had given notice.

The resolution was seconded by Dr. FERGUS.

Dr. MACNAMARA said, while agreeing with all that had fallen from the lips of the proposer of the resolution, he wished it to be understood that he did not subscribe to the doctrine, if that was involved in the statement they had heard, that the Council would go quite far enough by carrying this resolution, because unquestionably there were some men who had got on the Register by stating that which was absolutely false—they had obtained the titles "with medicine and surgery" through fraud, and with a declaration that they were practising dentistry in connexion with pharmacy, or surgery, or medicine. There were several cases where persons appeared on the Register as practising dentistry in connexion with medicine when they knew they were not, and now they wished to have their names taken off, stating that it had been done through inadvertence. How could they be so stupid as to practise dentistry "with medicine" when they knew they were not doing so; and now when they absolutely cried *peccavi* were they to escape any punishment whatever for making that which was a false assertion?

Dr. QUAIN said that the Dental Committee had found that there had been no fraud in any one case referred to by them.

Dr. AQUILLA SMITH observed that Mr. Macnamara had entirely misread the words of the motion. He had assumed that some of these men had acted fraudulently in getting their qualifications. The Council had nothing to do with that, the motion was simply to strike out the qualifications, and if the fraud was committed the names would remain on the Register, and they would be just as open to penalty and erasure hereafter. It would be a great waste of time to inquire how these qualifications were put on; the simple fact was that they were on the Dentists' Register, and counsel had distinctly advised that they should be removed.

The PRESIDENT said the motion before the Council was that the Dentists' Register be amended by removing from it all other than dental qualifications. That had no relation to individual cases which came before them in another category. They were not discussing whether persons were guilty of fraud, because that was entirely beyond the province of the Council. The law was that a committee was to judge as to the facts of the cases, and to submit them to the Council. It was for the Council to decide what should take place upon those facts, but they could not discuss the guilt or innocence of persons who had been adjudged by the committee not to be guilty of fraud.

Mr. SIMON asked whether the Council had no opportunity of judging whether the facts submitted to them constituted fraud.

Mr. OUVRY said the committee had investigated the facts. They had communicated with each of the gentlemen referred to and had received their answers, and they found as a fact that their declarations were not made fraudulently. He took it that that fact was binding on the Council just as any other fact found by the committee would be. If it were not so the Council would have to investigate the thousand letters that he had received from those gentlemen, and to found their opinion upon them as to whether they had made their application from a mistake or from actual fraud.

Sir WM. GULL, in supporting Dr. Humphry's motion, said it was quite beside the question to add any qualifications in the Dentists' Register as to a man's practising medicine, or surgery, or pharmacy. They might just as well insert that he was a farmer or a hairdresser, and so make the Register look ridiculous. They must therefore leave out all qualifications except such as related to dentistry.

Prof. TURNER said no doubt Dr. Humphry's motion would enormously simplify the Register, and their excellent Registrar would be only too delighted to have this burden removed from his shoulders. He, however, could not help, without in the least throwing any doubt upon the Council, inquiring why the words "Or in conjunction with the practice of surgery, medicine, or pharmacy" were put into the Act. There was an expression in a letter from Mr. Tomes which they ought not to pass over. Mr. Tomes was the moving spirit in the framing of this Bill, and it was under his auspices that the Bill was introduced. There was no doubt at all, from an expression in the letter, as to what was in Mr. Tomes' mind when the words "Either separately or in conjunction with medicine, surgery, or pharmacy" were introduced into the Bill. Mr. Tomes said, "The end might be gained by the use of an initial letter or by an asterisk; but it would be far better to use for the purpose the words of the Act—viz., 'In practice before July 29th, 1878, in conjunction with pharmacy, or medicine, or surgery, as the case might be,' and this would, at the same time, carry out most perfectly both the letter and spirit of the Dentists Act." From those words it was obviously in the mind of Mr. Tomes that there should be some indication in the Dentists' Register bearing on these matters. Why, then, were they put in the Act, unless they were to be brought permanently forward in the Dentists' Register? What information had the Medical Council on this question as to whether a person applying to be registered under Clause C was simply a dentist, or was a dentist and something more? They could have no information unless they asked for it, and it certainly seemed as if by the clause in the Act they were required to ask for it. If not, he could not understand why the alternative proposition was put into the clause.

Dr. SCOTT ORR said they could not ask what people meant in framing an Act of Parliament. The Council was no doubt desirous of registering higher qualifications than dentistry, and passed a resolution to that effect, which he had certainly opposed. Now that counsel's opinion had been given to the effect that they could only register dental qualifications, they must undoubtedly act up to that opinion.

It being four o'clock, the discussion was adjourned for a short time in order that the Council might deal with the case of Mr. John Hamilton, of 404, Oxford-street, who had been summoned to appear before them at that hour. The facts of the case are contained in the Report of the Dental Committee. Mr. Hamilton did not appear, and the Council, deliberating in private, resolved to erase his name from the Register.

Dr. STORRAR, in resuming the discussion upon Dr. Humphry's motion, said Professor Turner had made an allusion to the wishes and intentions of Mr. Tomes and the Association with which his name was identified. Mr. Tomes was a personal friend of his own; he knew his feelings upon this subject, and he felt that knowing them he ought to state those views, and the views of those with whom Mr. Tomes was associated as far as he could. Their great desire was to raise the position of their profession and to purge out a number of loose persons whom they knew took refuge in the profession of dentistry. At the same time it was their great wish not to be so limited as to exclude persons engaged as pharmaceutists, and who were to a certain extent practising as dentists. They found, when the period came for registration, a perfect rush of persons—he believed he should not be wrong in saying that more than double the number of persons presented themselves for registration than had been expected by Mr. Tomes and his coadjutors. Persons came forward and got themselves registered as dentists merely for the purpose of escaping being summoned on juries. Mr. Tomes and his friends not unreasonably thought that if persons declared themselves to be practising as dentists along with pharmacy, and their names did not appear on the Register of the Pharmaceutical Society, that would be a fair *primâ facie* ground for their removal. But the schedule which described the form of application did not carry out that intention, and the result was no doubt inevitable. It occurred to him whether it might be possible for the Registrar to make more ample use of the statutory declaration which it would be in his power to impose. There were many men who would come forward to sign an ordinary declaration such as the one contained in the schedule, who would probably think twice before committing themselves to a statutory declaration.

Dr. QUAIN said he quite agreed with the praise that Dr. Storrar had accorded to Mr. Tomes and his good intentions. The Council had nothing to do with intentions; they had only to deal with the Act of Parliament before them, and nothing could be clearer than the opinions expressed by those whom they have consulted. Mr. Tomes and his friends had tried impossibilities; they had tried to induce Parliament to say that a man should be engaged separately as a dentist and nothing else. Parliament would never consent to such a law as that.

Dr. HUMPHRY said, in reply, that he was glad that the Council had endeavoured to carry out the spirit of the Act in accordance with the intentions of those who framed it, and that they had acted when they made their first Dentists' Register in accordance with these intentions. There was, however, this consolation to be taken, that as time went on these evil things would gradually become less and less, and that ultimately, after the lapse of a certain number of years, those only would be admitted to the Register who had a qualification obtained from some of the medical authorities. It had been pointed out that the words of the resolution required some alteration. He would propose to alter the resolution in this way: "That all statements with reference to the practice of medicine and surgery and pharmacy now appearing in the Dentists' Register be erased therefrom." It did not alter the intention of the resolution, but simply put the words in a somewhat different form.

Dr. FERGUS agreed to the alteration; and if the Council would permit it it would more fully express their intentions.

The resolution as amended was put to the Council, and agreed to.

Dr. PITMAN moved, "That the Council is not in possession of evidence to show that any of the registered dentists named in the 'corrected list of persons' submitted by the honorary secretary of the British Dental Association (set forth in pp. 245 to 248 of vol. xvii. of the Council's Minutes), or of the registered dentists named in the letter of Dr. Jacob (Minutes, vol. xvii., p. 256), were not, at the time of their registration, *bonâ fide* engaged in the practice of dentistry, and is therefore not prepared to order the removal of any such person from the Dentists' Register." He said that the Council could scarcely pass any opinion on the facts set forth by the Dental Committee, but they must accept, and he hoped would accept, the motion which he proposed.

The resolution was seconded by Dr. AQUILLA SMITH.

Mr. SIMON said the form of the resolution did not refer to the preceding Report of the Dental Committee, upon which it was founded.

Dr. PITMAN said if they read the Report they would find it went fully into every question, and gave reasons for believing that the applications were not fraudulently made.

Dr. QUAIN said there was no evidence that any one of these men had obtained registration except on a declaration that he was *bonâ fide* engaged in the practice of dentistry, and the registrar registered no one who did not produce evidence to him which he deemed sufficient to show that he was *bonâ fide* engaged in the practice of dentistry. Therefore, until it was proved that he was not *bonâ fide* engaged in the practice, everyone of these persons must remain on the Register.

The PRESIDENT stated that the notice of motion had been drawn up with great care by the solicitor, and it was a statement, as far as it went, of that which the committee had in evidence, but it did not extend further. The committee had been very careful to state nothing beyond the facts which they had in their possession.

Mr. MACNAMARA said that any resolution which would sanction the retention of some of the names returned on the Dental Register could not meet with his approval. He wished to know if all the names printed in the Report were covered by the resolution. ("No, no.") What names, then, were? Mr. Simon had asked the question, and the answer was not at all satisfactory. He desired to have a clear, distinct statement as to what names were covered by the resolution.

Dr. PITMAN said the resolution referred to two lists set forth in pp. 245 to 248 of vol. xvii. of the Council's Minutes.

A few additional suggestions having been offered the resolution was eventually agreed to in the following form:—"That the Report of the Dental Committee not having put the Council in possession of evidence to show that any of the registered dentists named in the 'corrected list of persons' submitted by the honorary secretary of the British Dental Association (set forth in pp. 245 to 248 of vol. xvii. of the Council's Minutes), or of the registered dentists named in the letter of Dr. Jacob (Minutes, vol. xvii., p. 256), were not, at the time of their registration, *bonâ fide* engaged in the practice of dentistry, the Council is therefore not prepared to order the removal of any such persons from the Dentists' Register."

Dr. HUMPHRY moved "That the persons mentioned in Clause 5 of the Dental Committee's Report as having been actually removed from the Register at their own request, be, on their application, restored to the Register without fee, subject to the discretion of the Executive Committee as to the grounds on which their names were so removed." On reference to the Report it would be seen that the persons referred to were, first, those who had withdrawn their names in consequence of receiving threatening letters from the secretary of the British Dental Association. Those threatening letters had reference to the fact of their having registered as pharmaceutists without being on the Pharmaceutical Register; secondly, persons who had discontinued the practice of dentistry and pharmacy; thirdly, those who had withdrawn their names through misapprehension; and, fourthly, chemists' and druggists' assistants. The majority of these had withdrawn their names in consequence of a misapprehension into which they were led by the Council's schedule, and under those circumstances it was only right that they should, on application, be allowed to have their names restored without fee. The Council had decided that five shillings should be paid for such restoration, but under the circumstances of the present case he proposed that the names should be restored without payment of any fee, "subject to the discretion of the Executive Committee as to the grounds on which their names were so removed." The legal opinion in regard to chemists' and druggists' assistants or managers was, "We are of opinion that duly qualified dentists need not necessarily be in business on their own account." It was manifest, therefore, that all these persons had withdrawn their names under a misconception which was in part shared by the Council, and it was only reasonable that they should be allowed, if they so desired, to have their names restored to the Register, subject to the discretion of the Executive Committee.

Dr. QUAIN seconded the resolution.

Dr. AQUILLA SMITH regretted he could not vote for it. He quite admitted that those gentlemen withdrew their names under a misapprehension, but the Act said that the name of any person erased from the Dentists' Register at his own request or with his consent might be restored to the Register on his application and payment of a fee not exceeding the fee fixed by the Council; that fee was five shillings. No mention was made in the Act whatever as to the circumstances of the withdrawal, and unless the standing order relating to the fee was rescinded he did not think the motion could be agreed to.

Dr. FERGUS said the power of fixing the fee was in the hands of the Council, and therefore he could not see why they could not dispense with it in the present case.

Mr. SIMON said their present position was a somewhat humiliating one, but if they had led other people into error, of course it was desirable they should endeavour, so far as they could, to remedy it. He suggested that if it was thought fit to pass the proposed resolution some words should be added, such as the following: "And the grounds on which registration is claimed." It should be left open to the Executive Committee to review the cases. Of course, if the Council was responsible for these names being taken off the Register when they ought not to have been there should be no charge for reinstating them.

On the motion of Dr. AQUILLA SMITH, the standing order referring to the fees was suspended for the time being, and the resolution was agreed to, with the addition of the words suggested by Mr. Simon.

Dr. AQUILLA SMITH proposed, "That no evidence has been adduced to justify the removal from the Register of the name of Christian Friedrich Wilhelm Ackermann, whose case is set forth in Clause 17 of the Dental Committee's Report."

Sir JAMES PAGET seconded the motion.

Mr. MACNAMARA said this was one of the cases to which he must object. The Council was a deliberative assembly, and surely they were not going to proclaim to the world that dental surgery and dentistry consisted of nothing but the extraction of a few teeth, and that a man might be a dentist whose occupation seemed to be dressing hair and whose wife kept a tobacco-shop. In the interests of the dental profession and of surgery he most earnestly protested against the retention of such a person's name on the Register.

Dr. QUAIN said he thought Mr. Macnamara had seen those two persons, and must have noticed their intelligence and truthfulness. One of them had been engaged for three years in connexion with the German hospitals and the German army, and his father practised as a dentist before him. The person referred to in the resolution said, on being questioned, that he had pulled out six hundred and twelve teeth last year, and the impression left on the mind of the Council appeared to be that they would much rather have him extract their teeth than many of those whose names had been left on the Register. What was dentistry? It was true that dentistry had now extended to stopping and scraping teeth, but the reputation of the celebrated Cartwright himself was entirely founded on the pulling out of teeth. The men to whom Mr. Macnamara objected to were apparently men of great intelligence, and he could not, and would not, vote for their names being omitted.

Mr. SIMON trusted that Dr. Aquilla Smith would see his way to alter the form of the resolution, and let it read to the effect that the Council was advised that there did not exist a legal case for removing these gentlemen from the Register. It would be quite consistent to say that no evidence had been adduced justifying the removal of the names. The Act considered that it was expedient that provision should be made for the registration of persons specially qualified to practise as dentists, and he could not conscientiously say that there was any reason to remove the name of a man because he merely extracted teeth. He bowed unreservedly to the legal opinion, but he hoped the resolution would be so framed as to show that the Council was simply acting mechanically in obedience to the law. He would suggest that the resolution should read, "That no legal case exists for the removal," &c.

The PRESIDENT considered the word "evidence" bore that signification.

Mr. SIMON thought that evidence in a medical sense had been adduced, but in a legal sense it had not.

Dr. AQUILLA SMITH said the persons had answered in a very straightforward way the questions put to them, and the conviction of the Council was that they were more competent than many whose names were retained on the Register. He did not object to Mr. Simon's suggestion.

Sir WILLIAM GULL said he should be sorry if it went forth to the world that they as medical men had decided that dentistry was nothing but extracting teeth; dentistry consisted in preserving teeth.

The PRESIDENT said Mr. Ouvry had suggested that the resolution might read, "That on the evidence the Council do not see sufficient legal grounds on which to direct the removal from the Register," &c. That would leave it open to full discussion on medical grounds hereafter.

The resolution so altered was seconded by Sir JAMES PAGET and agreed to, as was also the following resolution:—"That on the evidence the Council do not see sufficient legal grounds on which to direct the removal from the Register of the name of August Leopold, whose case is set forth in the Dental Committee's report."

Dr. AQUILLA SMITH then moved, "With regard to Alexander Schocke, mentioned in Clause 19 of the Dental Committee's Report, there is no evidence before the Council on which it can act."

Dr. PITMAN seconded the motion.

Mr. OUVRY said that the person referred to had shut up his shop, and could not be summoned to attend; but he had gained courage, and reopened his shop.

The PRESIDENT said a new procedure was necessary under those circumstances, but at present there was no evidence which the Council could act upon.

The resolution was agreed to.

On the motion of Dr. PITMAN, seconded by Dr. AQUILLA SMITH, the following returns were entered on the Minutes:

Table showing Results of Professional Examinations held in 1880 for Qualifications granted under the Dentists Act.

Name of Licensing Body.	Diplomas.	Nature of Examination.	With Curriculum.		Without Curriculum.		Total.	
			Number Rejected.	Number Passed.	Number Rejected.	Number Passed.	Number Rejected.	Number Passed.
Royal College of Surgeons of England.	Licence in Dental Surgery.	Written, Practical, and *vivâ voce.*	1	17	0	1	1	18
Royal College of Surgeons of Edinburgh.	Licence in Dental Surgery.	Written and Oral.	0	1	0	4	0	5
Faculty of Physicians & Surgeons of Glasg.	Licence in Dental Surgery.	Written, Oral, and Practical.	0	0	11	23	11	23

University of Harvard.	D.D.M.	Written & Practical.	5	11	0	0	5	11
		Totals...	6	29	19	75	25	104

The Council then adjourned for a short time, and on their return the Minutes of the previous meeting were read and confirmed.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 12, 1881.

DR. JAMES GREY GLOVER—whose name has for many years past been prominently associated with the question of Medical Reform, and who may be held to speak in the name and to represent the interests of the great body of general practitioners—has published a letter addressed by him to the Right Hon. A. J. MUNDELLA, M.P., Vice-President of the Council. Dr. GLOVER'S object is to urge upon the Government the need of prompt action, either by the adoption of a substantive proposal to Parliament, or by the reappointment of a Select Committee, with a view to the adequate solution of the vexed questions of medical education and the registration of professional qualifications. The "letter" puts the issue so clearly and tersely, that we let it speak for itself.

"Legislation contemplated by medical reformers has two principal objects. One of these is the improvement of the examining machinery for licensing persons to practise the medical art in all its branches. The second is an improvement in the constitution of the General Medical Council of Education and Registration, by which it shall be made more effective as a council; firstly of medical education, and secondly of medical registration. 1. As you are doubtless aware, owing to the one-sided nature of the medical corporations at present, nearly all the diplomas given by the bodies are only half diplomas, half qualifications, and for giving even these there is among nineteen bodies a certain amount of injurious competition, so that it is notorious that persons rejected in one part of the kingdom find easy entrance to the profession in another; or, rejected by a university, find ready admission into the profession through a corporation. These half diplomas admit to the Register, and, as a matter of fact, large numbers of practitioners have paid a great price for this imperfect document—a price for which they should have obtained a complete diploma. By the existence of such a system of half qualifications two parties are injured—the practitioner who finds himself legally unqualified for half his duties by the one-sided nature of his diploma, supposing him to have but one, and the public, who have not in such diplomas the guarantee of competence in all essential subjects of medical knowledge which a licence should imply. . . . . . 2. The reform of the Medical Council is the other and very urgent demand of a great majority of medical men, expressed in several great memorials to the Government and the Medical Council. The Medical Council exists chiefly for the purpose of controlling the education of the general practitioners of the country, and these practitioners have no direct representatives on it. Of twenty-three members of the Council, seventeen represent the educating and examining bodies, and are committed to the defence of the interests of these bodies, several of which are admittedly useless, and unfitted for further work. The remaining six members of the Council are nominated by Her Majesty, with the advice of her Privy Council. There is, besides these, a President, chosen by the Council. At the time of the passing of the Act of 1858, there was an understanding that the Crown appointments would be made out of the rank and file of the profession, which would have secured the representation of the body of general practitioners. Unfortunately, with one or two exceptions, gentlemen have been chosen for these appointments who are officially connected with medical schools or corporations, and so have only intensified the representation of pecuniary 'interests' in the Council. Thus it has come to pass that after twenty-two years' existence, and a very large expenditure of money, medical education is still in a very costly and inefficient state. Until the appointment of the Select Committee successive Governments had no opportunity of learning how this Medical Council did its work, or rather did not do it. Some light was then let in on its costly debates, constantly recurring on the same subjects, and only ending in recommendations, not binding on the educational or examining bodies. But the dissolution of Parliament, unfortunately, dissolved the Committee, and the eyes of all medical reformers are looking for its reappointment, or for legislation calculated to remedy the evils which have been exposed."

This very fairly states the present position of affairs, and may be accepted as representing the view taken of the situation by the profession at large. No measure can be satisfactory which does not in some way provide for the improvement of medical education. We have had, and the public has had, a sufficiently long experience of self-government by privilege. The licensing bodies have been supplied with a legally-created opportunity of improving themselves, and they have found their enjoyment in trifling with the intentions of the Legislature and the wishes of the profession and the community. They have been encouraged in this pastime—which SCHLEIDEN defined as waste of time—by the organisation so singularly misnamed "The Council of Medical Education." There is no time for further trifling; the period for action has arrived. "Priusquam incipias consulto, et, ubi consulueris; mature, facto opus est." There has been overmuch consultation; it is now necessary to *do* something. Ministers of the Crown and members of Parliament having no personal interest in the question of medical reform, or not recognising the intensely personal interest which every member of the population undoubtedly has in the subject, are asking whether medical reform will advantage the cause of public health, or provide better treatment for laymen in the hour of sickness? These are precisely the ends we seek to gain. If any member of Parliament broached the subject of medical reform in a private gathering of medical men, or proposed the question to his own medical attendant, he would receive the impression that it was *not* a burning question. This is one of the most significant facts about the movement, and it ought at once to convince statesmen that the action pressed upon them is demanded on public grounds, and those almost exclusively. In short, the profession is not asking something for itself. It matters little or nothing to the existing body of practitioners, in any personal or pecuniary sense, whether the medical man of the next generation is improved, or where or on what terms their successors in practice obtain their licences. There will be just as many quacks and ill-qualified practitioners after this question has been settled as exist now. What we want is to secure that the officially licensed, and so to say hall-marked, shall be in *fact* what they call themselves. The public must ever remain free to indulge its privilege of being maltreated at pleasure, but the risk run should be incurred with a knowledge of the danger. The crying evil against which Dr. GLOVER and medical reformers generally inveigh is the wilful—we had almost said wanton—perpetuation of a state of things in which the legal definition of "surgeon" or "doctor" may imply anything from scientific learning to conspicuous ignorance of the science and art of healing. We protest in the name of common prudence and the interests of the public and personal safety against a state of the law which allows young men who are plucked by one set of examiners to go directly and pass before another, in some instances positively coming back and obtaining *ad eundem* a qualification for which they have been pronounced incompetent. Is this satisfactory to the public? Cannot Ministers understand that facts like these are conclusive in spite of the apathy of individual members of the profession to whom they address themselves, and who, having secured the respect of their own *clientèle* by personal talents, are either too busy or too careless to contend for a reform in which they have no immediate interest.

The point we desire to bring out—and we have a special reason for enforcing it—is that the present demand for medical reform is in no sense a selfish or class movement. The profession has very little, if anything, to gain by it. The public is generally interested in the issue raised, and the concern of the profession is based on a desire for the progress of science and the advantage of the general health. The skill at the disposal of the community *will* be greater if the law affecting medical education is recast so as to be compulsory instead of permissive. As Dr. GLOVER very forcibly puts the case, the opposition to reform evinced by the licensing bodies is not surprising; on the contrary, it "is natural, and *constitutes an argument in its favour*. Old corporations are not generally parties to their own reform. They cannot be expected to do so here, neither can the Medical Council, which is a conglomeration of old corporations." This is the gist of the matter. The Legislature made the mistake in 1858 of entrusting the reform of medical education and the readjustment of the licensing power of the several examining bodies to a Council which represents not the profession or the public, or professional or public interests, but the universities and corporations and their interests. It was inevitable that matters should go on precisely as they have proceeded, to stagnation. The resultant of the nineteen forces combined has been a force known as the *vis inertiæ*. A party of convicted offenders have been Royally commissioned to consider their own penalties for the offence of neglecting golden opportunities of serving the profession and the public. They have elaborately considered and reconsidered the question for more than twenty years, and they would like to pursue the inquiry indefinitely, assembling in solemn conclave, and wasting money and time as occasion offered until the crack of doom! Meanwhile the public safety is disregarded, and medical education does *not* improve. Medical reformers, of whom Dr. GLOVER is a fair specimen, are seeking to press this significant version of the facts on the attention of the Government and the Legislature, and on public opinion. It is the true version, and we trust it will be accepted. If a statesmanlike policy animates the party in power it must be sooner or later, and if the community could only see the facts as we see them it would be convinced that this is not a question which can be prudently postponed.

LAST week, in reply to a question by Dr. FARQUHARSON, Mr. TREVELYAN stated that the scheme for the reorganisation of the Naval Medical Department had been virtually settled, and that its promulgation was delayed only until some minor points had been arranged with the Treasury. His explanation, however, was characterised by that hazy vagueness which so often distinguishes official announcements. "Ever since 1854 it has been understood that the pay and position of Naval medical officers shall be 7 per cent. better than the pay and position of Army medical officers, in order to counterbalance the advantages of the two services," and on this principle the new scheme is to be based. We confess our inability to understand, and we doubt Mr. TREVELYAN'S power to explain, in what manner the 7 per cent. scale of improved position is to be estimated, and we also note an absence of any allusion to the other prominent grievances under which the Naval medical officers labour. There is nothing said of the introduction of a new grade corresponding to that of Brigade Surgeon in the Army, nor of the intention to give practical effect to the right of choice of cabins according to date of commission, and a suspicious silence is observed as to the five years' service in the rank of Deputy Inspector, before being eligible for promotion. The 7 per cent. higher pay than in the Army was, we believe, introduced, and probably is now continued, to compensate for the compulsory half-pay to which the officers are liable when ships are paid off. But, as we have before pointed out, this is far from an equitable mode of remedying the evil. Under such a system the fortunate medical officer who has friends at the Admiralty may get considerably more than his fair share of compensation, while the unlucky man who has no interest at headquarters may have the mortification not only of having to wait an undue time before being again brought on full pay, but of knowing that another is enjoying what was intended to counterbalance the inequalities of the service. If the proposed scheme be adopted, the only mode of preventing injustice would be to keep a strict roster for re-employment of the officers compulsorily placed on half-pay.

But Mr. TREVELYAN added that "successful candidates will receive full-pay as surgeons from the moment of entering the service." Here, again, is the usual vagueness. Does he mean that surgeons on probation at Netley are to receive full-pay instead of eight shillings a day, as the Army and Indian probationers? or may this be supposed to foreshadow the abolition of the grade of probationers for the Naval service, and of the course of instruction at Netley? If the former, we shall not be long before hearing of discontent in the military services at the unequal treatment, and the favour shown to Naval candidates placed at Netley under exactly the same conditions as themselves. If the latter, we can only say that the Admiralty are about to inflict a very serious injury upon the Naval service generally and upon the medical officers individually. The advantage to the sailors of having the medical officers, before they are called upon to take up their important duties, thoroughly trained in all matters relating to the preservation of health and efficiency and the prevention of disease, must be obvious to all who have any practical acquaintance with the subject. The young medical officer must either acquire this special knowledge at Netley, or gain it at the expense of the unfortunate fellows entrusted to his care, as was the case under the old system before the school at Netley was established. The withholding of this training will materially affect the efficiency of the medical officers during the earlier period of their service, thereby inflicting injustice on our sailors and expense on the country. We still feel it to be our duty to advise candidates to withhold their applications till the conditions of service are published, or they may not improbably find that they have sacrificed position, comfort, and self-respect for a mere increase of pay. Meanwhile, if Mr. Trevelyan has any doubts as to the value of the special instruction given at Netley, we would recommend him to study the evidence given on the subject before Lord Herbert's Commission, and to consider well the wise and humane views entertained by that distinguished statesman and philanthropist.

◆

The feeling of the medical profession in reference to the Dentists Act and the Dentists' Register, and especially in reference to the readiness with which the General Medical Council undertook the administration of the Act, has always been one of great humiliation and regret. As an illustration of this we may refer our readers to Mr. Cattlin's address in another column. That feeling will be intensified by the Report of the proceedings of the Council at its one day's sitting of Thursday, the 3rd inst. The Council, it will be seen, was entirely in the hands of the lawyers. In Mr. Simon's apt words, "they bowed unreservedly to legal opinion, but he hoped the resolution would be so framed as to show that the Council was simply acting mechanically in obedience to the law." This "bow to the law" is indeed unreserved. Let us see what were the doctrines bowed to so meekly and without an attempt at resistance by the distinguished gentlemen constituting the Medical Council. Our readers will remember the deluge of dentists, or professed dentists, which succeeded the passing of the Act. The number registered on August 1st, 1879, was 5289, double that which was contemplated by the gentlemen who so confidently undertook this piece of legislation. Of this number 483 had licences in dental surgery from British Medical Corporations! The great majority were admitted to the Register on Section C of Clause 6, which entitles to registration *any person who, at the passing of this Act, was bonâ fide engaged in the practice of dentistry or dental surgery, either separately or in conjunction with the practice of medicine, surgery, or pharmacy.* It was over the use and construction of this clause by the Council that such humble and mechanical "bows" had to be made by Mr. Simon and his colleagues at the late meeting. It is difficult to say whether the persons registered by the Council or the Council itself were in the greater flutter. The time of meeting was, of course, most inconvenient. The cost of meeting we know, on the authority of the Treasurer, will be four or five hundred pounds. But all this had to be disregarded to settle the great questions arising out of Section C of Clause 6, which the President said affected the accuracy of the Dentists' Register in over five hundred cases. What were these questions? For a full answer to this we must refer our readers to the Report of the meeting, contained in our present impression. We will only here say that they were vital to the respectability of the Register. They were of this kind: What constitutes practice *bonâ fide* as a dentist? Is a man justified in declaring that he is in *bonâ fide* practice as a dentist when, in reality, he is only acting as an assistant to one who is so? Is "pulling out" teeth alone, by the hundred in the year, enough to constitute practice *bonâ fide* as a dentist? Can a man be said to be in practice as a dentist whose primary business is that of hairdresser, his secondary business that of tobacconist, and his third function that of tooth-drawing? Can a man be said to be in practice as a dentist *separately* who practises it in association with such businesses as the above? Can a man be said to be in the practice of dentistry in conjunction with the practice of medicine, surgery, or pharmacy whose name is not to be found on the Medical Register, the Pharmaceutical Register, or the Register of Chemists and Druggists? Finally, is the Registrar acting wrongly in putting into the Register a column describing the calling in connexion with which an applicant said he was practising dentistry? These were great questions affecting the respect to be paid by the medical profession and by the public to the Dentists' Register. We regret to say that the answer given to them all by counsel was exactly the opposite of that which, we presume, the framers of the Dentists Act hoped and expected, and, worse still, that the Medical Council accepted with scarcely any demur the decision of counsel. Thus the Register is to remain unpurged. The Council have resolved to keep on the names of hundreds of persons which have been challenged by the "British Dental Association," and they have the appearance of accepting the doctrine that men are to be considered in practice as dentists who were essentially hairdressers, and in practice as chemists, in spite of not being on any legal register of chemists, and not even in business as chemists.

This is, indeed, a humiliating position for a great Council of Medical Education to have come to. It has revived the race of barber-surgeons, which we had thought extinct. Mr. Simon somewhat ingeniously, and with a dash of severity, threw the blame of all this on the promoters of the Dentists Act, who, he said, no doubt thought they were securing that the new race of dentists were to be men in *bonâ fide* practice first, either as dentists *separately*, or actually registered as dentists, in connexion with medicine, surgery, or pharmacy. But are Mr. Simon and Dr. Quain quite right in shifting the blame of all this carelessness on the promoters of the Dentists Act? Is it not a fact that the clauses under which the deluge has happened were taken from the Lord President's Bill? Is it not a fact that this was done at the suggestion of the Medical Council? and that the Medical Council gave to this great subject only a fragment of time, and in this fragment expressed its willingness to accept the Bill, containing the clauses, amongst others, which have worked to the production of such a loose and worthless Register. The Council may well bow, not only mechanically, but morally, under such a responsibility.

◆

Vaginitis exfoliativa, or exfoliation of the epithelial lining of the vagina, is not an affection frequently observed; yet several cases of it have been recorded, and in some of these it was associated with membranous dysmenorrhœa. In a paper in the current number of the *Archiv für Gynakologie* Dr. Cohnstein describes an interesting case of this disease which was associated with severe dysmenorrhœa, but apparently not of the membranous kind. The chief interest of the paper, however, lies not in this case, but in the part of it devoted to membranous dysmenorrhœa, and more especially in the attempt therein made to explain the etiology of this form of menstrual disorder. Like most disorders of which we possess little real knowledge, membranous dysmenorrhœa has been the occasion of much theorising, rather more theorising than observing—some of it baseless and purely fanciful, and some of it with a show of reason. The attempt made in the paper referred to is quite refreshing in these days, when attention is concentrated upon local changes and mechanism, for it looks for the cause of the disease, not in the uterus or ovaries themselves, but in the general conditions of the system. Indeed, the author maintains that membranous dysmenorrhœa is not the result of local changes but of general disease. In support of this view he brings forward, in the first place, reasons for not regarding membranous dysmenorrhœa as a local affection. They are:—1. In by far the greatest number of cases of metritis, chronic catarrh of the uterus, tumours, &c., there is no expulsion of membranes. 2. Women who present no discoverable change in the sexual organs suffer from membranous dysmenorrhœa. 3. Of sixty-two cases collected, the author finds general disorders three times more frequent than local disease. 4. Cases are known in which a decidua menstrualis has been extruded without suffering. Such cases indicate that a general cause brings about the condition, and dysmenorrhœa is often only incidental. 5. Local treatment of membranous dysmenorrhœa is usually not followed by any good result; sometimes it produces more evil than good. Having given the above reasons for regarding dysmenorrhœa membranacea as not the result of local change, the author proceeds to give his reasons for believing in a causal connexion between hysteria and the disorder, and they are the following:—1. The frequent coincidence of a slight degree of hysteria with nervous dysmenorrhœa. 2. Dysmenorrhœa membranacea is not rarely associated with hereditary troubles. 3. In the course of hysteria the most various anomalies of secretion and excretion occur. 4. The occasional complete disappearance of the membrane, and its return after longer or shorter intervals; such irregularity cannot be due to a disorder of the genital organs. 5. The vaginismus and the suffering lasting through or only coming on during the intermenstrual interval, without apparent disease of the sexual organs. 6. In sixty-two cases collected by the author, in twenty the expulsion of membranes was said to be due to a local cause, while in forty-two it was ascribed to general disorders—as hysteria, anæmia, chlorosis, chronic dysentery, &c. Heartily sympathising as we do with the author in his attempt to elucidate the etiology of membranous dysmenorrhœa by having recourse to a wider base than the sexual organs, yet we cannot help feeling that with two exceptions the two sets of reasons given—those against regarding the disease as of local, as well as those for regarding it as of general origin—have no bearing upon the question. They prove nothing. The two exceptions are:—1. Women who present no discernible change in the sexual organs suffer from membranous dysmenorrhœa. Had we been able to state that women who present no change suffer, the author's first position would be proved, but it is well known that our means of investigation can discover only very coarse changes, while many even of these elude our search. 2. Were it true that two-thirds of the cases are due to general conditions, the author's second position would be a just inference—that is, that membranous dysmenorrhœa is due to general conditions. But, as a matter of fact, the general conditions presented by two-thirds of the cases were not those now described as the causes of the affection. In some of them, it is true, they may have been so described, but by no means in all. So long as our knowledge of the physiology of the female sexual organs remains in a state of uncertainty and doubt, we cannot expect that the pathology of the same structures will be better understood. The investigation both of the physiology and pathology of these organs is surrounded with peculiar difficulties, and this may be excuse enough for some theorising upon them; but we feel sure that we cannot arrive at a correct pathology until we arrive at a correct physiology, and any theory of the pathology or etiology of the uterus and ovaries which does not start from physiology will prove true, if at all, by accident only. Here we think Dr. COHNSTEIN has erred, and consequently missed his mark. We think with him that dysmenorrhœa membranacea has in many instances at bottom a general condition for a cause, though we do not believe it to be hysteria; that condition produces dysmenorrhœa by organic changes in the uterus resulting from it, though these changes may elude our means of research.

THE announcement that the Metropolitan Asylums Board propose to increase by sixty the number of beds devoted to small-pox in the Fulham Hospital has produced great agitation among the inhabitants of South Kensington, Fulham, and Chelsea, in the immediate neighbourhood of the hospital. A movement is being rapidly organised with a view of appealing on the one hand to the Metropolitan Asylums Board to reconsider their decision, and on the other to the Local Government Board not to sanction the proposed increase. A public meeting is announced to be held at TATTERSALL'S on the 11th inst., with a view of protesting against the action of the Metropolitan Asylums Board in this matter, and of taking such further action as may be needed, other than the action above referred to, especially the bringing of the subject before the House of Commons at the earliest opportunity. So far as the opinions of the principal promoters of this movement have at present been expressed, it is not contemplated asking for more than a withdrawal of the decision of the Metropolitan Asylums Board to add to the number of small-pox beds in the Fulham Hospital. They do not propose at present to raise the question of the suitability of site of the hospital with regard to adjacent buildings, and so to add to the great difficulties which the Asylums Board have to contend in making sufficient provision for the isolation of cases with reference to the extending epidemic of small-pox. Whatever these difficulties may be, however, having regard to the believed spread of small-pox contagion from the Fulham hospital into the neighbourhood (it matters not to them how this extension may be explained), they view the contemptuous indifference of the Asylums Board to the interests and feelings of the inhabitants of that neighbourhood in proposing to increase the number of beds for small-pox in the hospital, as altogether scandalous on the part of an important public body. But they find it difficult to believe that the Local Government Board, when appealed to, will sanction the decision of the Metropolitan Asylums Board. And here we must confess the population living near to the hospital stand on firm ground. Is it possible that that Board can have so recently instituted an inquiry for the purpose of ascertaining the truthfulness of the reported extension of small-pox from the Fulham Hospital in the neighbouring houses, and, before the inquiry has been completed, can give assent to the increase of the number of small-pox patients in that hospital? Assuming, as we have now good reason for doing, that, as compared with neighbouring parts of the metropolis, a disproportionate number of small-pox cases have occurred in the vicinity of the Fulham Hospital—whether this disproportion arises from the diffusion of the contagion from the hospital through the atmosphere, as some think, or from the frequent passage and careless regulation of ambulances carrying small-pox cases through the district, also the influx of visitors to the hospital coming from districts infected with small-pox,—it must be obvious that in either case to increase the number of small-pox cases under treatment in the hospital will augment the danger of contagion to the population surrounding it. It is difficult to conceive that the Local Government Board will take upon itself so grave a responsibility and suffer the Metropolitan Asylums Board to perpetrate so hideous a blunder. Whatever the difficulties of that Board may be at this moment, they do not justify them in doing what may lead to serious local mischief. Other more innocent sources of escape from their difficulties doubtless are open to them. The time has come when these recurring agitations from the neighbourhood of the Board's small-pox hospitals can be appeased by the teachings of general experience. The Metropolitan Asylums Board and the Local Government Board have persistently refused during the last ten years to make such inquiry into the reported extension of disease from the Asylums Board small-pox hospitals as was required, and now they must suffer for their judicial blindness. Unfortunately, the ratepayers have to suffer with them in pocket and person, and we can only hope that the inquiry now, and at last, being made at Fulham for the Local Government Board by Dr. THORNE THORNE and Mr. W. H. POWER may be the beginning of somewhat wider and more rational views of hospital administration for infectious diseases among the metropolitan population than have hitherto characterised the operations of the Board. It will, however, be months before the report of the inspectors can appear!

◆

WE think too well of the Government to judge it by the gift of a Knighthood to a respected member of the medical profession, the elected head of the College of Physicians of London. A Liberal Government is not likely so to satisfy its sense of what is due, in the way of honour, to a liberal profession. The place of the medical profession in a high state of civilisation is not yet fully defined, and the deference which is its due, by every proper criterion that can be applied, has not yet been accorded to it. On the Continent the medical profession is rather a recommendation to political place and honour than otherwise. Here, hitherto, by statesmen it has been lightly esteemed. We shall not too curiously inquire how this has happened, or who hitherto has been to blame? But we will venture to say that with an unprecedentedly Liberal Government in power we confidently expect an unwonted liberal recognition of the claims to State honour of men who have saved life on a large scale, or who conspicuously represent a profession that has this for its great function.

It cannot be maintained that our statesmen hitherto have shown any adequate public sense of the value of life-saving. There is one member of the profession, now of more than European fame, who would be *fêted* in every capital where civilised men rule States. He began life in the Naval Service; thereafter he laid the basis of his future fame and usefulness in the broad ways of general practice. He saw a destructive disease destroying hundreds of lives every year. He undertook an operation for its relief, but the procedure was so formidable and bold, that the then recognised leaders of the profession denounced both him and it. Now the procedure is recognised and practised throughout the globe, and the introducer of it is correspondingly honoured. For the honour of the medical profession in England we are glad to say it now never loses an opportunity of according its own hearty reward. But where is the State recognition of such an achievement? One statesman at least, and he a distinguished ornament of the present Ministry, has studied the dimensions of this achievement, though even he can scarcely realise the obloquy and the difficulty through which success had to be attained. The present Lord Chancellor has spoken of the work we are alluding to "with admiration," as "one of the most splendid triumphs of modern surgical art and modern philanthropy, one of the greatest achievements of medicine or of surgery in any age." Of the workman the Lord Chancellor said, "he was as well deserving of the highest PUBLIC honour as any man living." At the time of the Lord Chancellor's speaking (1875) he estimated that Mr. SPENCER WELLS had, by his first 500 operations, added 10,000 years to the lives of European women." Since then his 500 cases have become 1000, and the general care and success of surgery throughout the world has been, it may safely be said, doubled. Surely the State would honour itself by honouring one of whom such a judge as the present Lord Chancellor could say such things. And there is no conceivable difficulty in the way, unless it be the want of precedent, which is the very reproach to wipe away which we look to the existing Ministry.

Past favours and honours have been well bestowed, but they have been too restricted both in character and number. It has looked too much as if only those who had rendered personal service to Her Majesty or her illustrious family were thought worthy of distinction. Her Majesty does not so restrict the gift of honours in the case of other professions, and it would be gross injustice to her to believe that she cannot appreciate a service to the race unless it takes a personal form. We will not believe that such is the rule by which she graciously dispenses her Royal meeds of praise. She has added to the glories, already great, of queenly reigns, and she would be unlikely indeed, under proper representation, to withhold honour from one of her own subjects who has done so much to diminish the disease and to add to the life and the happiness of women, and through them of the world.

If we have, for illustration, singled out one instance, it is not that there is only one which calls for liberal State recognition. There are many others—Simon, Lister, Brown-Séquard, and Andrew Clark—men who, by their labours, have extended the term of human life, restricted the bounds of epidemics, illuminated the mysterious processes of disease, or enlarged history by saving the lives of those who make it.

Annotations.

"Ne quid nimis."

SIR WILLIAM MUIR MUIR, K.C.B., M.D.

The near approach of the end of the term for which Sir William Muir Muir has held the office of Director-General of the Army Medical Department—a department greatly developed under his superintendence, and saved from many probable misadventures by his skilful guidance—has occasioned some not unnatural anxiety. We cannot but hope and anticipate that the present incumbent of the now very important Directorate will be retained at the head of the medical affairs of the Army for some time longer, in order that the work he has in hand may be matured, and the great inconvenience which his removal would entail may be avoided. The feeling of the profession is strongly in favour of Sir William Muir's continuance in office; and we trust the Secretary of State for War will find it practicable to gratify the desire expressed.

THE PUBLIC MEDICAL SERVICES.

The Examinations for Commissions in the Army, Navy, and Indian Medical Services commence on Monday next at Burlington House. For the Army Medical Department no less than 66 competitors have entered their names; the Indian Service is well represented with 40; while the Navy, in spite of Mr. Trevelyan's statement in the House of Commons that the incoming candidates will obtain the advantages of the new Warrant promised for the 1st April, musters only 8 candidates. It would seem that something more than a money attraction is requisite to make the Royal Navy popular with the young members of the medical profession.

TREATMENT OF PAIN BY MECHANICAL VIBRATIONS.

For some years past Dr. Mortimer Granville has been occupied with important researches upon the possibility of combating neuralgia by mechanical means. Proceeding largely upon theoretical considerations, he came to the conclusion that a series of interrupted mechanical shocks to a nerve would diminish its sensibility, and for that purpose invented a small instrument whereby a succession of rapid blows could be kept up upon the skin. Many physicians in London and Paris have seen and employed the apparatus, and spoken of it with approval; but Dr. Granville forbore to bring it under general notice until it had been thoroughly tested. He has paid the penalty of his patience, and the old story is repeated of the publication of an idea by another person by whom it was conceived long after the one who first thought of it, but who did not proclaim it to the world. In justice to himself Dr. Granville should forthwith point out how he arrived at the idea, and state his experience of its practical enforcement. Meanwhile it may be interesting to summarise the statements of M. Boudet de Paris, who writes on the subject in the current number of *Le Progrès Médical*. After alluding to Dr. Brown-Séquard's observation that chloroform applied over the skin of an animal produces general anæsthesia by its irritant action on the peripheral nerves, he points out that all irritants or revulsives may be placed in one category—such as actual cautery, hypodermic injections of water, application of metals, magnets, tuning-forks, electricity, vesicatories, sinapisms, compresses steeped in ether or chloroform, a motley group, but each intended for the same end—the relief of pain; they all operate by irritating the terminal twigs of sensory nerves. Vulpian long ago showed the good effect of the local application of chloroform; and Landouzy has recently pointed out the remarkable influence in controlling the cough of phthisis of hypodermic injections of water; whilst the cautery, acupuncture, and each of the forms of electricity are commonly applied to relieve pain. The action of metallic applications—metallo-therapy—of which we have heard so much in the last few years, was best explained on the theory of vibrations by Vigouroux, who proceeded to experiment upon the effect of sonorous vibrations, which he thought might have a direct mechanical effect upon the sensory nerves. By the aid of a large tuning-fork and sounding-board he caused hemianæsthesia to disappear, and provoked contractions in hysterical subjects at la Salpêtrière, as rapidly as with the magnet or electricity. The pains of an ataxic were subdued when his legs were brought under the influence of these sound-waves. M. Boudet de Paris then thought this might be applied locally over a nerve—the sonorous being changed to mechanical vibrations by means of a small button attached to the resonater, and applied over the nerve. He therefore contrived a small apparatus consisting of an electrically mounted tuning-fork, the vibrations of which were transmitted to a rod which could be easily applied over a nerve. In a healthy man this mechanical excitation produced rapid local analgesia, often anæsthesia, the maximum effect being produced by application over a nerve which could be compressed on a bony surface. When placed against the skull its walls vibrate in harmony with the tuning-fork, and a sensation of approaching vertigo, frequently followed by a desire for sleep, is produced. An attack of migraine can be cut short by the application. Neuralgia—especially of the fifth, where the nerves issue from bony canals—disappears after a few minutes' application of the instrument to the nerve at such points, but in the case of deeper-seated nerves, much protected by soft parts, it is more difficult to get good results. The writer suggests this treatment for the pains of ataxics and syphilitics; he thinks there is no limit to its applications, and suggests that perhaps cranial vibrations may induce cerebral and thus general anæsthesia. Its mechanical action is comprehensible, when we see how simple friction of the skin may soothe very acute pain. He does not regard the number of vibrations as important. This, however, is, we believe, a point on which Dr. Mortimer Granville lays the greatest stress.

WESTERN INFIRMARY, GLASGOW.

Some years ago Mr. John Freeland, a well-known citizen of Glasgow, died at Nice, and left the sum of £40,000 to the Glasgow Western Infirmary, to enable the directors to complete the original design of the building. As the hospital is erected in the "pavilion" style, the extension naturally took the form of additional arms. Twelve new wards, containing over 200 beds, have in this way been put at the disposal of the public, the new buildings having already been completed and in part made ready for occupation. The new wards have, of course, a general resemblance to the old ones, except in a few matters of detail, in which improvement has been suggested by experience. Thus in the wall-colouring, the old dull green has been replaced by a light cream-colour, picked out in squares, with a broad belting of rich brown. The heating and ventilation are all that could be desired. The wards are full of light; the end windows, in particular, come down to the floor—an arrangement which permits convalescent patients to enjoy the view from the balconies in fine weather. Connected with each ward is a smaller room, containing three beds for the treatment of special cases. At each landing a large open space is provided, which will serve as excellent recreation rooms for the patients. One of the most important of the improvements effected consists in the erection, behind the hospital, of a nurses' pavilion, containing apartments for fifty nurses. It stands apart from the main block, but communicates with it by a covered way. This arrangement enables the nurses to spend their spare time away from the scene of their labours. These additions almost double the accommodation provided by the Infirmary. Already about forty of the extra beds are occupied, and in a day or two twenty more will be ready. But the full number of beds cannot be made available just at present, as the institution's funds are low, and it is plain that an increase in the number of patients taken in means increased expenditure. Additional beds will be opened, however, as the directors feel themselves warranted. A portrait of Mr. Freeland has been painted by Mr. Jas. Macbeth, and is shortly to be placed in the new building.

THE CATGUT LIGATURE.

THE cases recorded by Mr. Treves and Mr. M'Carthy at the last meeting of the Medical and Chirurgical Society are sure to arrest attention, and form a very valuable addition to our knowledge of the effects of ligatures upon the coats of arteries themselves. It is well to ask at the outset whether the particular mode of dressing—Listerian—used in these cases, had any *special* bearing upon the changes in the coats of the arteries. It is true we often hear of wounds healing in accordance with the "antiseptic type," but there is an entire want of evidence to show that this is in any way different from the old-fashioned "healing by first intention;" and therefore the sooner the new term, so apt to convey a false impression, is abandoned the better. The question Mr. Treves raised was, whether healing by first intention is the best mode to secure the permanent closure of a ligatured vessel, or whether the inflammatory effusion attendant upon the process of granulation does not afford a necessary, or at least desirable support, to the weakened vessel, if, indeed, it does not take an active share in the union of its severed coats. Were this the case, the healing of a wounded artery would prove an exception to the general rule observed in every other tissue, where the results of primary union are better than of granulation, and it is controverted by the fact—we believe it to be more than an opinion—that undue disturbance of the artery in its sheath is liable to be attended with disastrous results, and that the more carefully, and with least injury of surrounding parts, the vessel is isolated and tied, the better the prospect of healing. We believe that the facts of these cases are best explained by a consideration of the peculiarities in the effects of the ligature upon the arteries. In Mr. M'Carthy's case there was clear microscopic evidence that none of the coats of the vessel had been divided, and in Mr. Treves' case there was an absence of proof that they had been severed, Mr. M'Carthy stating his opinion that they had not. Here then, surely, we have an adequate explanation of the sequel. If these coats were not divided there was nothing to excite the formation of a thrombus, nor was there a stimulus for an adequate cell proliferation or exudation of lymph to make the walls cohere. As Dr. Jones pointed out in his classic work, it is by wounding the artery that its obliteration is accomplished, and where there is no wound mere compression of the vessel will not suffice to cause its permanent closure. Thus these cases support the generally accepted doctrine of the action of the ligature, and are a proof that we cannot depart from our present practice of severing the two inner coats of an artery with impunity. If our view be correct, there is in these cases little that bears upon the discussion of the value of the catgut ligature, for the peculiar result was due to the mode of using the ligature rather than to the material of which it was composed. There is no evidence that the catgut softened sooner than is generally desired; indeed, the permanent constriction of the vessel points to an opposite conclusion. But this lesson we may with advantage draw from the facts, that the use of the catgut ligature does not introduce a *new mode* of obliterating arteries. Nature's action is the same as it always has been, the difference is in the ultimate destiny of the ligature and the constricted outer coat of the artery.

THE LATE THOMAS CARLYLE.

OF no human being may it more reverently be said, than of Thomas Carlyle—"He, being dead, yet speaketh." The man has passed away at a venerable age, but his work remains; the brain is stilled, but the thoughts it created mightily prevail. Though lacking the scientific spirit and not unfrequently in direct antagonism to the scientific method, Carlyle did nevertheless influence the character and modify the habits of several generations of scientific workers. He was, however, a moralist rather than a philosopher, and appealed more to the heart than to the head. Like his great prototype, Socrates, his chief endeavour was to acquire a knowledge of himself as the starting-point of all moral action, and as the surest means of affecting the thoughts of others. Truth, diligence, and duty were the virtues he ceaselessly inculcated; and he, more than any other Englishman of this century, has fostered in us a healthy hatred of shams of every kind. Honesty, he taught us, is the highest virtue, and work the noblest worship.

REGISTRATION OF INFECTIOUS DISEASES IN GERMANY.

WHILE the registration of infectious diseases in England seems as far off as it did ten years ago, although its necessity is increasingly felt by medical officers of health, there seems a great probability of its being adopted in Germany. The Imperial Sanitary Bureau is reported to be now engaged upon the organisation of a comprehensive plan for reporting and registering all cases of infectious and contagious diseases occurring throughout the empire. It is proposed that the sanitary and medical authorities of every district shall be provided with special post-cards, on which to make weekly reports to the Central Bureau, where all such reported cases are to be duly registered. Such a register would afford valuable information concerning the first appearance and progress of any epidemic. As an invaluable assistance to sanitary authorities in their efforts to control the prevalence and fatality of infectious diseases, a local register of such diseases is even more indispensable than such a central register as is proposed in the German Empire.

ADMINISTERING ALCOHOL TO CHILDREN.

WE believe it is not an uncommon custom in the country to administer spirit in various forms to infants and children. It is, we think, very objectionable, in the absence of medical advice, and little better than the administration of opium. Two cases of death, in one night, that of twin children, are before us, both dying suddenly at Tenby, without being seen by a doctor. They were only eight months old, and the mother's chief idea of treatment seems to have been beef-tea with brandy or sherry—very doubtful dietetics at eight months. Death from natural causes was the ready verdict, which we would slightly amend thus: Death from natural and unnatural causes. The kindness of the parents was not at fault so much as their intelligence. The medical man examined said he could not account for the death, but is afterwards reported as saying that teething was enough to explain death.

ABSCESS IN THE KNEE-JOINT.

THE cases of suppuration in the knee-joint cured by incision and free drainage shown by Mr. Edmund Owen and Dr. Alder Smith at the meeting of the Medical Society on Jan. 31st, are worthy of more than a passing notice. The completeness of the cure in at least three of the four cases is unimpeachable, and although by no means a novel fact in surgical practice, is yet so infrequently met with that it is not uncommon to hear the possibility of such an occurrence doubted. We venture to think that the pathological interest attaching to such results is greater even than the therapeutical, for it is a most striking and important fact that after the knee-joint has suppurated, the synovial cavity being distended with pus, the joint can so perfectly recover that full movement is painlessly accomplished, and the utility of the limb for support and progression not at all impaired. It is true that all the four cases were children—three of them quite young children—and the recuperative power of childhood, both local and general, is greater than that of later years in some respects. But the laws of pathology are the same at all ages, and the processes by which the recovery took place are not limited in their action to the earlier years of life. These histories are another evidence that the wonderful power of the *vis medicatrix naturæ* is but imperfectly understood, and that we are too prone to set a limit to it, which it can under certain circumstances overstep. Therapeutically, also, these cases are of great importance, but not quite in the way that was presented to the Medical Society. The therapeutical lesson they teach is surely that the free evacuation of pus from the knee-joint offers the best, if not the only, chance of recovery in such cases, for they show that where that is done perfect recovery may ensue, while all experience teaches that where that condition is not afforded no such result is ever obtained. It is noted that two of the patients were treated throughout as out-patients, and in none of them was Listerism employed, although Dr. Alder Smith stated that if called upon to treat a like case again he should certainly use Listerian precautions. The cases on this account do not afford any just ground for comparison with the results of Listerism; in all cases alike it is by natural powers that the healing is accomplished, powers which are not dependent upon the presence or absence of a germicide or antiseptic agent. All that any form of treatment can do is to bring about the conditions necessary for the normal working of these powers, and prevent the occurrence of certain accidents or interruptions in this natural process. The free incision and drainage in all cases alike fulfil the first purpose, and Mr. Lister contends that carbolic acid properly used does the second. Until the great mass of scientific evidence to show that septicæmia and its allies are the result of influences introduced into the body from without, and that these influences are closely similar to those producing fermentative and other changes outside the body, that can be studied in the laboratory, and there shown to be controlled and destroyed by carbolic acid and other germicides, can be rebutted, the narration of cases such as those we are alluding to cannot enable us to approach a determinate knowledge of the value of the alleged antiseptic treatment. Surely, it is true that, while a large majority of patients with open wounds and abscesses undergo healing in a more or less normal manner, a few of them fall victims to septic diseases, and demonstrate the danger to which all have been exposed. Mr. Lister asserts that these dangers can be averted by a scientific use of carbolic acid, and records of single cases which have recovered without the use of that agent do not controvert his proposition. Such cases show what nature unaided by germicides can accomplish; the evidence Mr. Lister brings is directed to prove that these results can be made uniform. Nevertheless, we would commend the study of these cases to some of Mr. Lister's followers who are more distinguished for zeal than knowledge, and who so constantly assure us that their results could not have been obtained under any other plan of treatment, as if the warding off of germs had added to the resources of nature in the healing art. It may safely be affirmed that antiseptic surgery has added nothing absolutely new in kind to the results of treatment; its highest aim is to make what has hitherto perhaps been considered the specially favourable if not exceptional course of a wound a constant event. Surely this is no detraction from the merit of the treatment! Injudicious friends of any cause are usually its most dangerous enemies, and we believe that few things have tended more to retard the reception of Listerism by the older members of the profession than the wild, exaggerated statements of some of its followers, which have been notoriously at variance with the teachings of a ripe experience.

ON TENDON-REFLEX.

AN interesting paper has been written by Dr. H. Senator on the physiological relations of the phenomenon known as tendon-reflex. A sharp blow on the tendon of the patella, when the legs are crossed, will cause the leg to be raised by the sudden contraction of the quadriceps extensor femoris, and a movement of the foot can be induced by a similar blow applied to the tendo Achillis. Tschirjew has shown that in the rabbit the centre for the reflex act in the patellar-reflex is situated between the fifth and sixth lumbar vertebræ, the afferent fibres proceeding from the tendon, and not, as Joffroy maintained, from the skin. These fibres run in the crural nerve, the division of which puts an end to the phenomenon. Senator corroborates Tschirjew's statement that division of the spinal cord opposite the fifth or sixth lumbar vertebra abolishes patellar tendon-reflex. He finds, further, that division of one lateral half of the spinal cord at this level abolishes the reflex on the corresponding side only. There is, therefore, no decussation of the nerve fibres. Division of the lateral column on one side produces the same effect. Division of the posterior cornua of the grey substance does not abolish the tendon-reflex. He concludes that in this part of the lumbar region both the sensory and motor fibres of the posterior extremities are exclusively contained in the lateral columns of the cord. It is remarkable that the patellar tendon-reflex can only be induced by one kind of stimulation—namely, mechanical shock or sudden extension by a blow. Neither electric, chemical, nor thermic stimuli have any effect. Nor has such stimulation as can be applied by pricking, cutting, or pressure. Senator discusses the views of Tschirjew in regard to its presence in health and disease, and appears to think that it is not always demonstrable in health, and not always absent in ataxy.

EXCISION OF THE STOMACH.

ON the 29th ultimo Professor Billroth of Vienna excised about six inches of the greater curvature of the stomach, including the pylorus, for infiltrating carcinoma. The patient was a woman aged forty-three, mother of eight living children, who was suddenly seized with grumous vomiting last October. Marked symptoms of cancer of the stomach and stenosis speedily followed. The operation was decided on in consequence of incessant and uncontrollable vomiting which threatened inanition. The operation lasted one hour and a half. There were extensive adhesions to the omentum and colon. Fifty silk sutures were used to unite the duodenum and the remaining portion of the stomach. On the 5th inst. (a week after the operation) the sutures were removed from the external wound, which had united without reaction. The patient was doing well, and was able to take coffee, tea, and other light nourishment. This is the second time the operation has been done. M. Péan did it in 1879, removing a carcinomatous pylorus. In that case catgut ligatures were employed. The patient died on the fourth day.

THE PIGMENTATION OF COMEDONES.

In Virchow's *Archiv* P. G. Unna has recorded some observations which he has made on the nature of the colouring matter of comedones. His results are entirely opposed to the view that the black specks so commonly seen on the face are the result of extraneous "dirt," forced into and obstructing the orifices of the sebaceous glands. He has found that the pigment exists partly in the form of free granules, and partly diffused in the horny cells at the upper part of the comedo; the free granules are also most numerous at the same part. The pigment is black, brown, or blue, and the granules vary much in size and in number in different specimens. The blue granules give many of the micro-chemical reactions of ultramarine. He explains that the blue colour of many comedones is due to the thin layer of pigmented matter seen by reflected light over a plug of fatty substance.

A case of suffocation during sleep from the fumes of incandescent coke, placed over coal in a fire bucket for the purpose of warming a bedroom, has occurred at Welby. The lethal influence of the fumes of burning charcoal in an unventilated room is generally recognised, but of the deleterious nature of the exhalations of coke under the same circumstances the public seem yet to require to be informed. The above fatal case may assist in affording the necessary enlightenment.

At a conference of the teachers of Anatomy and Operative Surgery, held on Wednesday evening, the 3rd inst., at the Middlesex Hospital, it was unanimously resolved "That a committee be appointed to make inquiries and to report to a future meeting, (1) in what respects the Anatomy Acts should be amended, and (2) how the supply of subjects can be increased under the provisions of the existing Acts.

Mr. Hamilton Labatt died at his residence, Fitzwilliam-street, Dublin, last week at an advanced age. Mr. Labatt was a graduate in Arts of the University of Dublin, a Fellow and ex-Member of Council of the Royal College of Surgeons in Ireland, and held the post for many years of medical officer to the South City Dispensary District.

At a late meeting of members of the Cahir Branch of the Land League, a resolution was adopted calling on the members of the dispensary committee in that district, where a vacancy for a medical officer had occurred, to elect a candidate who professed sympathy with the League, and oppose a candidate supposed to be the nominee of the landlord class.

Mr. Luther Holden, the late President of the Royal College of Surgeons, will deliver the biennial Oration in memory of John Hunter in the theatre of the College on Monday next, at three o'clock. The library will be closed on that and the following day.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Monmouth (*Rural*). — Area 82,977 acres; estimated population 26,088. Dr. Willis reports that "the health of the district during the past year (1880) has reached a most unusual standard and the death-rate of the whole (12·65 per 1000 population) is the most favourable yet attained. Again, of this death-rate he says that it is "probably the lowest death-rate in the kingdom for a population including in addition to the agricultural population, miners, colliers, quarrymen, and others in iron-works, tin-works, and brick-yards." Dr. Willis refers to an exceptionally good crop of potatoes and all vegetables during the past year as affecting favourably the health of the district, and draws attention to the connexion between a wet year (as 1880 was) and a healthy one. He describes in some detail the prevalence of fatal infectious disease in his district, but we must demur to his association of the appearance of scarlet fever at one farmhouse in June with the pumping out during a whole day of a well polluted with sewage close to the door, scarlet fever having occurred earlier in the year in the district. Dr. Willis notes measles imported into the district from both London and a distant part of Herefordshire. Nothing is said of the general sanitary condition of the district, but reference is made to a Board School of which the water-supply was unfit for the use of children. This is not the first instance by many in which the improper sanitary arrangements of schools have been referred to by medical officers of health.

Birmingham.—Dr. A. Hill's report on the health of this borough for the quarter ending Jan. 1st, 1881, shows a death-rate of 22·64, as compared with 27·08 for the corresponding quarter of 1879, and a birth-rate of 35·2, as compared with 39·4 for the autumn quarter of 1879. "This very considerable and satisfactory decrease in the death-rate, as compared with the fourth quarter of last year, is partly due, observes Dr. Hill, "to a large reduction in the mortality from zymotic diseases, and partly to a decline in the death-rate from local diseases generally, but more especially from diseases of the respiratory organs, in consequence, probably, of the mild weather which prevailed during December, in contrast with the severe cold of the last month of 1879."

Mexborough (*Urban*).—Estimated population 6300; inhabited houses 1326.—Death-rate 20·31 per 1000 population (as compared with 18·16 in 1879). Mr. Wm. Sykes reports the death-rate as unusually high, and "at least one very serious outbreak of enteric fever" occurred during the year. An immunity from fatal small-pox he attributes to the "extremely well vaccinated state of the districts," thanks to an energetic vaccination officer. The outbreak of enteric fever referred to was confined to a circumscribed locality and was found to have been connected with imperfect sewerage, much fæcal pollution of the atmosphere (from foul privies) and a contaminated water-supply. Good work appears to be done in this district, but when we read of privies constructed without drains, as if approved, it is evident that even the rudiments of privy construction have to be acquired.

THE DISPOSAL OF "DUST."

The movement on the part of several of the metropolitan sanitary authorities on the question of the "dust" disposal still continues. The City Commissioners of Sewers have been considering the report of a deputation sent to several northern towns to consider processes of disposal in use there, and it would seem probable that the process partly in use in Leeds will be adopted by the City—namely, the destruction of the accumulated refuse by fire—or rather the *reduction* of the refuse to a harmless and useful form by fire. The St. Pancras Vestry have also been considering the report of a deputation of its members and certain officers, including the vestry clerk, the chief surveyor, and the medical officer of health (Mr. Shirley F. Murphy), which has also visited several northern towns to study this question. The deputation has recommended :—"1, The vestry should decide whether the collection of dust should be in the hands of the vestry or the contractors, and your committee are of opinion that the collection should be in the hands of the vestry; 2, whether this is decided in the affimative or the negative, your committee should be authorised to prepare draft regulations for collection for the consideration of the vestry; 3, that if the contract system is to be continued, your committee should report on the modifications which are required in the present form of contract; 4, that whether the vestry decide upon doing their own work as dust collectors or not, the refuse should be partly or wholly burnt, and, therefore, your committee should be instructed to seek for a site for works, and that the vestry should offer a premium of £50 for the best scheme of disposing of refuse by fire, accompanied with plans and other details." This report gives reason to fear that the Vestry is still influenced more by considerations for the pecuniary interests of contractors than for the sanitary interests of the ratepayers and inhabitants generally. Let us hope, however, that recommendations 2 and 4 will meet with the approval of the vestry.

SMALL-POX IN THE METROPOLIS.

We have received the following circular from the Metropolitan Asylums Board:—

Metropolitan Asylums Board, 37, Norfolk-street, Strand,
London, Feb. 8th, 1881.

SMALL-POX.

DEAR SIR,—The managers at their meeting on Saturday last having had under consideration a report from the chairmen of the several hospital committees directing attention to the rapid spread of small-pox in the metropolis—no less than 330 acute cases of this disease having been received into the hospitals of the Board during the past fortnight—I was directed to state for the information of your —— that should the number of admissions continue at the present rate, all the accommodation the managers have or can provide (pending the decision of the House of Lords in the Hampstead Hospital case) will be exhausted in about three weeks, after which it will be necessary for the various sanitary authorities and Boards of Guardians to supplement the action of this Board by making provision for the accommodation of any additional cases of small-pox that may arise in their respective districts.

I am, dear Sir, yours faithfully,
To ——, Clerk to the ——. W. F. JEBB, Clerk.

THE VACCINATION ACT, 1867.

A voluminous Parliamentary Return has been published, moved for by Mr. Barran, showing the number of prosecutions in respect to England and Wales since the 1st day of January, 1875, to the 1st day of January, 1879, under the Vaccination Act, 1867, distinguishing (1) those who under section 29 have neglected to procure the vaccination of a child, and (2) those who under section 31 have disobeyed the order of a justice for the vaccination of a child, and how often prosecutions under this section were repeated for the same child; stating also the amount of penalty inflicted on conviction, whether imprisoned in case of default, and if discharged under section 31, and the grounds for that discharge. No attempt is made to summarise the facts given in the return under its separate headings, but it is left for each person to form his own summaries and deductions. There would appear to be very little uniformity in the mode of dealing with these cases by the magistrates in different districts.

COMBINATION OF SANITARY DISTRICTS.

We gather from the *North Wales Guardian* that the Local Government Board contemplates the combination of the rural sanitary districts of Curwen, Ruthin, St. Asaph, and Holywell with the urban sanitary districts of Abergele, Denbigh, Ruthin, and Llangollen, for the purpose of appointing a single medical officer of health. This project was under the consideration of the Rural Sanitary Authority of Ruthin at a recent meeting, Mr. Murray Browne, the general inspector of the Local Government Board for North Wales, being present; but the project met with much opposition, and in the end the subject was adjourned to the next meeting. The report of the proceedings in the local papers shows a very considerable amount of misapprehension on the position and duties of a medical officer of health and the object of the Local Government Board.

SUNDAY MILK.

At a recent meeting of the Greenwich District Board of Works it was moved and carried that the inspectors of nuisances should be instructed to take milk samples on Sundays. It would appear that the milk-dealer has been accustomed to have his own way in this district on that day, and one of the members of the Board expressed the opinion that it was as lawful to prevent children being served with milk-and-water on the Sunday as for any other good deed to be done on that day. It is probable that milk-dealers have been as quick to perceive their freedom from the restraining influence of the sanitary authority on a Sunday elsewhere than in Greenwich, and we commend the example of the Greenwich District Board to sanitary authorities generally.

At the recent meeting of the Yorkshire Association of Medical Officers of Health, at Wakefield, the President, Mr. S. W. North of York, asked the question, How long a patient recovering from infectious disease—small-pox or scarlet fever—should be detained in hospital before being allowed to go forth and mingle with healthy individuals? Mr. Butterfield, the medical officer of health for Bradford, in replying to this question, observed that he did not think "the usual six weeks" as at all sufficient. He had known cases last over eight weeks, and sometimes over three months. Obviously if periods of detention extending over even the least of these larger periods—viz., two months—have to be entertained by local authorities, other considerations than those of preventing the dissemination of infection will chiefly influence their action in the matter.

Colonel Bolton, the water examiner for the metropolis, in his report on the condition of the water delivered by the different metropolitan water companies in December last, says that the water in the Thames was indifferent in quality from the 1st to the 4th of December, when it improved, and remained good until the 15th, after which it became bad, and continued in that condition for the remainder of the month. The water in the river Lea was also generally bad during the greater part of the month. Professor Frankland states that the water taken from the Thames by the different companies, except the Grand Junction Company, was "efficiently filtered before delivery." The water distributed by the East London Company (including Thames water) was "slightly turbid through inefficient filtration."

A gentleman residing at Horsham has been summoned before the local magistrates for having failed to provide a proper supply of water to a "lodge" he had built upon his estate. He contended that a "lodge" was something different from a residence, and that there was water within a reasonable distance. The magistrates, however, inflicted a fine of 5*s.* with costs, but the defendant announced his intention to appeal.

It is noteworthy that the Paddington Vestry have successfully prosecuted the owners of certain barges for having moored their vessels for upwards of twelve hours, when laden with offensive matters, within 500 yards of inhabited dwellings. A fine of ten shillings, with costs, was inflicted in each case.

The "States" of Guernsey, it is reported, have repudiated the Burial Act by refusing to sanction its registration. The clergy, members of the "States," took an active part in speaking, as well as voting, against the Act.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Although the registered mortality last week showed a decline from the recent excess, it again exhibited some of the effects of the recent severe frost. In twenty of the largest English towns, estimated to contain in the middle of this year a population exceeding seven and a half millions of persons, 5891 births and 4092 deaths were registered last week. The births exceeded by 705, and the deaths by no less than 835, the average weekly numbers during last year. The deaths, however, showed a decline of 430 from the high number returned in the previous week. The annual death-rate in these twenty towns, which in the first four weeks of the year increased from 21·3 to 31·0, declined again last week to 28·0. During the five weeks of the current quarter, ending on Saturday last, the death-rate in these towns averaged 26·5 per 1000, against 26·0, the average rate in the corresponding periods of the five years 1876-80. The recent excess in the death-rate was remarkably small considering the late inclemency of the weather.

The deaths in the twenty towns referred to the principal zymotic diseases, which had been 390 and 373 in the two preceding weeks, further declined to 366 last week, and included 102 from whooping-cough, 70 from scarlet fever, 54 from small-pox, 49 from measles, and 41 from fever (principally enteric). The annual death-rate from the principal zymotic diseases averaged 2·5 per 1000 in the twenty towns, among which it ranged from 0·7 and 0·8 in Bristol and Leicester, to 3·6 and 3·9 in Norwich and Sunderland. Scarlet fever showed the largest proportional fatality in Norwich, Sunderland, and Oldham; while whooping-cough was most fatal in Leeds and Liverpool. The 20 deaths from diphtheria in the twenty towns included 12 in London, 3 in Bradford, 2 in Liverpool, and 2 in Birmingham. The death-rate from fever (principally enteric) was highest in Nottingham and Sunderland. Small-pox caused 58 more deaths in London and its suburbs, while no fatal case of this disease was registered in any of the nineteen large provincial towns. The number of small-pox patients under treatment in the Metropolitan Asylum Hospitals, which had steadily increased from 77 to 520 in the fourteen preceding weeks, further rose to 617 on Saturday last; this is a larger number than has been under treatment in these hospitals since June, 1878. The number of new cases of small-pox admitted to these hospitals, which had been 142 and 114 in the two previous weeks, rose last week to 234. The Highgate Small-pox Hospital contained 37 patients on Saturday last, against 27 and 30 at the end of the two preceding weeks; 30 new cases were admitted during the week.

The deaths referred to diseases of the respiratory organs in London, which had been 371, 617, and 702 in the three preceding weeks, declined last week, under the influence of higher temperature, to 606, but exceeded the corrected average number in the corresponding week of the last ten years by 52; 441 were referred to bronchitis and 97 to pneumonia. The annual death-rate from lung diseases (excluding phthisis) was equal to 8·5 per 1000 in London, while the rate from the same diseases was 11·1 in Salford and 14·3 in Liverpool.

In the twenty towns last week the causes of 118, or 2·9 per cent., of the deaths were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths did not exceed 1·8 per cent. in London, while it averaged 3·9 per cent. in the nineteen provincial towns. No uncertified deaths were registered last week in Portsmouth or Norwich, while their proportion was largest in Oldham and Sunderland.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate averaged 28·9 per 1000 last week, against 24·6, 31·1, and 34·7 in the three preceding weeks; this rate was 0·9 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 18·4 and 18·9 in Greenock and Edinburgh, to 33·9 and 35·1 in Glasgow and Perth. The deaths referred to the principal zymotic diseases in the eight towns, which had been 107 and 125 in the two previous weeks, declined to 94 last week, and was equal to an annual rate of 3·7 per 1000; in the twenty large English towns the rates from these diseases did not exceed 2·5. In the eight Scotch towns the zymotic death-rate last week ranged from 1·9 in Greenock and Perth, to 4·8 and 5·2 in Glasgow and Leith. The fatal cases of scarlet fever in the eight towns, which had been 28 and 27 in the two preceding weeks, further declined to 14 last week, of which 9 occurred in Glasgow, 3 in Edinburgh, and 2 in Leith. The 34 deaths from whooping-cough were within 3 of the high number in the previous week, and included 20 in Glasgow and 8 in Dundee. The 10 deaths referred to "fever," however, showed a decline of 15 from the number in the previous week; 5 were returned in Glasgow and 2 in Leith. Eight of the 9 deaths from measles, as well as 5 of the 10 from diphtheria, occurred in Glasgow. Diarrhœa fatality continues to exceed the average for the season. The deaths referred to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy), in the eight Scotch towns, declined last week to 261, from 307 and 348 in the two previous weeks. These 261 deaths from lung diseases were equal to an annual rate of 10·5 per 1000 of the population in the eight Scotch towns; the death-rate from the same diseases in London did not exceed 7·6. The greatest fatality of lung diseases in the Scotch towns occurred again last week in Glasgow, Paisley, and Perth.

HEALTH OF DUBLIN.

The rate of mortality in Dublin showed but a slight decline from the exceedingly high rates in recent weeks. The annual rate of mortality from all causes in the city, which had been equal to 35·1, 45·7, and 47·4, in the three preceding weeks, was 46·5 last week. During the first five weeks of the current quarter the death-rate in the city averaged 41·3 per 1000, against 25·8 in London, and 24·0 in Edinburgh. The 297 deaths in Dublin last week showed a decline of but 6 from the number in the previous week, and included 31, or rather more than 10 per cent., which were referred to the principal zymotic diseases, against 37 and 34 in the two previous weeks. These 31 zymotic deaths in Dublin last week included 17 which were referred to fever (typhus, enteric or typhoid, and simple continued), 6 to whooping-cough, 3 to scarlet fever, 3 to diphtheria, and one each to small-pox and diarrhœa. The annual death-rate from these zymotic diseases was equal to 4·9 per 1000 in Dublin last week, while it did not exceed 2·9 in London and 2·2 in Edinburgh. The deaths referred to fever in Dublin, which had been 17 and 15 in the two previous weeks, rose again to 17 last week; during the past five weeks the annual death-rate from fever has been equal to 2·19 per 1000, and nearly nine times as high as the average rate from the same cause in the twenty large English towns in the same period. The 6 deaths from whooping-cough in Dublin last week corresponded with the number in the previous week, while the fatal cases of scarlet fever showed a further decline. The deaths of infants showed an increase, while those of elderly persons were only four less than the exceptionally high number returned in the previous week.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE "HOWARD" PRIZE ESSAY ON ORIENTAL PLAGUE.

The one fact of interest about this essay on "Oriental Plague" is that it has been adjudged by the Council of the Statistical Society the "Howard Medal" for 1880 and a grant of £20. It is from this point of view alone the essay deserves consideration. The terms of the competition required that the disease should be treated of in its social, economical, political, and international relations. No disease during the past ten years has occupied a larger degree of public and, so to speak, international attention than Oriental plague; yet of this there is not the slightest intimation in the essay, and, in consequence, the various social, economical, political, and international questions which have so recently had to be considered in this country on the subject receive no notice, and it does not appear that either the essayist or the Council knew of their existence. "Frequent reference," it is said at the beginning of the essay, "has been made to many works treating of the plague, these being specified at the end of the essay." The works specified are twelve in number, and do not include the great report of the French Academy of Medicine or one of the numerous reports on plague since its appearance in Western Asia in 1853. Much of the essay is taken up by a so-called "historical sketch," the value of which may be surmised from the fact that outbreaks of "dancing mania" and "sweating sickness" are mingled promiscuously with outbreaks of Oriental plague. Howard's work as to plague is mixed up inextricably with his work as to prisons. The chapter on the "Conditions under which the Plague arises" is written without any reference to the recent important light which has been thrown on the subject. The illustrations of the social effects of plague are derived from the older historians, although we have had the opportunity of studying them in our own days. Then, as to accuracy of language. Plague, we are told, appeared in 1813 in Malta and Gozo, killing between 4000 and 5000 people. A few lines after we read that plague has not been seen in Malta for one hundred and thirty-seven years! Again we read: "Plato recognised the contagious power of ophthalmia, and so in the fourteenth century Pope Clement VI. shut himself up in his house, and was one of the few persons saved"—from ophthalmia? Still, again, we read: "There has been a total absence of genuine Oriental plague [in England since the latter end of the seventeenth century], notwithstanding the great increase of trade, by which it was supposed to be imported. The improved condition of our quarantine laws is surely inadequate to produce such immunity." "The immunity from the plague, which all civilised countries now enjoy, is unquestionably due more to the improved sanitary condition of our towns and villages than to enforced measures of quarantine." But again we read: "The history of the prevention of this malady [Oriental plague] is very instructive, because it shows how suitable measures, when energetically carried out, can succeed in so perfectly conquering the severest of epidemic diseases, that it no longer occurs except in half civilised countries. This extraordinary result has been accomplished by quarantine measures rigidly carried out." We leave it to our readers who delight in literary puzzles to endeavour to reconcile the earlier with the later sentences here quoted. But it is possible that the Council of the Statistical Society do not know that the quarantine scheme for the protection of Europe from the importation of plague from the Levant was not completed until 1838—that is to say, two years before the disease disappeared from Europe, and six years before it vanished from Egypt. We do not dwell upon the confusion in the essay of the medical inspection of shipping and the sanitary improvements of places with quarantine, except to infer that such confusion must equally obtain in the Council of the Statistical Society. The shade of Howard may well cry to be saved from his assumed friends, but what of the reputation of the Statistical Society?

MEDICAL CERTIFICATES FOR CHILDREN.

The following recommendation of the District Education Committee has been adopted by the Liverpool School Board: "That the board do authorise the Committee to make arrangements with such medical men as the committee may from time to time select for the issue of medical certificates in cases where, for their own satisfaction, the committee may require such evidence to be procured by parents who allege the sickness of children as the reason for their non-attendance at school; and to make a payment of sixpence for each certificate so required by the committee." It is proposed to ask the dispensary medical officers to undertake the duty above-named.

Intelligence has arrived in Liverpool within the last few days of a serious outbreak of small-pox at Bathurst, British Gambia; also that quarantine restrictions are again in force at Goree, Senegal, probably on account of the reappearance of yellow fever there.

THE SERVICES.

BENGAL MEDICAL ESTABLISHMENT.—To be Surgeon-Majors: Surgeons John MacGregor, George Hutcheson, M.D., and Edward Reginald Johnson.

Surgeon D. H. Cullimore, I.M.D., formerly Resident Surgeon, Mandalay, has retired from the Service, receiving the half-pay pension of his rank and length of service.

THE TRANSVAAL WAR.

The following medical officers have arrived in Natal from India with the reinforcements despatched from that country for service against the Boers:—Surgeon-Majors S. B. Roe, J. A. Scott, W. Cherry, W. Keir, H. Waghorn, J. Barker, and H. Cornish; Surgeons R. W. Mapleton, J. A. Gormley, A. Kirwan, L. B. Ward, and G. T. Langridge. Surgeon-Majors S. M. Parkinson and Fraser and Surgeon Lloyd are on duty at Standerton, and Surgeon S. Wallis is with the wounded of the 94th at Prætoria. Dr. Wallis was with the 94th at the massacre on the march between Lydenburgh and Prætoria, and was the only officer who escaped unhurt. The hospital at Newcastle has been enlarged to accommodate 120 sick and wounded, and will form the Base Field Hospital of Sir George Colley's force. Surgeon-Major Babington acts as Senior Medical Officer of the column now at Laing's Nek.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon Thos. Harvey to the *Monarch*, temporarily, in lieu of a surgeon; Staff-Surgeon W. Algeo to the *Woodlark;* Surgeons W. J. Christie, M.B., and M. V. Stace, to Haslar Hospital; Surgeons J. J. Dennis, M.D., and C. F. Wales, to Plymouth Hospital.

IMPERFECTIONS OF THE DENTISTS ACT.

Abstract of an Address delivered before the Association of Surgeons practising Dental Surgery on Jan. 26th, 1881.

BY W. A. N. CATTLIN, F.R.C.S., PRESIDENT.

AFTER some remarks on medical reform in general, Mr. Cattlin addressed himself to the question as it affects the dental profession in particular, and spoke as follows:—

I turn to the subject of dental politics with great reluctance. The dispute which is raging between the parties respecting the Dentists Act has not been conducted in a satisfactory manner.

In 1859 a charter was obtained by the Royal College of Surgeons of England, which enabled it to grant licences in dental surgery to candidates who were little better than half educated up to the standard of medical fitness required from its members. Thus was permanently introduced the questionable principle of authorising persons to practise an important branch of surgery who had only obtained a limited knowledge of the science. This bold step was undoubtedly an act of great injustice to every Fellow and Member of the College; yet they were in no way consulted in the matter. The only precedent I can find for granting a special degree in this country of late years is when the licence in midwifery was given by the English College of Surgeons to *three* persons who were not qualified practitioners; but the practice was immediately discontinued, and it has since been issued only to Members of the College. The dental licence has, however, been given to persons who are not members of the College for more than twenty years, and the practice is still continued. The Dentists Act goes still further than the charter, and extends the same evil to the Scotch and Irish colleges. It also encourages the mere "dentist" to assume the prefix of "surgeon," to the injury of those who have an exclusive right to the title. Finally, by establishing a separate register for dentists (which the public may easily mistake for the Medical Register) it completely divorces that branch of surgery from the whole science. These are the wrongs of which we, as members of the College, complain. The Dentists' Register is now crowded with ignorant pretenders, who are supposed to have made a false and fraudulent declaration, "that they were in practice as *bonâ fide* dentists when the Act became law;" but as there is no legal definition of the words *bonâ fide* dentist, I fear the General Medical Council will be unable to erase their names, and they will be a disgrace to the profession for a generation to come. There will be a meeting of the Medical Council shortly (at the cost of about £400) to consider what can be done to remedy this condition of things; but, unless they inquire into each particular case, and act upon the rules of common sense, I see no way out of the dilemma. The General Medical Council, under the circumstances, has power to expunge the names of impostors from the Dental Register, and their decision is final; but I fear they will be obliged to refer the matter to a court of law, and much time and money will probably be wasted before a legal decision can be obtained.

It has long been an established fact that a full knowledge of the science of medicine is absolutely necessary to the proper understanding and successful practice of any branch of surgery, and on that ground the Legislature requires its public officers to hold the double qualification. By this it will appear that the licensing of half-educated specialists is repugnant alike to the best interests of the public and to the medical profession at large. It also forms a bad precedent for future action.

My attention has been called by our secretary (Mr. Hamilton Craigie) to a short leader in THE LANCET of October 30th, 1880. It goes so much to the point that I will ask your permission to quote it *in extenso.* [Quotation given.]

A number of influential American dentists have formed the Oral Society of Boston, and no one is allowed to become a member of it who is not a qualified medical practitioner. They also hold that all special degrees in medicine should be abolished. This is a step in the right direction, and shows that the profession in the new country is becoming alive to the necessity of preventing its ranks from being overrun by a colony of mere specialists. In recognition of similar principles, which were initiated by this association, the Oral Society of Boston have invited your Secretary and President to become honorary members of it, to which they have assented, and I assure them we appreciate the compliment which has through you been paid to us.

It is simply idle to persuade any but the most prejudiced that a partial education is sufficient for the successful practice of any branch of medicine. A greater deception was never fostered by the mind of man, and yet the chief promoters of the Dentists Act have suffered themselves to be deluded by this false and ridiculous idea. The surprising effects which may result from even slight pressure or irritation of a very small branch of our complicated nervous system (producing serious disturbance in remote parts), can only be traced and understood by those who have a full and intelligent knowledge of its functions. The discoveries of Dr. Brown-Séquard have shown how necessary this knowledge is to the practice of dental surgery. What half-educated anatomist could trace the cause of deafness to irritation of the nerve of a tooth, unless he understood the great theory of reflex paralysis? and there are numerous complicated symptoms arising from diseased teeth (sometimes coupled with functional disturbance affecting the general health) which can only be skilfully treated by one who has a minute knowledge of all the resources of medical art.

Having answered the fallacious argument that the education of a surgeon is not necessary for a dentist, I will ask and answer the question, What difficulties are there to prevent a surgeon becoming a dentist, if he makes a special study of dental surgery after he has taken his diploma? I sincerely hope this practice will be adopted by young surgeons. It has been asserted that the time required to learn both dentistry and surgery would be too long, and that the hand can only be tutored in early youth to perform the delicate operations of dental surgery. This (so far as it is true) applies with equal force to delicate operations on the eye and other parts of the body, and yet there is no lack of skilful operators in every branch of surgery. Gold stopping is perhaps the only dental operation which requires considerable practice, but the necessity for the use of that particular metal has been greatly exaggerated. It is a fact, that has been proved by experiment, and is confirmed by experience, that only the few, however well taught, acquire the power of manipulation which is necessary to make a perfect gold filling in awkward positions within the mouth. Many large cavities in the molar teeth (if sufficient care be taken to prepare them) may be well filled by a person of ordinary skill with palladium amalgum, and some of the osteoplastic preparations are suited to the same operation in incisor and other front teeth. I do not desire to detract from the value of perfect gold stoppings, but I do say that only a few of the best dentists can make them perfect. It is trifling with common sense to deny that all the other operations in dental surgery can be well performed by the surgeon after a moderate term of experience. If further proof be required to contradict the false statement that proficiency in dentistry can only be acquired in early youth, let the honourable and brilliant career of such men as Bell, Craigie, Harrison, Arnold Rogers, and numerous others now living and equally skilful, who began to practise the specialty at mature age, proclaim the fallacy of such a doctrine. The truth is that mechanical talent is not uncommon; most men possess it, but in different degrees. Moreover, a delicate sense of touch (as contra-distinguished from what is called a heavy-handed person) belongs to the individual, and is generally born with him. It is a perfection of touch which is the gift of nature, and art cannot imitate it. On the other hand, a person who is peculiarly rough may improve in manipulation by experience, but he will never attain to the same degree of perfection as that to which I have alluded as the gift of nature.

Purposely omitting any reference to the mechanical branch of dentistry (which I think should be practised separately), let us seriously inquire what there is in the surgical branch which gives the slightest excuse for a special licence. Verily I believe the manner in which this document has been forced upon the public is as unjust as it is impolitic. It is a monstrous fact (that no longer should be tolerated) that before the student is allowed to pursue his studies at the Dental Hospital of London he is required to give a written undertaking that it is his intention to take out the dental licence.

Having arrived at this point, let us consider what the public duty of this Association is under the vexatious difficulties that lie before it. I think we should endeavour to convince our opponents that we hold our opinions solely because we believe them to be right. I am not one of those who think that an intelligent minority should, either from the love of popularity or the dread of defeat, go with the multitude to do evil; but it is always wise to show polite deference for the opinions of others. We should endeavour to obtain a just and reasonable compromise by the amendment of the Dentists Act, to the extent which I have indicated—namely, that no one but a qualified practitioner should be allowed in future to receive the dental licence, or use the title of "surgeon" alone or in conjunction with any other word or words, and that a clause to the same effect should also be inserted in the new Medical Amendment Bill; that the Dentists' Register should be purged and be made conspicuously dental; and that those who have been tempted to take the dental licence, thinking it to be a more honourable degree than it really is, should have the way made easy for them to acquire the diploma of member. I think this Association should show good feeling by helping them in every way. It is given to but few to possess so fine a judgment as will eneble them to perceive and correctly estimate the course of coming events in great and complicated matters, and to fewer still amid the din of strife and the force of rivalry so to direct their conduct that it shall tend only to the public good. "Bad as the world is, respect is always paid to virtue." Even our bitterest enemies will not dare to raise the treacherous voice of slander against us if we oppose them with generosity, and ever keep in mind the good old maxim, "To err is human, to forgive divine."

ARMY MEDICAL SCHOOL.

THE winter session of the Army Medical School at Netley terminated on Monday, the 7th inst., when, after the preliminary business of winding up the session had been concluded, the Right Hon. the Secretary of State for War, Mr. Childers, delivered an address to the assembled surgeon probationers and candidates for commissions in the different branches of the public service, and handed the prizes at the disposal of the Senate of the School to the successful competitors. Not only the benches of the lecture theatre, but every available portion of space in the area were occupied by officers and visitors, the latter including Mrs. Childers and a few ladies. Among the officers present were—General H.S.H. Prince Edward of Saxe-Weimar, commanding the Southern District, with Captain Lord A. Seymour, A.D.C.; Colonel Bray, Assistant Adjutant General, and Colonel the Hon. J. C. Dormer, Assistant Quartermaster General; the Director-General, A.M.D., Sir Wm. Muir Muir, K.C.B.; the Director-General of the Medical Department of the Royal Navy, Dr. Reid; Surgeon-General Sir J. Fayrer, K.C.S.I., Physician to the Council of India; Lieut.-General Sir J. M. Adye, K.C.B., Surveyor-General of the Ordnance; Colonel Sir C. Pearson, K.C.M.G., Commandant at Netley, with the military staff of the hospital; Surgeon-General D. R. Mackinnon, Principal Medical Officer, and the medical staff; Surgeon-General J. A. Woolfryes, C.B., C.M.G., Principal Medical Officer of the Southern District, with several medical officers from Portsmouth; Surgeon-General G. A. Shelton, M.D., Head of the Medical Branch in the Director-General's office at London; the Director-General of the Ordnance Survey of the United Kingdom, Col. A. C. Cooke, C.B., R.E.; Col. H. Burne, C.B., late Military Secretary to the Government of India; and various others. The candidates for commissions, one hundred in number, as they sat in their uniform presented the appearance of as fine a body of young men as could be seen anywhere in equal number.

After Mr. Childers had given his address, in which he chiefly referred to the importance of the duties which devolved on the medical departments of the public services in time of war, and in such climates as India, he requested the gentlemen who had gained the prizes to come forward, and to each in succession he made some kind and appropriate remarks. To Mr. G. M. J. Giles, M.B. Lond., of H.M.'s Indian Service, who had scored the high number of 5410 marks in the combined London and Netley examinations, Mr. Childers handed the Herbert prize and the Parkes Memorial bronze medal. The Herbert prize, which was founded in memory of Lord Herbert, to whose exertions the School mainly owes its existence, consists of a sum of £20, but no medal is attached to it. In handing the certificate for this award to Mr. Giles, the Secretary for War said, however, that he should ask Mr. Giles' acceptance of a medal, as a souvenir of the occasion, which he would personally present to him—an announcement which was received with much cheering. Mr. S. A. Crick, who heads the list of probationers of the British Service, received the Martin Memorial medal—a gold medal given at each session of the School to the gentleman who most distinguishes himself in the subject of tropical disease. This medal was established to commemorate the late Sir Ranald Martin, who not only took an active part with Lord Herbert in originating the School, but also subsequently, as a member of its senate, for many years exhibited a very active interest in its welfare. Another prize of an interesting origin, and specially given for the session of the School which has just passed, was carried off by Mr. J. Shearer, of H.M.'s Indian Service. It will be remembered by many that during the recent war in Afghanistan Lieutenant Maclaine, R.A., who was wounded in the battle of Maiwand, near Candahar, fell into the hands of the enemy, and after being kept a prisoner by them for several weeks, was cruelly murdered about the time when the troops under Sir F. Roberts defeated the force under Ayoob Khan. Among the papers of this unfortunate officer, which reached his family, was found a memorandum to the effect that, in consequence of his own sufferings from the want of surgical advice and attention, he felt a desire to do something for others, who might fall into the same need of surgical help, but who, unlike himself, might happily be within reach of it. Acting on this expressed wish, his family had set apart a certain sum, part of which—viz., £10—they offered as a prize, to stimulate attention to the subject of military surgery at the Army Medical School. There had been a keen, close race for this prize, and the result was so near that it was mentioned there was only a difference of twenty-five marks among the first six on the list of competitors. The marks gained by these gentlemen respectively in this competition were: J. Shearer, 775; J. R. Dodd, 770; S. G. Hamilton, 765; S. A. Crick, 763; A. R. Sedgefield, 760; and G. M. J. Giles, 750. Mr. Dodd stood second in the list, having only five marks less than Mr. Shearer, who won the prize. Mr. Childers handed this gentleman, who, it was stated, had trenched closely on all the other successful competitors, a handsomely-bound volume, the gift of Professor Longmore. After a few concluding remarks from Mr. Childers, the proceedings in the theatre, and the forty-first session of the Army Medical School, were brought to a close.

Mr. Childers, Prince Edward of Saxe-Weimar, and the officers and visitors who had been present in the lecture theatre, were subsequently entertained at luncheon in the spacious mess-room at the officers' quarters.

We publish on another page the lists of candidates for commissions in the various branches of the service, with the marks gained by them, who have just passed out of Netley.

MANCHESTER.

(*From our own Correspondent.*)

At the last monthly meeting of the Board of the Royal Infirmary, the Medical Superintendent reported that one of the wooden structures, which so long have been an eyesore to the citizens of Manchester, had been removed, having been purchased by the Corporation of Bury as a temporary hospital for the reception of small-pox cases; he further reported that since its removal the annoyance to patients from the noise of traffic in the adjacent streets had much increased, thus further demonstrating the importance of paving the thoroughfares round the hospital with wood or some other noiseless material, the present noise being very detrimental to the comfort and quietude of the patients. The "therapeutic advantages of quiet" have been very much overlooked by the Corporation of Manchester, for, with the exception of St. Mary's Hospital (in front of which institution one-half of the street is paved with wood), the hospitals in this city are much inconvenienced by the constant roar of traffic which ceaselessly beats round them. Two hospitals in the centre of the town, the Eye Hospital and the Throat and Consumption Hospital, are rendered specially noisy by the absence of wood pavement. The thin skin of asphalt which was laid down experimentally upon the granite setts having worn off and left matters as they were originally.

The recent appointment to Cheadle Convalescent Home has caused great dissatisfaction amongst the students of the Manchester School, and again brought to the front an old grievance, they, rightly or wrongly, alleging, that in all our hospitals an undue preference is exhibited towards men from a distance, every appointment worth having being filled by graduates of London, Edinburgh, and elsewhere, to the exclusion of Manchester students. This mistaken policy is not that of the Medical School, but of the lay Boards of Management who control the appointments at the various hospitals.

At the last meeting of the Manchester Medical Society, which was a large and interesting one, Dr. Lloyd Roberts showed an ovarian cyst of large size, said at one time to have contained five or six gallons of fluid; he made some interesting remarks upon the use of the drainage-tube in ovarian and other abdominal sections, attributing largely to their use the very favourable results now obtained. Mr. Hardie narrated the case of a patient who had a tooth-plate fixed in his œsophagus for five months, and which resisted all attempts at removal, though it could be caught by a coin-extractor. It was finally passed per anum, the patient having declined œsophagotomy. Dr. Simpson exhibited a patient the subject of an aortic aneurism, and whose life had doubtless been prolonged by repeated galvano-puncture of the tumour. Dr. Bury also detailed the case of a young child who suffered from intussusception, and where fluid injections, and injections of air, had failed to relieve.

The report has just reached me, and it is with the greatest pleasure that I give it currency, that Drs. Leech and Dreschfeld, respectively lecturers on Materia Medica and Pathology at Owens College, have been appointed Professors. This is a graceful and well-merited acknowledgment on the part of the Senatus of the sterling worth and high teaching powers of these two gentlemen.

IRISH MEDICAL ASSOCIATION.

The following resolutions were passed at a special meeting of the Council of this Association, held on Jan. 25th, 1881:—

1. That this Association, while reaffirming the resolutions of the Council adopted on the 27th July, 1880, as to the advantages of early notification of infectious disease, is of opinion that the proposal to compel the physician to make a formal written notification either to the Sanitary Authority or to the custodian of the patient, would, if carried into effect, be of doubtful advantage to the public and be oppressive upon the medical profession.

2. That this Association does not admit the principle that a physician should be required to apply to public uses the information obtained by him in his capacity of a private practitioner; and the Association furthermore apprehends that, if it be declared that the visit of a physician to a patient who may possibly be suffering from an infective disease shall be, of necessity, followed by the putting in motion of the Sanitary law with regard to the infected house, a great inducement will thereby be afforded to defer calling for the physician until the disease has acquired such intensity that it can no longer be concealed, and must be treated under great disadvantages.

3. That the Association cannot assent to the sacrifice of professional principles and medical interests, which the Bill now before Parliament involves, until the custodian of the patient has been made fully responsible, under penalties, both to ascertain from a medical practitioner the nature of the disease and to report the same to the Sanitary Authority; and until, after an effort made to enforce such responsibility with vigilance and firmness, it has been found to be impracticable to do so.

4. That, irrespective of the objectionable principles of the Bill already referred to, the proposals to pay to the physician one shilling for thirty days' notification of cases occurring in an infected house—to pay no fee whatever for such services in a public institution—to compel the physician to attend in court without fee to prove his certificate, if necessary, and to impose a penalty of £5 upon him for such omission to notify, are altogether unacceptable to the profession.

5. That, therefore, the Committee of this Association be instructed to take all necessary steps to cause the Bill to be modified in its passage through Parliament or to oppose its passing if necessary.

Correspondence.

"Audi alteram partem."

MR. LISTER'S ADDRESS.

To the Editor of THE LANCET.

SIR,—In the leading article which you have honoured me by devoting to my address to the Clinical Society on the catgut ligature you express a desire for further evidence as to the persistent strength of the new chromic gut after steeping in warm serum, the time during which I had tested it being little more than half an hour.

The serum which I employed for the purpose being derived from blood taken from a cow with antiseptic precautions, and being still perfectly sweet, I have made some further experiments, in accordance with your suggestion. I first tried the specimen of gut twelve years old, prepared by the old method, a portion of which I exhibited at the meeting steeped in serum. It is comparatively slender gut, having little more than half the thickness of the chromic gut with which I before experimented, the average diameter being 1⅔ hundredths of an inch. Two trials of it in the dry state gave 5 lb. 9 oz. as the average breaking strain,[1] and two other pieces, after steeping half an hour in the warm serum, broke at 3 lb. 14 oz. In other words, this especially well-seasoned sample of what the old method could provide was deprived by warm serum of about one-third of its strength in half an hour.

I next tested a piece of gut prepared three months ago by the new method, similar in thickness to the other—viz., having an average diameter of 1⅔ hundredths of an inch. Four trials with it in the dry state gave an average breaking strain of 6 lb. 15 oz. I then placed in the warm serum three other pieces of the same hank, after measuring their diameters. One of these pieces, with diameter 1⅔ hundredths of an inch, tested after it had been one hour in the serum, broke at a strain of 5 lb. 13 oz. Another piece, which when dry measured decidedly less in diameter than the first, was tried after being fourteen hours and a half in the serum, when it also broke at 5 lb. 13 oz. A third piece, just 1⅔ hundredths of an inch in diameter when dry, was left in the warm serum for twenty-four hours, at the end of which time it showed a breaking strain of 5 lb. 10½ oz. Thus the new gut continued as strong at the end of a day in the serum as it had been after the lapse of an hour, and lost in the serum only about one-seventh of its full strength in the dry state, a result corresponding very closely with that obtained in the former experiment with the thicker chromic gut after forty minutes' immersion. At the same time, the new gut being considerably stronger to start with than that prepared by the old method, its strength, after steeping for twenty-four hours in warm serum, was greater than that of the old kind in the dry state.

I felt pretty sure beforehand that the new gut would thus persistently retain its strength in the serum, because in numerous experiments which I had made as to its quality after immersion in that liquid, I had observed not only the holding power of a knot tied upon it, but also its consistence, and I had found it as firm after the lapse of two days as after a couple of hours. But in reality it is only for the tightening up of the knot that great strength of the catgut is required; and, having ascertained that the new gut was little impaired in resisting power by steeping in warm serum for as long a time as was ever likely to intervene between the passing of a thread by the surgeon and the tying of the knot, I felt I had all the evidence that I desired. For it has never happened, so far as I am aware, that a ligature of catgut, when once the knot has been secured, has proved treacherous in the way of rupture of the cord. When mishap has followed its use, it has been either from slipping of the knot, from premature softening and absorption of the substance of the catgut, or, last not least, from putrefaction having been allowed to take place in the wound.

I am not surprised you should have seen an apparent inconsistency in the idea that micrococci, which are harmless in ordinary wounds treated antiseptically, should have been the cause of the separation of the hempen ligatures by suppuration in the case of thyroid tumour. I may therefore, perhaps, be allowed to say in explanation that the difference in effect between the micrococci developing indefinitely in the interstices of the thick hempen threads and the same organisms on the surface of an organising blood-clot washed perpetually by serous discharge and occasionally by antiseptic lotions, seems analogous to the unhealthy ulceration occasioned by water-dressing left unchanged for several days, as compared with kindly healing under the same application daily renewed. The organisms present in the water-dressing are probably the same in both cases, but the longer duration of their fermentative agency gives rise to greater acridity of the products.

I am, Sir, yours obediently,
Feb. 8th, 1881. JOSEPH LISTER.

⁂ We are extremely glad that our remarks last week have been the means of eliciting from Mr. Lister the evidence which was certainly required to make the credentials of his new ligature unimpeachable. These results are such as to commend the thread very strongly to all surgeons. It is not desirable to mix up with this matter a discussion on the influence of micrococci upon the healing of wounds, but in reference to Mr. Lister's remarks on this point, we would merely state that the analogy he draws seems not quite parallel, and there is at least one other view of the matter to be taken. Does not the organising blood-clot, he refers to, by its own inherent vitality prevent the noxious development of these micrococci, while the secretions of a suppurating wound have no such power?—ED. L.

STATISTICS OF OVARIOTOMY.

To the Editor of THE LANCET.

SIR,—I hold that the statistics of all hospitals are public property; I know that this is the view of many of the most eminent members of the profession, and I believe that it is general. Hence I cannot admit any breach of professional etiquette in using the statistics of the hospital to which I am surgeon; neither can I admit that my use of them was in any sense "an incomplete and *ex parte* statement of results," for I gave the complete ovariotomy statistics of the Samaritan Hospital for the nine years from the beginning of 1872 to the end of 1880, both inclusive. Had I known that Dr. Bantock regarded hospital statistics as private property, I might have confined my remarks to my own cases only; but it is of importance to all those who are anxious to compare different modes of practice, that the actual results should be made known, so far as they can be accurately ascertained.

I am, Sir, yours truly,
J. KNOWSLEY THORNTON.
Park-street, W., Feb. 8th, 1881.

---

[1] It may be worth while to describe the manner in which the strength of the gut was tested in these experiments. A piece of steel of horseshoe form is suspended by a ring on the middle of its convexity, so that the horns of the horseshoe are dependent, these horns being perforated for the reception of a cylindrical bolt of steel, which thus lies horizontally, and can be removed at pleasure. A piece of the catgut having been tied in a double reef knot, the bolt is partially withdrawn and readjusted after the noose of the catgut has been slipped over it. Into the lower part of the catgut ring thus suspended is passed the upper end of a pot-hook, to the lower part of which are attached weights approaching what the catgut is likely to bear, and also an empty bag, into which shot is poured till the cord gives way. The shot is weighed, and the result, added to the other weights, gives double the breaking strain of the gut. For as the cylindrical bolt works with perfect smoothness in its bed, it adjusts itself so as to prevent inequality of strain in the two sides of the catgut ring, which thus take an exactly equal share in sustaining the weight.

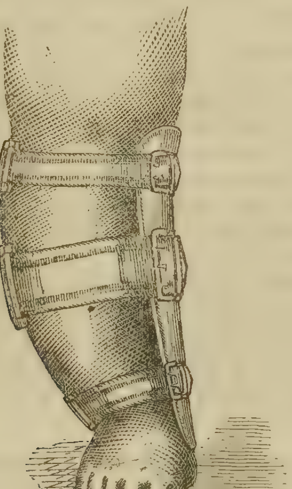
SPLINT FOR BOW-LEGS IN CHILDREN.

To the Editor of The Lancet.

Sir,—During twenty years' practice I have often found myself in a great difficulty with regard to treating the very common affection of bow-legs in young children, and especially in cases not depending on disease. I admit in starting that I have succeeded in straightening some with the leg-iron, but it is a cruel instrument to place on the leg of a child beginning to walk, owing to its weight being fully half a pound, together with the attached boot, which must of necessity be worn with it. Another drawback to it for general use is its great expense, which places it completely out of the reach of the majority. In fact, the leg-iron is only suitable for the different forms of talipes, but for want of a better appliance I have used it myself in cases of bow-legs, there being nothing beside it so far to be had except the common straight padded wooden splint, which is comparatively useless owing to the impossibility of keeping it in position unless the child be kept constantly lying, a resort to which would be out of the question in a healthy child of a year old, the proper time to interfere; besides, the common straight splint requires to be bandaged on, and if not done evenly must worry the little patient.

There is another great objection to those two appliances, their unsightly appearance, in itself enough to deter almost anyone from adopting them, even if the parents could be persuaded of their complete success, as they attract attention so much to the deformity. Very often, if you ask the parents, as their children are growing up with bow-legs, why they had not attended to them in infancy, the general answer is, "The doctor told us they would become straight as the child grew up." And why do the doctors say so? Simply because there is not an effectual light and cheap appliance to be had for the purpose.

The splint I wish briefly to bring before your notice, and of which I subjoin a woodcut, professes to remove those wants and disadvantages, as it combines lightness, cheapness, durability, easy application, together with sightliness and comfort to the child, the whole apparatus weighing little over two ounces, neither wood nor iron entering into its composition. It is adapted from the patent plastic felt, and for which there are already two patents, but neither of which has before been used for this purpose. When this material was first introduced to my notice I at once was struck with the idea of trying it for bow-legs. At first I applied it on the outside of the leg, making the bow part my fulcrum; but, from experience, found that did not suit; then I adapted it to the inside, making the fulcrum at the garter and ankle-joint, with the desired result.



In order to secure a perfect fit it is necessary to have it moulded to the leg in its soft condition, thus adapting itself closely to the parts, on which it is intended to press evenly, leaving the curve free. The top and bottom straps are merely for the purpose of keeping the splint in position, and the centre broad one to act on the curve with pressure as necessary. It covers the ankle-joint, to which it is moulded, slightly padded as well as at the top, and extends far enough below it to prevent the foot turning inwards, as it is generally inclined to do in those cases either with or without weak ankles, but not in the least impeding the action of the joint. As it is shaped to the calf, and extends more than half way around it, there is not the least fear of its changing position. This I have proved in several cases, and which I think one of its greatest advantages.

I have applied this splint in cases of rickety children, and with even more speedy success, as the bones adapt themselves with less pressure. It may be applied when the child is six months old, and, if the legs are not sufficiently straight, at twelve months. Shoes or light boots should be worn with it; but on no account to use strong leather boots with the idea of supporting the ankles.

Without encroaching too much on your space, I hope I have said sufficient to explain what I trust may be found a useful appliance in this very common deformity among children, and which I am confident requires only to be tried to prove its utility.—I am, Sir, &c.,

Oakley-street, Chelsea. H. Fisher, M.D.

"WOOLSORTERS' DISEASE."

To the Editor of The Lancet.

Sir,—Dr. Tibbits practically asks me to repeat in full detail, with drawings and specimens, my third and fourth Brown Lectures. In these lectures I dealt in detail with the points which he has raised, and subsequently demonstrated a large number of specimens, photographs, &c., on which the conclusions were based, and by which they are mainly sustained. I regret that in the nature of things it is impossible for me to repeat this in your columns. If, however, Dr. Tibbits will read the admirable abstracts furnished by your reporters, he will, I think, find many of his queries answered. For the rest, I trust that in my report on the pathology of the disease to be made to the medical officer of the Local Government Board he will find sufficient detail of evidence to satisfy him, and I shall always be happy to assist the Bradford Commission in any way in my power.

Yours faithfully,

Feb. 7th, 1881. W. S. Greenfield.

MEDICAL NOTES IN PARLIAMENT.

Noxious Gases.

In the House of Lords on Monday a Bill relating to Alkali Works was read a first time. The Marquis of Huntly said he proposed to take the second reading on the 15th inst.

Rivers Conservancy and Floods Prevention Bill.

On the motion of Earl Spencer the following Peers were nominated the Select Committee on this Bill:—Earl Spencer, the Duke of Somerset, the Duke of Bedford, the Duke of Marlborough, the Marquis of Huntly, the Earl of Derby, the Earl of Sandwich, the Earl of Jersey, the Earl of Camperdown, Viscount Bury, Lord Monson, Lord Penrhyn, and Lord Norton.

In the House of Commons on Thursday, February 3rd, the Burial and Registration Acts (Doubts Removal) Bill (Lords) was read a third time, and passed. The order for the second reading of the Medical Appointments Qualifications Bill was deferred for a week. The atmosphere in the House throughout this sitting was oppressively warm; and Sir G. Campbell gave notice of a question to the First Commissioner of Works on the subject.

On Friday a petition for inquiry into the East India Army Medical Department was presented from Arthur Barclay.

On Monday a petition was presented from John Picthall for redress in connexion with the Indian medical service. Returns were presented of correspondence and evidence relating to inquiries at Dromore and Belfast workhouses. In reply to Sir George Balfour and Mr. Pugh, the Marquis of Hartington said he hoped shortly to present to Parliament papers connected with the recent changes in the Indian Medical Department.

On Tuesday a return was moved for by Sir George Balfour on behalf of Mr. John Talbot, and ordered, of the number of all deaths in the metropolitan district in the year 1880 upon which a coroner's jury have returned a verdict of death from starvation or death accelerated by privation. The Universities (Scotland) Voting Bill passed through committee.

On Wednesday a further petition in connexion with the India Medical Department was presented from Nathaniel Hopkins. The second reading of the Coroners (Ireland) Bill was deferred for a week.

The Small-pox Epidemic.

Mr. J. G. Talbot asked the President of the Local Government Board whether he can inform the House as to the present condition of the epidemic of small-pox in the metropolis, and as to the available accommodation for small-pox cases in the hospitals which were under the control of the Local Government Board; and whether he would lay upon the table any communications which he had received from the managers of the Metropolitan Asylums District upon the subject? Mr. Dodson said the actual number of small-pox patients in the hospitals under the control of the Local Government Board was 700. Arrangements were being made by the managers, to whom great praise was due for their efforts, for increased accommodation, and 250 additional beds would be placed at their disposal. If it were not for the unfortunate proceedings pending in relation to the Hampstead Hospital case, 300 more beds would have been available for small-pox patients for that establishment. He had no objection to lay upon the table communications from the managers to the Local Government Board, and the replies of the Board thereto. Mr. W. M'Cullagh Torrens asked whether experience had shown that the aggregation of small-pox patients in the metropolitan asylums had frequently been attended with a serious outbreak of the disease in the surrounding houses; whether the number of deaths in the metropolis from small-pox since 1870 had not on the average been twice as numerous as in the previous eleven years; and whether any steps were about to be taken to provide more effectually than under the present system for the prevention and cure of the disease. Mr. Dodson said, it had been alleged that the residents of houses surrounding these hospitals had suffered from the small-pox, and he had directed an inquiry to be made as to the truth of the allegation. Until the inquiry had been made it would be premature for him to express an opinion on the point. In answer to the second question, he had to say that there was no doubt that the average number of deaths from small-pox in the interval since 1870 had been largely in excess of that in the previous eleven years, but that arose from the fact that the latter period includes the very exceptional year of 1871. The deaths since 1870 amounted to 15,533, of which 7878, or more than one-half, occurred in the following year of 1871. If, however, the twelve years of 1860-71 be compared with the nine years 1872-80 it would be found that in the latter period the average number of deaths was only 850, against 1425 in the former periods. As regarded the steps taken to prevent the spread of the disease, he had recently caused circulars to be addressed to the various sanitary authorities and Boards of Guardians, pointing out measures for adoption, with the view of securing vaccination and revaccination as far as practicable. He was glad to state that the local authorities generally had made a ready response to that appeal.

Obituary.

FLEET-SURGEON GEORGE HENRY DABBS.

MR. DABBS was a Fleet Surgeon in the Royal Navy at the time of his decease, which took place on Jan. 30th, at the age of seventy-nine. He was on the active list for over twenty years, serving on the West Indian station (in charge of the Jamaica-hill Hospital), in South America, and as one of the surgeons of the Legion which served under Sir De Lacy Evans in the Carlist war. Subsequently he became surgeon of the Convict Hulks at Woolwich, and while in this service did good work in the outbreak of cholera (of 1848?). While on duty at the hulks, Mr. Dabbs was assaulted by a prisoner with murderous intent, but recovered completely in all but the loss of his hearing, deafness becoming more and more confirmed as age crept on him. For many years, however, he did the whole of the duties, anaided, of the convict prison at Parkhurst, and was only superseded in the charge of the whole management of the prison rendering his supersession necessary. He lived subsequently, and practised a little, at Newport, Isle of Wight, removing latterly to Buckland, Hants, where he died. He was a man of a singularly mild, placid, and gentle nature; but with these combined futility of resource and boldness in action. His personal influence over prisoners was great, as was the esteem in which he was held by all who knew him. His affliction, which gave so much solitude to his life, never in the least interfered with the expression of his deep human sympathies, or with the free-handed if silent charity he even extended towards those who were in want, or those with whom he dffered in opinion.

Medical News.

BRITISH ARMY MEDICAL SERVICE. — The following is a list of Surgeons on probation who were successful at both the London and Netley examinations held in the present month. In the instances of these gentlemen the marks gained at Netley are not counted, and they retain the places taken by them in the competitive examination at London:—

	Marks.		Marks.
S. A. Crick	2510	L. W. Swabey	1610
J. R. Dodd	2240	R. Haselden	1605
A. J. Struthers	2230	R. E. Ricketts-Morse	1600
G. E. Twiss	2230	W. J. B. Lyons	1590
R. F. Adams	2225	W. Rowney	1590
C. G. D. Mosse	2135	T. J. R. Lucas	1565
A. B. Cottell	2075	C. J. Addison	1560
T. Archer	2035	A. G. Kay	1560
S. G. Hamilton	2035	W. W. Pope	1560

INDIAN MEDICAL SERVICE. — The following is a list of candidates for commissions as Surgeons who were successful at both the London and Netley examinations held on Feb. 7th. The marks given are the total number gained by them at both the London and Netley examinations:—

	Marks.		Marks.
*G. M. J. Giles	5410	F. S. Peck	3890
A. R. W. Sedgefield	5017	K. H. Mistri	3800
J. L. Vangeyzel	4953	W. Deane	3785
A. F. Ferguson	4540	P. De Conceiçao	3715
E. F. H. Dobson	4305	G. E. Fooks	3657
†J. Shearer	4275	K. C. Sanjana	3615
S. Hassan	4230	J. W. T. Anderson	3555
R. J. Polden	4135	H. M. Hakim	3552
H. C. Banerji	4070	J. A. Burton	3550
H. N. V. Harington	4007	F. J. Doyle	3520
S. C. Nandi	3920	M. J. Kelawala	3514
G. M. E. McKee	3918	P. H. W. Boon	3430
A. H. Pierson	3895	M. P. Kharegat	3280

* Gained the Herbert Prize and the Parkes Memorial Bronze Medal.
† Gained the Maclaine Prize in Military Surgery.

NAVY MEDICAL SERVICE. — The following is a list of candidates for commissions as Surgeons who were successful at both the London and Netley examinations held in the present month:—

	Marks.		Marks.
W. J. Christie	3630	G. F. Wales	3150
J. J. Dinnis	3390	M. V. Stace	3030

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Feb. 3rd:—

Dunlop, James Hay, Upper Norwood.
Gabe, John Bernard, Morriston, near Swansea.

The following gentleman also on the same day passed his Primary Professional Examination:—

Cranstone, William Lefevre, University College.

At the Arts Examination recently held the following gentleman passed in the Second Class:—

Wakeham, Charles Henry.

GUY'S HOSPITAL.—Sir Richard Cross has just been elected a Governor of this institution.

ROYAL COLLEGE OF SURGEONS.—The library of this institution will be closed this day (Saturday), Monday, and Tuesday.

IT is proposed to establish a Cottage Hospital at Southend, and a provisional committee has been formed for the purpose of collecting subscriptions.

THE collections on Sunday, the 30th ult., in the churches and chapels of Hastings and the neighbourhood on behalf of the local medical charities amounted, so far as at present ascertained, to £401 12*s.* 1*d.*

SUPERANNUATION ALLOWANCES.—The following Poor-law medical officers have received superannuation allowances: Mr. J. E. M. Williams, lately of the Blean Union, £50; Mr. Edward Bates, lately of the Cardiff Union, £30; Mr. T. Collingwood, lately of the Rochdale Union, £75.

AT the annual meeting of the subscribers to the City of London Truss Society, last week, it was stated that since the foundation of the institution in 1807, 369,515 patients had participated in its benefits. The income during the past year had been £4780, and the expenditure £4718.

CARDIFF MEDICAL SOCIETY.—At the annual meeting the following gentlemen were elected officers for the present year:—President: Dr. M. G. Evans, Vice-President: Dr. Thomas Wallace. Committee: Messrs. Hardyman, Campbell, Buist, and Treharne. Honorary Secretary and Treasurer: Mr. T. Garrett Horder.

VACCINATION GRANTS.—The following gentlemen have received the Government grant for efficient vaccination in their respective districts:—Mr. W. E. Baylie, of the Fourth District of the Blything Union. Mr. P. B. Stoney, public vaccinator for the Millom district of the Bootle Union (third time).

AT the annual meeting of subscribers to the Dewsbury and District General Infirmary it was stated that the project for erecting new buildings for the charity was making satisfactory progress. The amount in hand and promised has reached nearly £8000. It is expected that the work will have sufficiently advanced to allow of the corner-stone being laid in the coming spring.

ULSTER EYE, EAR, AND THROAT HOSPITAL.—During the past year the number of new patients treated amounted to 1949, which included 146 admitted to the wards of the hospital. Of the extern patients, 1295 paid a fee of one shilling, while 654 were treated without charge. The Managing Committee have also endeavoured to carry out the same principle in the intern department; some patients being admitted free; but the majority are paid for principally by the unions to which they are chargeable, and by these means a sum exceeding £200 has been obtained.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.—The thirty-third annual meeting of this Association was held at the Grosvenor Hotel on Friday, the 28th January, 1881. The report of the committee showed the growing prosperity of the Association, there now being 121 members. It was stated that the first annual dinner was held on the 25th ult., Dr. Simpson, President, in the chair. The attendance was large, and included visitors from Liverpool, Blackpool, Bolton, Oldham, &c. The following is a list of office-bearers for 1881:—President: Dr. John Roberts. Vice-Presidents: Drs. Henry Simpson and Thorburn, Messrs. Dacre Fox and R. B. Smart. Treasurer: Dr. Joseph Stone. Secretaries: Dr. A. Wahltuch and Mr. J. Broadbent. Committee: Drs. Addy, Ashby, Barlow, A. M. Edge, J. S. Fletcher, A. Emrys-Jones, Ledward, Mallett, Peatson, Pierce, Ward, and Mr. Cullingworth.

AT the Liverpool County Court a tradesman was fined £5 with costs for having used the title of "druggist," he not being registered. The action was brought under the Pharmacy Act by the Council of the Pharmaceutical Society.

PROFESSOR PARKER, F.R.S., commenced his annual course of lectures on the Structure of the Skeleton in the Sauropsida, in the theatre of the Royal College of Surgeons, on Wednesday the 2nd inst. The following is his programme of the nine lectures:—Lecture 1: The principal points in the Classification and Development of the Sauropsida. 2: Lizards. 3: Snakes. 4: Turtles. 5: Crocodiles. 6: Extinct Reptiles and Birds. 7: Struthious Birds. 8 and 9: Carinate Birds.

AT the sixth annual meeting of the Glasgow Association for the Relief of Incurables it was stated that since the formation of the Association in 1875 no fewer than 519 persons had enjoyed its life benefits. The income for maintenance purposes for 1880 was £3496, the expenditure £3570. This charity, being one of the few medical charities which do not rob medical men of their patients by providing gratuitous relief for those who do not require it, is worthy of the most hearty support.

HOSPITAL SUNDAY FUND.—On Monday afternoon a meeting of the Council of the Hospital Sunday Fund was held at the Mansion-house under the presidency of the Lord Mayor, M.P. A donation (the second) of £105 from the trustees of the late Mr. James Drew was announced. Sir E. H. Currie and Mr. R. B. Martin, M.P., were unanimously reappointed honorary secretaries, and Mr. Henry N. Custance secretary of the Fund. The General Purposes Committee and the Committee of Distribution were re-elected, and the meeting, which was simply formal, closed with a vote of thanks to the Lord Mayor for presiding.—A denominational analysis of the Metropolitan Hospital Sunday Fund, published by one of the religious journals, goes to show that of the £28,000 received at the Mansion House in 1880, nearly £22,000 was contributed by congregations of the Established Church, £500 by the Roman Catholics, £2000 by the Independents, and £1100 by the Baptists.

GLASGOW EYE INFIRMARY.—The fifty-seventh annual report of this institution states that in the year 1880 the number of cases dealt with was 9521, being 707 more than during the previous year. Of these, 4899 were dismissed cured by ordinary treatment, and 839 cured by operation; relieved by ordinary treatment 847; by operation 125; dismissed incurable 34. Thus it seems that no less than 85 per cent. of those passing through the institution had been completely cured either with or without operation, while 14 per cent. had been relieved, leaving barely one per cent. sent out as incurable. The financial position of the institution had also improved, an increase of income from every source being noted. This increase is specially noticeable in the artisans' subscriptions—a very pleasing fact, as it shows that the class for whose particular benefit the infirmary was established continues to appreciate its value.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest*

ABBOTT, C. E., M.R.C.S.E., L.K.Q.C.P.I., has been appointed Medical Officer of Health to the Braintree Union Rural Sanitary Authority, at a salary of £150 per annum, until December 25th, 1883.

BATTERHAM, J. W., M.R.C.S.E., has been appointed House-Physician to the Royal Hospital for Diseases of the Chest, City-road, vice W. H. Jessop, M.B., resigned.

BEALE, E. C., M.A., M.B., M.R.C.P., has been appointed a Physician to Out-patients at the Great Northern Hospital, vice Dr. Ormerod, resigned.

BLANDFORD, J. W., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Norton District of the Stockton Union, vice Murray, resigned.

BLUNT, T. P., F.C.S., has been reappointed Public Analyst for the County of Montgomery.

BOTT, H. S., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Manchester Royal Infirmary.

CADMAN, A. W., M.R.C.S.E., has been appointed House-Surgeon to the Manchester Royal Infirmary.

CARTER, D'ARCY B., M.R.C.S.E., L.R.C.P.Ed., has been appointed House-Surgeon to the Clayton Hospital and Wakefield General Dispensary.

CLARKE, W. B., F.R.C.S., Demonstrator of Anatomy at St. Bartholomew's Hospital, has been appointed Surgeon to the West London Hospital, Hammersmith.

DALE, F., M.B., L.R.C.P.L., M.R.C.S.E., has been appointed House-Surgeon to the Manchester Royal Infirmary.

DOWDING, A. W. W., M.B., M.S., L.R.C.P., M.R.C.S.E., has been appointed a Clinical Assistant at the London Hospital.

DUKE, A., M.D., M.R.C.S.E., has been appointed Honorary Medical Officer to the Folkestone Infirmary and Dispensary.

FROST, W. A., F.R.C.S., has been appointed Assistant Ophthalmic Surgeon to St. George's Hospital.

GRAY, J. A., M.A., M.D., M.R.C.P.Ed., has been appointed a Visiting Medical Officer to the Leith Hospital, Edinburgh, vice R. Macnair, M.D., resigned.

GRIMWOOD, H. C., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health to the Pontefract Urban Sanitary Authority, vice Atkinson, whose appointment has expired.

HARVEY, Mr. S., has been reappointed Public Analyst for the Borough of Sandwich.

HATCH, W. K., M.B., C.M., Surgeon, Bombay Army, has been appointed Professor of Pathology in the Grant Medical College, Bombay.

JACOBS, H. R., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Third District of the Brackley Union.

LITTLE, J., M.D., F.K.Q.C.P.I., L.R.C.S.I., has been appointed Consulting Physician to the Rotunda Hospital, Dublin.

PAYNE, H., L.R.C.P.Ed., M.R.C.S.E., has been appointed House-Physician to the Manchester Royal Infirmary.

PEDDIE, A., M.D., F.R.C.P.Ed., has been appointed Consulting Physician to the Edinburgh Dental Hospital, vice Sanders, resigned.

PICKFORD, J. K., L.R.C.P.L., M.R.C.S.E., has been appointed Assistant House-Surgeon to the Liverpool Dispensaries, vice Dr. J. E. Hiffernan, resigned.

RICHARDSON, C. S., L.K.Q.C.P.I., L.R.C.S.Ed., has been appointed Medical Officer for the Austrey District of the Tamworth Union.

STEELL, G., M.D., M.R.C.P.L., has been reappointed Resident Medical Officer to the Manchester Royal Infirmary.

STREET, A. F., M.A., M.B., M.R.C.S.E., has been appointed Junior Resident Medical Officer to the Hospital for Sick Children, Pendlebury, Manchester.

WATSON, F. S., M.R.C.S.E., L.S.A.L., has been appointed Resident Obstetrical Officer to Charing-cross Hospital, vice W. J. Clarke, resigned.

WILCOX, R. W., M.R.C.S.E., L.S.A.L., has been appointed Honorary Surgeon to the Buckinghamshire General Infirmary, vice R. Ceely, deceased.

WILKINGTON, G. H., M.R.C.S.E., has been appointed House-Surgeon to the Manchester Royal Infirmary.

Births, Marriages, and Deaths.

BIRTHS.

BUSHE.—On the 29th ult., at Lower Leeson-street, Dublin, the wife of Cecil J. L. Bushe, Esq., M.B., Army Medical Department, of a son.

MURRAY.—On the 22nd December, at Idlewild, Hongkong, the wife of Surgeon-Major Murray, Army Medical Department, of a son.

REID.—On the 30th ult., at 12, Bridge-avenue, Hammersmith, the wife of John Reid, M.D., of a son.

SUTCLIFFE.—On the 7th ult., at Burnley, Lancashire, the wife of Alfred Sutcliffe, F.R.C.S., of a daughter.

YOUNG.—On the 31st ult., at Rose-bank, Merton-road, Bootle, near Liverpool, the wife of T. Frederic Young, L.K.Q.C.P.I., M.R.C.S.E., of a daughter.

MARRIAGES.

HUTCHINSON—WOOD.—On the 20th ult., at Christ Church, High Harrogate, S. J. Hutchinson, M.R.C.S.E., of Brook-street, Grosvenor-square, to Jeannie, youngest daughter of G. Wood, Esq., of Grosvenor Villas, Harrogate.

NEALE—CARSTENS.—On the 29th December, 1880, at St. Andrew's, Port Nolloth, Namaqualand, by the Rev. C. E. Jones, John Edward Neale, Surgeon, eldest son of Dr. Richard Neale, of South Hampstead, London, N.W., to Ellen Marie, second daughter of Captain R. Carstens, of Port Nolloth. No cards. Foreign papers, please copy.

RENTOUL—ISHERWOOD.—On the 5th inst., at the Pro-Cathedral Church, Liverpool, Robert Reid Rentoul, M.D., M.R.C.S., of Ballymoney, County Antrim, to Laura Constance, elder daughter of the late R. R. Isherwood, Esq., of Guisnes Court, Essex.

SANDWELL—LLOYD.—On the 9th inst., at the Parish Church, Thurles, co. Tipperary, by the Rev. Canon Harley, M.A., assisted by the Rev. C. S. Cooke, Rector, Edward Sandwell, L.R.C.P. & M.R.C.S.E., of Charles-street, Soho-square, W., to Eliza, second daughter of C. H. Lloyd, Esq., J.P., of Lisheen Castle, Templemore, co. Tipperary, Ireland. No cards.

DEATHS.

AITCHISON.—On the 3rd inst., at 8, George-square, Edinburgh, George Aitchison, M.A., M.D., F.R.C.P.E.

CAHILL.—On the 6th inst., at 26, Albert-gate, Hyde-park, after a protracted illness, Thomas Cahill, M.D. R.I.P.

DONALD.—On the 4th inst., at his residence, Sydney-place, Bath, after a long and painful illness, John Donald, F.R.C.S.E., Deputy Inspector-General of Military Hospitals, and formerly of Her Majesty's 24th Regiment.

HAYDEN.—On the 2nd inst., at Frogmore House, High Wycombe, William Henry Hayden, M.R.C.S.E., aged 68.

OLDHAM.—On the 5th inst., at West Hartlepool, R. Oldham, F.R.C.S.E.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, Feb. 14.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

ROYAL INSTITUTION.—3 P.M. Mr. Francis Hueffer, "On the Troubadours."

MEDICAL SOCIETY OF LONDON.—8½ P.M. Dr. Gilbart Smith will exhibit a Specimen of Stricture of the Œsophagus due to Malignant Disease.—Mr. Royes Bell will show a Case of Atrophy of Testicle following a Blow.—Mr. J. C. Wordsworth, "On Defects of Sight said to be due to Railway Accidents."—Dr. J. Milner Fothergill, "On the Prospects of Cases of Valvular Disease of the Heart."

Tuesday, Feb. 15.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Edward A. Schäfer, "On the Blood."

PATHOLOGICAL SOCIETY OF LONDON.—8½ P.M. The following specimens will be shown:—Series of Specimens of Tubercular Disease of Joints; Specimens of Synovial Tuberculosis; Abscess of the Liver; Congenital Truncation of Forearm; Unilateral Hypertrophy of Head and Face; Tumour of Spinal Cord; Degeneration of the Breast; Sacral Tumour containing Fœtal Structures; Congenital Sacral Tumour (card); Cystic Disease of Kidneys and Liver.

Wednesday, Feb. 16.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.—7.45 P.M. Council Meeting.—8½ P.M. Mr. T. Edgelow, "On Casual Communications."

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — 4 P.M. Professor W. K. Parker, "On the Structure of the Skeleton in the Sauropsida."

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND SCIENCES.—Mr. Sedley Taylor, "On the Participation of Labour in the Profits of Enterprise."

Thursday, Feb. 17.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Pauer, "On Drawing-room Music."

HARVEIAN SOCIETY.—8½ P.M. Dr. Woakes, "On Cases of Laryngeal Disease."—Dr. Cheadle, "On the Treatment of Empyema."

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC. — 5 P.M. Dr. J. Hughlings Jackson, "On Clinical Varieties of Hemiplegia."

Friday, Feb. 18.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — 4 P.M. Professor W. K. Parker, "On the Structure of the Skeleton in the Sauropsida."

ROYAL INSTITUTION.—8 P.M. Sir John Lubbock, "On Fruits and Seeds."

Saturday, Feb. 19.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Mr. R. S. Poole, "On Ancient Egypt."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE REGISTRAR-GENERAL AND MEDICAL OFFICERS OF HEALTH.

A MEDICAL OFFICER OF HEALTH informs us that he recently applied to the Registrar-General asking to be supplied with information for use in the compilation of his annual report, and was refused on the ground that, owing to the number of such applications, he (the Registrar-General) finds it impossible to supply such information by letter in anticipation of the publication of his official returns. Bearing in mind that there are now about 1600 sanitary districts, and nearly as many medical officers of health in England and Wales, we cannot agree with our correspondent that this decision is unreasonable. We have turned to the Registrar-General's Quarterly Return, published last week, and find the information required by our correspondent. The birth-rate in England and Wales during 1880 was equal to 34·6, and the death-rate to 20·7 per 1000 of the estimated population.

A Constant Reader.—1. It depends wholly upon the action of the guardians, but we should think not.—2. We should suppose that the retention of the one appointment would militate against the superannuation allowance of the other.

Dr. H. M. Thompson.—Our correspondent is referred to Child's "Essays on Physiological Subjects" and to Ribot on "Heredity."

W. C. H. (Liverpool).—We are not aware that any observations have been made on this subject.

THE MORRIS FUND.

To the Editor of THE LANCET.

SIR,—Will you do me the favour to acknowledge in your next issue the receipt of the following sums on behalf of Mrs. Morris, for whom an appeal was made in your journal of the 5th inst. :—

A Surgeon, London, £5; Dr. and Mrs. Tuckwell, Oxford, £3 3s.; A. Steadman, Esq., Great Bookham, £1; W. Y. Martin, Esq., Walkden, 6s.

I am, Sir, yours very truly,

Ewell, Surrey, Feb. 9th, 1881. GEO. R. BARNES, M.D.

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—Allow me just to mention, in reply to Dr. R. Neale's strictures in THE LANCET of Saturday last, that in the case of Mrs. C—— (which I recorded in the issue of January 22nd) the strychnine and iron mixture was not prescribed until she had been taking the Chian turpentine for fully three weeks. The improvement commenced within one week of the turpentine treatment, and was very marked, "the sleep and appetite returned, and the pain vanished." I simply ordered the strychnine and iron as nervine tonic and blood restorer, but relied chiefly on the Chian turpentine all through the case.

It is only a supposition on Dr. Neale's part that pain ceased because some sensitive nerves were destroyed or pressure removed by the breaking down of the mass. All I can say is that the poor woman began to get relief when she commenced the turpentine treatment, which, in my estimation, was more than a mere "coincidence," and fully persuaded me that we have in Chian turpentine a therapeutic agent of some power in at least giving great relief in the sufferings of cancer.

I am, Sir, yours truly,

H. A. ALLBUTT, M.R.C.P.E., &c.

Park-square, Leeds, Feb. 7th, 1881.

Mr. Oswald Orton.—There is no London agency for Hartnack's microscopes. Our correspondent must write to Messrs. Hartnack and A. Prazmowski, 1, Rue Bonaparte, Paris.

Dr. Byrom Bramwell's letter is, owing to its length, unavoidably held over till next week.

ANIMAL LIGATURES.

DR. J. L. NEILSON, of the Brooklyn Naval Hospital, contributes to the *New York Medical Record* the following historical note extracted from a southern professional journal dated September, 1847 :—

"Dr. W. S. Wragge, in a paper on the use of animal ligatures, states that he has been in the habit of using these ligatures for upwards of ten years, and for several years he has used none but these. In the course of this period he has tied the arteries of the fingers, hand, forearm, arm, leg, and thigh, and he has never seen any symptom result from which he could infer that the knot had not been removed by absorption. From the facts he has observed he deduces the following inferences : 1st, that the deer-sinew ligature, if properly applied, will effectually arrest hæmorrhage from vessels even of large size ; 2nd, that they produce less inflammation of the living tissues with which they are placed in contact, during the time they remain as foreign bodies in these tissues, than other substances ; 3rd, that they are susceptible of being absorbed and carried away by the action of the living parts in the midst of which they are placed."

DESQUAMATION AFTER SCARLET FEVER (?)

To the Editor of THE LANCET.

SIR,—My son is at a large public school near London. He was to have returned home for his Christmas holidays on the 20th of Dec. last, but on the 19th of Dec. I received a letter from the head-master, saying that on the previous day (Dec. 18th) he was found to be suffering from scarlatina, and, very properly, had been placed in the infirmary attached to the school, and of course could not be removed. I proceeded to the school at once, and saw the medical gentleman attending him, who informed me that the attack was unusually light, that there was an entire absence of fever, and that it was with the greatest possible difficulty he could detect any eruption. To my surprise I received a certificate from his medical attendant on Dec. 29th, stating "that my son might be permitted to join his friends on Saturday, the 8th of January, without the slightest risk to anyone." Notwithstanding this very decided opinion I followed the advice of medical friends, and, considering that the 8th of January was only three weeks from the date of the attack, and the other members of my household never having had this fever, I removed him to the seaside, and placed him suitably. On the 26th of January he was to have returned to school, and on the 24th, being at the same place where he was staying, in consequence of some representations made by the matron of the house he was in, I requested a very experienced and conscientious medical gentleman to inspect him and report to me his condition. Having done so, he told me he was actually peeling, and, of course, in an infectious state, and he confined him to the house, and forbad my daughter or myself to come in contact with him. Having communicated this to the head-master as an excuse for his not returning to school, he replied that he wished for my medical man's name, as he, not unnaturally, wished for his own sake to know the facts of the case.

You would much oblige me if you would publish the three letters which have passed between these medical gentlemen, of course omitting names and addresses, as I should be glad to learn from the general opinion of the faculty whether under any circumstances a person could be pronounced safe from disseminating scarlet fever infection three weeks after first being attacked, and more especially when no desquamation of the cuticle had taken place, before he was pronounced to be safe; and whether Mr. W—— had any justification for saying that the undoubted desquamation which took place six weeks after the boy was first attacked "was not the result of the scarlatina for which he had been under treatment." I enclose my name and address for your private satisfaction, and I remain, Sir, your obedient servant,

Feb. 5th, 1881. ENQUIRER.

[COPY.]

DEAR SIR,—Six weeks ago a pupil at —— College, of the name of ——, showed symptoms of scarlatina. The usual precautions were taken by me as medical officer of the college, and in due time the boy was permitted to return home after thorough disinfection. Having been informed that you have seen the lad within the last few days, and that you pronounce him to be still in an infectious state, I write to ask you if such is really stated by you, or whether, as I believe, there is not some misunderstanding respecting your opinion.

I am, dear Sir, yours very faithfully,

January 29th, 1881. ——.

DEAR SIR,—On the 24th of January I was requested by Mr. —— to call and see his son, who was said to be showing symptoms of desquamation. I had not seen him previously, and finding that such was undoubtedly the case, I recommended that he should be isolated, as well as kept indoors during the cold weather which has been prevalent.

I am, dear Sir, yours faithfully,

February 1st, 1881. ——.

DEAR SIR,—Thanks for your letter respecting young ——. I must be allowed to say, however, that when the lad left here, after three weeks' isolation (which began six weeks before you saw him), there were no signs whatever of desquamation of the cuticle. I must, therefore, give it as my opinion that, whatever may be visible now is not the result of the scarlatina for which he was under treatment here. I repeat that there was an entire absence of "fever" in the case—indeed, so mild was it that it was only owing to the great vigilance of our matron that it was brought under notice. The boy never suffered in the least, and it was with much difficulty I could detect any eruption.

I remain, dear Sir, yours faithfully,

February 2nd, 1881. ——.

EXPOSURE OF PERSONS SUFFERING FROM INFECTIOUS DISORDERS.

WE take the following from the *Local Government Chronicle*:—

"'Subscriber' writes:—'A domestic servant, aged fifteen, convalescent from scarlatina, but still in the infectious stage (as can be proved by two medical men who saw her after her arrival home), is sent a journey of over fifty miles by rail. Her removal was sanctioned by her employer's medical man, who had attended the girl. She was sent by her mistress, in charge of her mother, who was willing to take her. Will you advise your opinion—1. Was the exposure "wilful," after the medical man in attendance had sanctioned her removal as "safe"? 2. By whom should proceedings be instituted—the sanitary authority in whose district the station from which she started is situated, or that of the district to which she came; or by the railway company? 3. Against whom should proceedings be taken?'

"*Answer.*—We do not consider that in such a case a conviction under section 126 of the Public Health Act could or should be obtained. The case contemplated by that section is that of a person who, whilst knowing that he is suffering from a disease which is dangerous and infectious, exposes himself without proper precautions against spreading the disorder. Upon whom was the person, in the case referred to, to rely as to whether she could properly expose herself during the journey, if it was not the medical man who attended her during her illness? We can see no reason why the patient or any other person should be prosecuted for acting in good faith on the view of the medical man that her removal was 'safe,' which would necessarily mean, having regard to the disease from which she had been suffering, safe as regards the public as well as herself."

"BOOTS."

To the Editor of THE LANCET.

SIR,—In a very useful annotation on the subject headed "Boots" you call attention to the necessity of specially protecting the feet from the inclemency of the late severe weather, and recommend not only that boots should be of superior make and finish, but urge that the soles should be protected by hobnails and the uppers by dubbing. To a vast majority the former would be inapplicable, to few less so than to medical men, who would find hobnails, as a rule, very inconvenient, but who have often to sit for hours in a cold room after having trudged through the inclement weather; and it is because you are either unaware or have overlooked the claims of one material well adapted to meet the views you advocate that I call your attention to the fact, that, in my opinion at least, for such a purpose nothing answers all purposes better than vulcanite. This material I used for upwards of twelve months, and am doing so still, and can speak most highly as to its protective qualities. It is light and elastic, and wears better than leather. It was first introduced in the shape of a complete sole, but after being patented was found difficult to attach *it* to an upper, in consequence of which the patentee failed, when the stock was bought up by a few firms, one of whom was Saunders of Eastbourne, who used the material to clamp the soles of boots with, and as such I have used them for the period specified. If its merits were advocated it could be made to cover the whole sole, instep, &c., by having a thin part to cover the instep and heel; over the latter part a leather heel could be fastened, and this would keep it entirely in its place. Nothing is more pleasant to walk on, and it makes very little noise in going up an uncarpeted stair. As to dubbing, nothing answers better as protection to uppers than a composition of linseed oil, Barbadoes tar, and beeswax, well rubbed in over-night. It not only protects the uppers against the absorption of damp, as well as preserves the stitches when well rubbed into the seams, but is effective even in protecting from sea water. Having for many years spent my holiday in the hobby of marine zoology, I had one pair of boots for many years which for a month yearly were daily immersed in the sea water, and for which I used the above preparation. At last they came to grief by fire, not water. Pray consider the claim of vulcanite, &c., and endeavour to procure us another supply. It is a great boon to country doctors.

I am, Sir, yours obediently,
Feb. 2nd, 1881. GEO. MUNDIE.

To the Editor of THE LANCET.

SIR,—Allow me to supplement your very seasonable and sensible remarks on "Boots" by a hint how to make the "absorbent sole" non-absorbent. Having worn a new or newly-soled pair of boots for a few days to wear off the smooth surface of the leather, let them be perfectly dried, and every particle of dirt removed. Then with a small brush paint the sole and round the edges and seams with a good coating of common oak varnish; place them before a fire for a few minutes until the varnish dries in; repeat the process until the leather will absorb no more, and in a few hours they will be ready for wear.

If any of your readers will try the above plan they will be amply repaid for the very little trouble and expense. The soles will wear nearly as long again, and will not become soft or spongy, however long they may be worn, in snow or mud. I am, Sir, yours faithfully,
Feb. 4th, 1881. J. B.

Mr. R. F. Stockdale (Baltimore).—We do not prescribe.

Medicus.—The phenomenon is a common one in cases of partial loss of sexual power, and probably depends on the increased action of the spinal reflex centres during sleep, which are only weakened, not "destroyed." It has no diagnostic or prognostic significance.

D. F.—Any qualified medical practitioner would advise in the case.

BACTERIA IN THE CHOROID.

To the Editor of THE LANCET.

SIR,—This interesting discovery, which forms the subject of an annotation in your issue of 29th ult., lends support, and is my excuse for referring to an observation and suggested explanation which I submitted to your readers in a short note on "Muscæ Volitantes" (THE LANCET, May 4th, 1878). After some remarks on "the familiar riband-and-medallion-like form," I invited attention to "a distinct variety of muscæ suggestive of the presence of animalcules in the fluids of the eye, which I become conscious of when gazing steadily at a moderately bright patch of blue sky or homogeneous grey cloud. It consists of numerous minute shining points in unceasing choreic movement." I would now add that my eyesight has always been of the best; that I can at any time see these muscæ under favourable conditions of light, which must be daylight, and not such as to induce any sense of retinal fatigue, and that the character of their movements has confirmed me in my belief that they are microscopic organisms inhabiting the vitreous humour.

I do not grudge them the use of my globes, but trust none of their congeners will invade my cochleæ and semicircular canals, for though an admirer of the dance, I am no lover of dance-music.

I am, Sir, your obedient servant,
Islington, Feb. 6th, 1881. WM. MCLAURIN.

A Junior.—Announcement is only proper in the case of a provident dispensary, duly organised, and managed by a committee. The rules of the Northampton Dispensary are perhaps the best.

Mr. Jas. Wm. Smith (Doncaster).—Yes.

Inquirens.—The use of the title on such qualifications is misleading and indefensible.

FOREIGN BODY IN THE INTESTINES.

To the Editor of THE LANCET.

SIR,—The following case may prove of some professional interest:—W. G——, a soldier's son, aged ten years, had a fall last September, and in the effort to recover himself swallowed a pin which he happened to have in his mouth. He appears to have forgotten the circumstance soon afterwards, and continued in good health until the 23rd of January following, when he came under treatment for slight tenesmus and pain on defecation, symptoms which were relieved by a dose of castor oil. On the 27th he thought he felt a bone in the lower bowel, and an examination then revealed a sharp-pointed black pin, about 1¼ inch long, which had passed through the rectum, and was piercing the skin half an inch to the right of the anus.

Two days after the removal of the pin the parts were healed and the lad well—in fact, with the exception of the slight symptoms above mentioned, he suffered no apparent inconvenience from the four months' passage of the pin through his alimentary canal.

I am, Sir, yours truly,
Devonport, Feb. 4th, 1881. HENRY O'BRIEN, M.B.,
Surgeon-Major, A.M.D.

"MULTIPLE LIVER ABSCESS IN CONNEXION WITH DYSENTERY."

To the Editor of THE LANCET.

SIR,—In THE LANCET of January 8th, 1881, an interesting case of multiple liver abscess is communicated by Dr. Henderson of Shanghai. He concludes his instructive remarks by saying that he believes that Dr. Macleod and himself were the first to apply antiseptic precautions to the surgical treatment of liver abscess.

In the *Practitioner* for October, 1876, will be found a record of the antiseptic treatment of liver abscess, which Dr. Henderson has evidently not seen. I believe the date to be correct, but cannot verify it, as I am at present travelling in the south of Spain. At the same time I do not think that the matter of priority in this operation is of much importance, seeing that we are only humble travellers in the path pointed out to us by Prof. Lister.

I am, Sir, your obedient servant,
J. DICKSON HUNTER, M.D. Edin.
Malaga, Spain, Feb. 2nd, 1881.

"FOREIGN BODY IN THE EAR."

To the Editor of THE LANCET.

SIR,—Dr. White's cockroach in the ear reminds me of a child's ear stuffed with maggots, brought to me in my practice in Australia. Probe or forceps were no use, as they eluded the grasp, so I merely dropped into the ear a little spirits of turpentine, when the vermin wriggled out as fast as their contortions would enable them. They swim comfortably in prussic acid, but a drop of chloroform kills them immediately. I am, Sir, yours truly,
Feb. 5th, 1881. ALMER.

Dr. Francis E. Carey.—We could not go into details without having the other side of the question before us. There are ample rules, written and unwritten, for the guidance of partners and other medical men.

Dr. Wynn Williams' paper will be published in an early number.

Mr. H. J. Jones.—We must decline to take part in the discussion.

Appetitus rationi pareat.—We cannot say that a public appointment should be so regarded.

CHLORAL IN LABOUR.

A Subscriber, M.D., desires to be informed of the way and doses of giving hydrate of chloral in labour.

W. B. Roué, M.B., M.S.—The announcement appeared in THE LANCET of Jan. 29th.

Mr. B. Bell may refer to THE LANCET of June 7th, 1879, for information on the point.

TRACTION IN JOINT DISEASE.

To the Editor of THE LANCET.

SIR,—If you think the following case, from its apparent rare occurrence and its other surroundings, worthy a place in your columns, it is at your service:—

In 1878 a young gentleman (then in his fifteenth year) came home from school for his Midsummer holidays with a slight lameness referred to the right leg. The opinion and advice of one of the most eminent consulting surgeons in the metropolis were promptly sought, and the case was pronounced by him to be "scrofulous disease of the hip-joint." The prognosis unfavourable. The treatment recommended was perfect rest and a weight of seven pounds appended to the ankle by means of a cord passing over a pulley attached to the foot of the bed. It is not necessary I should enter into details concerning the progress of the disease from the above date to the present further than that it promises to end as favourably as could be hoped, with a shortening of the limb to the extent of little less than two inches. About two months ago, however, I discovered (quite by accident) that there was free motion in the upper part of the tibia, just below the knee-joint, and on a more close examination I discovered that it arose from a separation of the tibia from its epiphysis. Under the circumstances the first and most important thing to do, as it occurred to me, was to remove the weight, which obviously appeared to me to have been the sole cause of the mischief, and to treat the case in other respects as one of common or simple fracture. But from the uncertainty as to the length of time this condition might have existed, I felt doubtful as to the issue, and hence thought that, in addition to the other means adopted, it might be advisable to apply friction to the separated parts. This, however, in view of the patient's diathesis, I did not think proper or prudent to adopt on my own responsibility, and, with the sanction of the father, I went to London, and reported the complication to the same eminent gentleman who had been consulted before. On my stating the case to him, he appeared somewhat astonished, and, as it seemed to me, incredulous as to the possibility of such an event taking place, except, as he added, from disease or injury, and said emphatically that in a practice of forty years, "he had never seen such a case, that he had never heard of such a case, nor had he ever read of such a case." He also denied as emphatically that the action of the weight could have had anything to do in the case. From this, however, with due deference to so high an authority, I must beg leave to differ, and for the following reasons:—First, then, it appears obvious to me that the almost continuous traction exercised by such an appendage to the leg must (in a constitution such as the patient's) sooner or later have the effect of elongating the lateral ligaments of the knee-joint, and hence it would follow either that the bones constituting the joint must be separated or the tibia from the epiphysis. So far I grant that the former would be the more likely to happen, but the strong anterior crucial ligament within the joint already in a state of tension from the extended position of the limb would at once be in the best condition to offer resistance to a separation at the joint. It is evident, then, if anything yielded to the traction, it must be the union between the epiphysis and the tibia, as it did in this case unquestionably. The very rare occurrence of such a case, as exemplified in the remarks of the gentleman to whom I have alluded, gives it some interest, and must be my excuse for troubling you with it. In conclusion, I am rejoiced to be able to report that union has taken place between the separated parts, and that all is going on well.

I am, Sir, yours faithfully,

Jan. 1881. M.R.C.S., &c.

STOCKWELL SMALL-POX HOSPITAL.

THE statement respecting the spread of contagion from this hospital, referred to in THE LANCET of the 29th ult., was made in the course of the trial of the Hampstead Hospital case before Baron Pollock.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Byrom Bramwell, Edinburgh; Professor Longmore, Netley; Mr. O. Orton; Mr. Redmond, Gateshead; Dr. M. Duncan, London; Dr. Playfair, London; Dr. Duffey, Dublin; Mr. Judge, London; Dr. Macnaughton Jones, Cork; Mr. W. H. Smith, Birmingham; Dr. Lownds, Egham; Dr. Fentem, Bakewell; Dr. Morris, Cabul; Dr. Sweeting, London; Messrs. Worth and Co.; Mr. Stockdale, Baltimore; Dr. B. Fenwick, London; Dr. Mundie, Hessle; Dr. Dunkley, Balham; Mr. Karkeek, Torquay; Mr. Soper, London; Mr. McLaurin, London; Mr. Sutton, Sittingbourne; Mr. J. Williams, Brentford; Mr. J. Startin, London; Dr. Carey, Guernsey; Mr. Hill, Tottenham; Surgeon-Major H. O'Brien, Devonport; Mr. H. I. Jones, Scranton, Pa.; Dr. Hunter, Malaga; Mr. Berry, Wigan; Mr. Jalland, York; Mr. J. W. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.

The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

A Lecture
ON THE
SHOULDER-GIRDLE AND ITS MOVEMENTS.

By JOHN CLELAND, M.D., F.R.S.,
PROFESSOR OF ANATOMY IN THE UNIVERSITY OF GLASGOW.

THE shoulder-girdle in mammals is by no means so fully developed as in the majority of other vertebrates. The scapula is the only element of it which is constantly well developed. While the suprascapula is represented, if at all, by nothing more than a cartilage or epiphysis, the coracoid is reduced to a mere process of the scapula, save only in the monotremata; and the clavicle, although well developed in some widely separate forms, is sometimes absent altogether, and sometimes represented by a mere vestigial nodule. I have expressed a doubt as to the morphological correspondence of the cartilage or epiphysis of the vertebral border of the scapula with the suprascapula, partly from recollecting a curiously deformed human fœtus added about twenty years ago to the anatomical museum of the University of Edinburgh, in which the scapulæ were united to the spines of the cervical vertebræ by a pair of elongated bones. But there are some mammals in which the circle of the shoulder-girdle is completed normally on the dorsal aspect by means of ligament. The most curious instance of this is in the mole, which has the shoulder-blades elongated into three-sided shafts, the posterior ends of which are united by a short ligament which crosses over the spinal column, quite unconnected with either it or the deep muscles, an arrangement which, while it prevents them falling asunder, does not interfere with their backward and forward movement on the fulcrum of the clavicle when the animal grubs with its paws in the earth. A less remarkable arrangement where there is no clavicle is illustrated in the horse. In it a stout ligamentous band, the representation of part of the trapezius muscle of man, but containing no muscular substance, attaches the base of the spine of the scapula to the withers, and causes the movements of that bone to revolve round it. Such a state of matters is obviously well suited to the wants of an animal without clavicle and with habits of swiftness, allowing as it does free play to the forward and backward sweep of the lower or humeral end of the blade, while the pivot of the movement is removed to the upper end. In this instance, as in general in those mammals which have no clavicle or none but a sesamoid rudiment, the shoulder-blade is directed from back to breast, so as to rest its glenoid fossa over the humerus, and serve as a fulcrum for the backward and forward movement of that bone in progression; but in those in which the clavicle is developed, the glenoid fossa is thrust outwards, and the scapula is pressed against the clavicle in those movements of grasping which the presence of a clavicle makes possible in perfection. It is curious to note that in the carnivora, while many genera have a notable though in all cases imperfect power of outward and inward movement of the forelimbs, the clavicle exists in most cases in a rudimentary form, but never comes in contact with either scapula or sternum, and cannot be of the slightest mechanical service.

The question may naturally be asked, seeing that those mammals without clavicles, or which have them rudimentary, include those which use their forelimbs most of all for support and locomotion, How are their bodies supported between their shoulders? The answer is that they are supported by means of muscles; being slung between the serrati magni muscles. Nor is this any true exception to the general rule that muscular action, being an expensive thing, is never made use of in animals, where ligament will serve the purpose; for though the substance of the sling is muscular, it is not muscular action, but ligamentous, which is employed. The experiment of Weber teaches that it is when in an unstimulated condition, not when consuming fuel in the exercise of its function, that muscular fibre offers the greater resistance to being stretched beyond its natural length; and this action of the serratus magnus in quadrupeds is not the only distinct instance of the ligamentous action of muscles being called into play when they are vitally at rest; for, as I pointed out ten years ago,[1] the shoulder-girdle in the human subject is similarly maintained in its place by the trapezius, and, when that muscle is obliterated, falls downwards and forwards on the chest.

At the articulation of the clavicle with the sternum, the clavicular rises above the level of the sternal surface, and the two surfaces are separated by the strong interarticular fibro-cartilage, which is attached at its upper border to the clavicle, and at its lower border to the cartilage of the first rib. Perhaps the whole articulation deserves more careful attention than is usually given to it; for although it is subject to a certain variety, the interarticular fibro-cartilage being sometimes perfect and sometimes more or less deficient, and the sternal surface in some instances much smaller than in others, the sternal surface especially has marked peculiarities, easily studied in instances in which it is well developed. The sternal surface may be described as, on the whole, concave from above downwards, though somewhat beveled at the back of the upper margin; and in the middle it is concavo-convex from behind forwards, while inferiorly it is flattened. The whole surface is, in fact, divisible into two parts: an upper part, convex in front, but showing a depression behind; and an inferior flat part, most developed in front. The concavity referred to at the back part is sometimes scarcely recognisable, but in the best-marked specimens it forms a distinct depression with the beveled uppermost edge separated from it by a convexity which becomes more prominent as it sweeps forward in front of it and dies away in a flat surface below. The clavicular surface, much more elongated from before backwards than the sternal, is at its back part, where it is continued on the projecting posterior angle of the bone, slightly prominent, and plays against the concave hinder portion of the sternal surface; inferiorly it becomes abruptly convex, and glides on the attachment of the fibro-cartilage and on the costal cartilage beyond. The joint is surrounded by a strong capsule, which is, however, sufficiently weak in some parts to allow redundant portions of synovial membrane to be sucked in between those parts of opposed surfaces which in any position are not in accurate contact. The fore and back parts of this capsule constitute the anterior and posterior ligaments, while above and below are two ligaments requiring more special notice. The ligament above the joint is called interclavicular, because many of its fibres, passing from the upper border of one clavicle, instead of being fixed to the sternum, arch onwards to the clavicle of the opposite side. It is continuous with the posterior ligament, and its fibres are directed forwards as well as inwards. The ligament below the joint is the costo-clavicular, and lies edgewise to it, its innermost fibres being close to the posterior ligament, and its outer fibres, which are much longer, extending as far out on the clavicle as the inner end of the origin of the subclavius, and there connected with the costo-coracoid membrane—circumstances notable as suggesting an important ligamentous function of the subclavius. When the shoulder is forcibly depressed, as in raising a weight, the convexity of the lower part of the clavicular surface is pressed against the lower division of the sternal surface and the attachment of the intervening fibro-cartilage; that structure and the interclavicular ligament are put on the stretch by the revolution of the clavicle round the convexity of its surface; while between the fibro-cartilage and the upper part of the sternal surface are invaginated plications of synovial membrane. When, on the other hand, the shoulder is elevated as in pushing, folds of synovial membrane are drawn in to fill a gap between the attachment of the fibro-cartilage and the lower border of the clavicular surface; and the costo-clavicular ligament, subclavius, and costo-coracoid membrane are put on the stretch.

Thus in the sterno-clavicular articulation there is beautifully exemplified a principle of construction seen in many other joints—namely, that instead of the surfaces being conformable in their whole extent, rubbing one against the other throughout their contact, there are areas which are brought into apposition in certain positions of stability and are separate in other positions, just as portions of a wheel come without friction into contact with the ground, and similarly retreat from it. Friction is confined to the gliding parts between the areas referred to, and thus the smallest possible amount of friction in movement is combined with the greatest possible stability in particular positions. But, besides the upward and downward movement, the clavicle is permitted a backward and forward movement round its sternal articulation, and this is much more considerable when the shoulder is elevated than when it is depressed. In its most completely depressed position the outer end of the clavicle is thrown forwards and cannot be moved backwards in the slightest without a marked degree of elevation—that is to say, without shifting its fulcrum upwards on the sternal surface. As, however, the sternum in a well-built man standing erect is in a sloping position, it will be well understood I do not mean that in such a position the shoulders are actually raised when thrown backwards. It is only meant that the clavicle moves in a direction which would be upwards and backwards were the sternum vertical. So long then as the arm is hanging at rest over a vertical sternum the lower parts of the surfaces of the bones are those in use, and the joint is in one of its positions of fixity, the fixity being secured by the clavicle resting immediately beyond the joint on the front of the first costal cartilage. But when the shoulder is slightly raised, or the lower end of the sternum thrown forward, which comes to the same thing, a large amount of backward and forward movement is allowed, the clavicle moving across the convexity of the sternal surface. When the clavicle is thrown as much forward as possible in this position, as in pulling a rope, the part of the sternum in front of the convexity is pressed on, and there is a gap behind; when, conversely, the clavicle is thrown back as far as possible in pushing against an object in front there is a gap in front, and this being a position in which strength of construction at the joint is required it has a large amount of stability given to it by the prominence at the back of the clavicle being pressed forward into the concavity at the back of the sternal surface, and against the convexity in front of this, which protects it from dislocation forwards. The beveling at the top of the sternal surface, which has been alluded to as not constantly present, but which sometimes forms even a distinct facet, comes into play when the arm is raised to its utmost, as in stretching towards an object above.

---

[1] Journal of Anatomy and Physiology, 1871.

At the outer end of the clavicle, the acromio-clavicular articulation has its surfaces very small, surrounded with a strong ligamentous capsule, and with a more or less imperfect interarticular disc interposed between the surfaces. The joint permits revolution of the scapula in every direction, not prevented by the presence of the walls of the chest, or the contact of the coracoid process with the clavicle. The angle between the scapula and clavicle is opened to its utmost when the shoulders are thrown back and the arms allowed to hang, while it becomes most acute when the shoulder is shrugged. There is, then, in the passage from the one of these positions to the other a horizontal movement of the acromion round the clavicle. But there is likewise a vertical movement, for when the arm continues pendent and the shoulder is raised, the clavicle rises, while the acromion continuing horizontal is displaced from its position relatively to the clavicle in a downward direction; but when the arm is elevated, the trapezius acting, and the levator anguli scapulæ relaxed, the acromion revolves upwards on the clavicle.

The circumstances in which the coraco-clavicular ligaments are tightened are worthy of mention. The trapezoid ligament is fully stretched in pushing outwards against an obstacle, with the humerus pressed against the glenoid cavity, and in pulling across the middle line, as in drawing a bow-string. In those actions the conoid ligament is slack, except when the arm is much elevated, and the scapula thereby made to revolve, so as to separate the coracoid from the clavicle; then the inner fibres of the conoid are stretched. The conoid ligament is stretched in pushing forwards; the humerus being then pressed against the acromion and the tightened posterior fibres of the capsule of the shoulder-joint, and thereby pushing back the whole scapula, coracoid process included. The conoid ligament is likewise stretched and the trapezoid relaxed in pushing downwards, and in hanging by the arms from above. In pulling from the side to the middle line, both the conoid and trapezoid are relaxed, and the strong acromio-clavicular fibres stretched.

It is in pushing downwards and in shrugging the shoulder that the coracoid comes into contact with the clavicle, and this appears to me to have a certain surgical interest in connexion with fractures of the outer end of the clavicle. Surgeons are agreed that this injury is much more frequently produced by direct violence, and if it be asked why does the fracture always take place close to the trapezoid ligament, and most frequently internal to it, I think that one must not only note the flattened form of the outer end of the bone, but must answer that it is broken upon the coracoid process, precisely as the patella is fractured transversely by its middle facets being pressed against the femur when the quadriceps muscle and ligamentum patellæ are pulling at nearly a right angle one to the other, or as a stick held at both ends may be broken across the knee. The rarity of the occurrence of fracture of the outer end of the clavicle from falling on the hand arises from the circumstance that in falling with great violence the arm is usually outstretched, while it is only when the humerus is at less than a right angle with the humerus that the coracoid process is pressed against the clavicle. That is precisely what happens when the victim lifts his shoulder in wincing from an expected blow, but is not likely to occur from a fall, except when descent takes place vertically, feet downmost, through a hole, and the only support to clutch at is below the level of the hands. The elevated position of the arms in falling is favourable to the occurrence of the inner fracture of the clavicle, because the direction of the resistance of the ground to the outstretched hand is such as to give a further bend to the great curve of the bone.

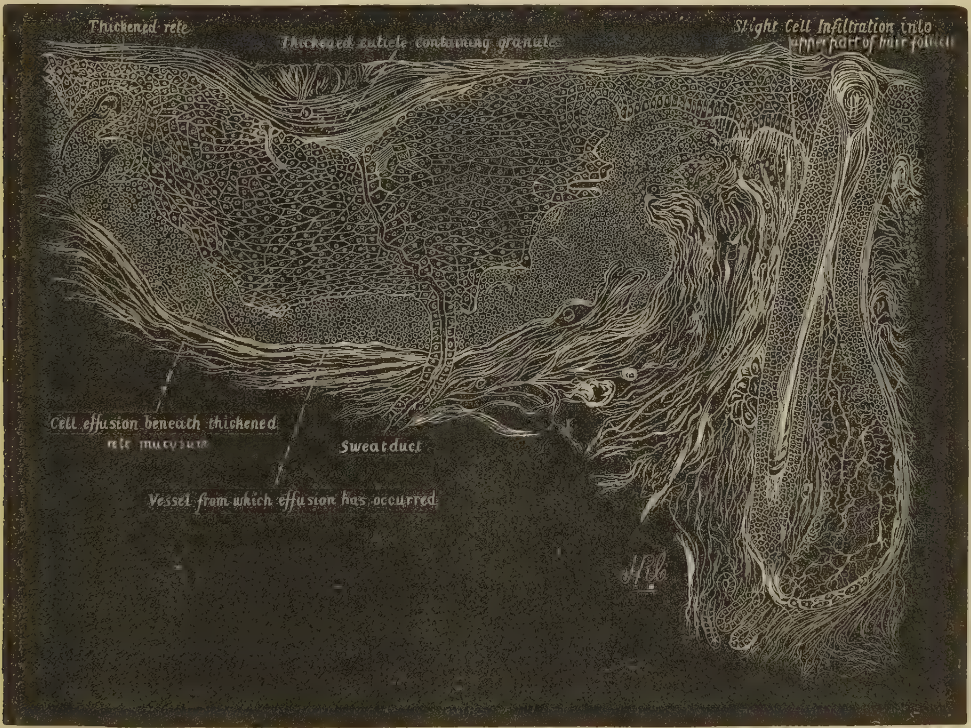
ABSTRACT OF THREE
Clinical Lectures,
WITH MICROSCOPICAL DEMONSTRATIONS,
ON
TRUE LICHEN AND ITS VARIOUS FORMS.
Delivered at University College Hospital,

BY H. RADCLIFFE CROCKER, M.D., M.R.C.P,
PHYSICIAN TO THE SKIN DEPARTMENT OF THE HOSPITAL.

LECTURE I.

ADOPTING Hebra's definition of Lichen as "those cutaneous affections which are attended by papules the result of a definite morbid process, and undergoing no metamorphosis in their entire course," I shall include under this definition—1. Lichen Planus or Ruber: (*a*) general; (*b*) limited. 2. Lichen Scrofulosorum. 3. Lichen Pilaris. I shall also allude to some other papular diseases which are still classed among the lichens by some authors.

1. *Lichen planus.*—Having discussed the clinical features, I will now pass on to its histology and pathology. All writers have laid great stress upon the implication of the hair follicles as being the especial feature of the disease, and, moreover, that the process is a deep one leading to an hypertrophy of the root sheaths about the papilla of the hair, so that the hair root has a knobbed appearance like the lobes of a racemose gland. Hebra, Neumann, Kaposi, and Biesiadecki have examined portions of skin from Lichen ruber, but they appear to have all been chronic cases, and the sections I show you now are, I believe, the first taken from recently formed papules. Now, I do not dispute that in the advanced stages the appearances are as Neumann describes, and that some, at all events, of the hair sacs and root sheaths do undergo hypertrophic changes. These, however, are but sequential to the early part of the process, and do not represent the true pathology of the disease. In addition to the sections, I have placed under the microscope hairs pulled from the centre of lichen papules, in which atrophy not hypertrophy, is the feature, while other hairs, to which the internal root sheath is still attached, appear unaltered. Dr. Fox, on the other hand, figures a hair which he removed from a papule, in which there was hyperplasia of the attached root sheaths, but the hair was unchanged. In spite of this I believe I can adduce clinical as well as microscopical evidence to show that, so far from the hair follicles being the chief seat of the disease, they are in most cases rather the exception than the rule, and, so to speak, almost an accident of the disease. In saying this I am, I know, diametrically opposed to the hitherto received views, but the facts appear to point strongly to this conclusion. The skin on which these re-



Thickened rete
Thickened cuticle containing granule
Slight Cell Infiltration into upper part of hair follicle
Cell effusion beneath thickened rete mucosum
Sweatduct
Vessel from which effusion has occurred

marks are founded was taken first from the front of the thigh in the case of a woman aged forty; secondly, from a man aged fifty-six who had had an infiltrated patch on the side of the leg just above the ankle for some years, and while under observation a copious outbreak of papules appeared on the forearm, especially on the front, the sides of the legs, the thighs, flanks, and lower parts of the abdomen. Portions of skin with papules were removed close to the infiltrated patch, and from the front of the forearm. I have examined upwards of a hundred sections made from these portions of skin, and you can verify the following observations for yourselves. First, in the skin taken from the thigh you will see that the papule is formed by a cell effusion from one of the vessels of the superficial plexus pushing up the superimposed epithelial layers. This cell effusion comes entirely from the upper wall of the vessel, there being no cells or other changes below, and in this particular papule the cells show an indication of being in lines, as if streaming directly away from the vessel; several papillæ are involved in this process, and here and there a sweat duct may be traced passing through the papule, and generally one can be made out in the centre. The cell effusion terminates abruptly at the sides. The papillæ are somewhat flattened out, and the cells of the rete mucosum have undergone a moderate amount of proliferation; the horny layer is but little changed, there is a slight loosening of the upper layers over the centre of the papule, but that is all. You will note that in this case the cell effusion forms three-quarters of the papule. In the skin taken from the forearm of the man the appearances are somewhat different, owing to the relative proportion of the component parts of the papule being altered. The greater part of the papule is not here made up of the cell effusion, but of the enormously proliferated rete mucosum, which is, in its turn, three times as deep as the cell effusion. The cells at the lower part of the rete are flattened instead of being perpendicular, while the upper layers, the stratum lucidum, and granular layer are also abnormally distinct. The horny layer is only thickened over the centre of the papule, and shaped like a broad inverted cone, which fits into a corresponding depression of the rete like a plug. Now if this horny layer should be thrown off, as we know is frequently the case, we should get the appearance of umbilication, which is sometimes seen, and is usually explained as the open mouth of a hair follicle, and may be true of some papules. Scattered through this layer are some minute refracting globules, which, Neumann states, resist ether or chloroform; their nature is not at present explicable. Externally, the horny layer is at the same level in the centre as at the sides. The apex terminates in the orifice of a sweat duct, which can be traced through the papule, and for a short distance beyond the lower side of the vessel. The cell effusion does not terminate so abruptly as in the first series, but embraces two or three papillæ which are enlarged both laterally and vertically, the interpapillary processes coming down lower than usual. The papillary vessels are abnormally distinct. I have chosen the section now under the microscope, because close to the papule a complete section of a perfectly normal hair and its sebaceous gland is seen. There are a few cells from the adjoining papule immediately adjacent to the hair sheath, just beneath the rete, but nothing more. On the other side of the hair there are no cells in immediate relation to it, but two of the papillæ just beyond it contain a little cell effusion, and there are a few cells also, about the upper part of the sweat duct, which comes down a little way from the hair. Except that some of the orifices of the hair follicles are funnel-shaped and tightly packed with horny scales, this is all the change that any of the sections show in the hair follicles. The difference between the first and second series of sections may be explained by the supposition that the processes differed in intensity; consequently, in the first series, where the inflammation was more acute, the cell effusion was the main feature, while in the second, of less intensity, epithelial proliferation characterised them. The third series were made from the skin taken at the border of an infiltrated patch. Here the cell effusion, though limited below by the superficial vessel as before, was much more diffused laterally; all the vessels of the affected papillæ were markedly dilated. The rete was much increased in depth; but the horny layer very little, if at all, thickened. The interpapillary processes were much larger, and some broader; and thus the papillæ also were enlarged in length and breadth. On the left side of the section the commencement of the infiltration is visible, accompanied by the downgrowth of the rete mucosum. No changes in the hair follicle were observed in this series; indeed, only an occasional transverse section of a hair was observed. Now, from the sections alone, all that can be actually proved is that the process is a superficial inflammation in the early stage, and that it may occur independently of the hair follicles. Still, I was struck by the fact that in a disease in which the hair follicles were supposed to play the most important part, skin taken from three regions of the body showed no marked perifollicular inflammation, and

I was thus led to study again the clinical aspects and the analysis of cases, and the consensus of authorities revealed the curious fact that this so-called follicular disease most frequently attacked the regions where there were the fewest hairs, such as the front of the forearms, especially near the wrist, the flanks, inner side of knees over vastus internus, and the side of the legs, especially above the ankles; to say nothing of the palms, soles, nails, and mucous membranes being occasionally involved; while only in a small minority were the backs of the forearms and hands, and other situations where the small hairs are abundant, involved, many of these cases having begun in the more usual situations, and subsequently implicated the other parts. Since these considerations were forced upon my notice I have only had the opportunity of examining two cases; one that we have seen to-day, the other a mild case in private, a man in whom there was a single patch, the size of the hand, below the knee on the inner side and back of the leg; about a finger's breadth of the patch encroached on the hairy part of the leg, the rest was on the nearly hairless part; there were a few papules also on the outer side of the leg above the ankle. In both these cases I searched carefully for papules situated round the hairs, and in neither were there well-marked instances of it. There were, comparatively speaking, a few hairs with some redness round, and some broken short, as though their nutrition had been interfered with, but among the number of well-marked papules, I could find not one with the hair in the centre, though it was quite common to find a well-developed papule with a healthy hair almost touching it.

Of course, there are plenty of cases where the hairs are more implicated than in these two; but even then I am inclined to think that it will be found that follicular papules will be far outnumbered by the papillary ones. Even if in some cases this were not so, and the follicular inflammation predominated, I still contend that the disease stands in relation to the hair follicles very much in the same position as eczema, in which, though usually a disease of the flexor surfaces involving all the skin structures, it sometimes picks out the hair follicles as the seat of the inflammatory process. These cases were formerly reckoned among the lichens, but are now recognised as mere varieties of eczema. I have pointed out to you that a sweat duct can generally be traced in the centre of the papule, and two or three may be involved in it, and that the apex of the cone of the corneous layer coincides with the orifice of the sweat duct. Is this an accident of situation, so to speak, or has the sweat gland or its duct anything to do with the production of the papule? With regard to the sweat gland, I regret to say that the skin was not removed sufficiently deeply to speak with absolute certainty about many of them; all that I observed were healthy, but I am inclined to think, from the frequency of its central position, that it constitutes a determining point for the formation of the papule round it, just as the hair undoubtedly does in some cases, though, I contend, not so frequently as general opinion would ascribe to it. There is another fact which tends in this direction. Mr. Hutchinson, with his usual accuracy of observation, has noticed that wherever the clothes are fastened in close contact with the skin, such as the waist, the site of the garters, the pad of the truss when a hernia exists, &c., there the papules are most thickly distributed. In the case before you this is very noticeable below the knees, where the garters are fastened. Mr. Hutchinson ascribes this to pressure. May it not be, however, that the increased heat produced by close contact is the real agent? The general conclusions I would draw, therefore, are—

1. That the process at its commencement is entirely superficial.

2. That it consists of an inflammatory effusion from the superficial plexus of vessels, the cells in the horizontal vessels coming only from the upper wall.

3. That all the vessels of this plexus are notably dilated and the papillæ enlarged by down-growth of the interpapillary processes.

4. That all the epithelial layers undergo proliferation, those in the rete mucosum taking the most prominent part in the formation of the papule.

5. That the involvement of the hair follicles is not an essential nor the main feature of the process in most cases; but—

6. That the sweat ducts have more often an influence in determining the position of the papule.

"TREATMENT OF PAIN BY MECHANICAL VIBRATIONS."

By J. MORTIMER GRANVILLE, M.D.

The publication of certain results obtained in an investigation which I have been pursuing for some years past having been to a large extent anticipated by a paper which appeared in *Le Progrès Médical* of the 5th inst., from the pen of M. Boudet de Paris, ancien interne des hôpitaux de Paris, I have no alternative but to bring my researches, together with such *facts*, real or imaginary, as I have succeeded in eliciting, under the notice of the profession here and on the Continent. Indeed, I owe some explanation to many friends in England and in Paris for having so long delayed to report the progress of my experiments. Nevertheless I break silence thus early with the greatest reluctance, and only under the pressure of circumstances. As regards the accident of "forestalling," if I am not mistaken M. Boudet de Paris will have greater cause than I have to regret what I cannot but feel is the premature announcement of a discovery. On the 5th of August, 1878, Professor Brown-Séquard wrote me as follows:—"If it (the instrument employed in these experiments) has the power you state, you have certainly made a very important discovery." I could not but feel that there was a virtue in that "if" to enforce reserve until other judgments besides my own were fully satisfied. Such grave responsibility attaches to every member of the profession who ventures to suggest a new, or seemingly new, method of treatment, and who dares to hold out a hope of remedy or relief for the miseries of mankind, that I, for one, must confess to a great shrinking from the hazard of rushing into print prematurely. This feeling alone has induced me to keep silence during the last three or four years, and I am convinced the same motive has influenced the several physicians who have kindly tried my method and employed my Percuteur, to wait until convinced of their validity and value before giving to either the sanction of their authority. Among the gentlemen to whom I have submitted my speculations, and shown my instrument, I may mention Professor Brown-Séquard, Professor Ball, and Dr. Oscar Jennings of Paris, and Drs. Ringer and Gowers of London. These names are in themselves sufficient to guarantee that if the results obtained by experiment had been such as to establish my conclusions they would long since have been announced, and unless I am greatly mistaken the results recorded by M. Boudet de Paris cannot, in any therapeutical sense, be more trustworthy than my own. I will now tell the story of my investigations, and thus mark the point reached in the search for a new remedy.

As far back as 1862–3 I was, in the course of certain clinical studies of mental and sensory phenomena, induced to believe that many forms of the sensation we call "pain" were, in fact, unnecessary, and might be *interrupted* by appropriate mental and physical methods and appliances. My first observations were made in connexion with the paroxysmal, or recurrent, pains accompanying the uterine contractions in the natural process of parturition. On the 4th of May, 1864, Dr. Graily Hewitt was good enough to communicate the results of my experiments and to show certain apparatus, to the Obstetrical Society of London. In a paper "On the Application of Extreme Cold as an Anodyne in the Pain attendant on Parturition," a short abstract of which will be found in The Lancet of July 9th, 1864, I contended that the sensations of pain experienced by the parturient woman were *not* invariably synchronous with what, for want of a better name, we term the pains of labour; and from this and other premisses—for example, the circumstance that they are commonly "referred" to regions more or less remote from the contracting uterus, or the dilating external passages, in which the real seat of the pain might have been supposed to be located—I deduced that the pain attendant on labour is *neuralgic* in character. I had constructed small boxes or chambers of such sizes and shapes as to admit of their being applied to the *supposed* seats of the pain. These were filled with freezing mixture, and the effect of sudden contact in some thirty cases was to arrest the sensation of pain without in the least degree lessening the force of the uterine contractions. The experiment was of course simply interesting as bearing on the *nature* of the pain, as this process was too troublesome to admit of its adoption in practice; albeit some of the persons on whom I had the opportunity of trying my method experienced such striking relief that on subsequent occasions I believe they asked that the measure might be repeated. Having so far persuaded myself that this form of pain was neuralgic, and that if the nerve affected could be strongly impressed, so as to *change* its state of irritation, the pain would cease, I proceeded to try the effect of rapidly tapping the skin over the fifth nerve in ordinary facial neuralgia with a Bennett's percussion hammer, using the ivory pleximeter as a shield. The results obtained by this method were very remarkable. Still, I simply thought of arresting the morbid action by *shock*. Later on—it is only possible to sketch the outline of the inquiry—I was led, by the light thrown on Newton's doctrine of concords and discords, by Grove's generalisation as to the correlation of forces, and more recently by Professor Tyndall's beautiful series of experiments with sensitive flames and musical burners, to believe that the results of the tapping were not, like the interruption with shock produced by the sudden application of cold, due to a mere arrest of the painful state of irritation into which the nerve had been thrown, but were, in fact, brought about by the extinguishment of a morbid—that is, either inordinate or disorderly—set of vibrations by the superimposition of another, incompatible or discordant set of vibrations, mechanically produced. With this notion I set to work to devise an instrument which should give a known number of blows per second, and thus admit of this new phase of the inquiry being pushed farther. Such an instrument was made for me at the establishment of Mr. Streeter, of New Bond-street, from a sketch and specification dated Jan. 5th, 1877. With the "percuteur" thus made, and others by M. Collin, of Paris, results which I would characterise as *suggestive* rather than *conclusive* have certainly been obtained. They are, in brief, as follows:—

The sensation produced by the application of the instrument over a healthy nerve, so situated as to be readily thrown into mechanical vibration, closely resembles the effect of a weak dose of the interrupted current of electricity, and if it be prolonged the vibration extends its area, exciting first formication or tingling, then a sensation of numbness, and finally some twitching of the superficial muscles. A nervous headache, and even migraine, may be induced by the application of the percuteur to the frontal ridges or the margins of the orbit. By the intervention of a thin plate of metal, or even stiff paper, the vibration may be readily propagated through a considerable region of the surface of the body, and in time the deeper muscles will frequently begin to act. I have even produced an involuntary movement, not unlike tendon-reflex, by applying the percuteur for some time over the tendon of the rectus femoris above the patella. Still more notable has been the fact that by laying a sheet of paper over the abdomen, and moving the percuteur slowly in large circles round the umbilicus, the intestines have *seemed* to be excited to vermicular movement, and the bowels commenced to act. These results have not been constant, but have occurred with sufficient frequency to indicate that the experiments already made are worthy to be repeated.

With respect to the relief of neuralgic pain, the operations of the instrument are certainly very remarkable, but not, in my judgment or in that of other observers, such as to justify the assertion that it constitutes an appliance for the relief of pain. In some instances—pretty numerous—the pain of neuralgia in the branches of the fifth has been quickly arrested by its application, and has not soon returned, or, if it has done so, has again unmistakably yielded. In other instances the sensation has been aggravated by the augmented state of vibration into which the nerve has been thrown through the shaking of the adjacent tissues. And here I must mention a point to which I attach the greatest moment, and which, I think, will hereafter be found to prove the key to the whole phenomena. A comparatively high number of vibrations per second seems to relieve a dull aching, a "massive" or grinding pain, while an acutely pitched and quick pain is most frequently arrested by a slower movement of the instrument. If I may step beyond the province of a simple reporter of clinical phenomena for one moment, I will take leave to say that I think these results go to support my theory that it is by the introduction of *discord* into the rhythm of the morbid vibrations of the painful "state" the change which brings relief is effected. To apply the percuteur with a high rate of blows per second will aggravate the morbid state when that is itself a series of rapid vibrations, and in the same way a low speed of percussion increases, instead of relieving, the pains of a low-pitched and slow "boring" or "grinding" sensation. Acute or sharp pain is, I believe, like a high note in music, produced by rapid vibrations, while a dull, heavy, or aching pain resembles a low note or tone, and is caused by comparatively slow vibrations. A slow rate of mechanical vibration will therefore interrupt the rapid nerve-vibration of acute pain, while quick mechanical vibration more readily arrests the slower. The aim—if I am right in my conjecture—should be to set up a new set of vibrations which shall interrupt or change the morbid set by introducing discord. Failure in the application of this principle will, I believe, be found to explain the failure to put an end to the pain; and I have, accordingly, set as much scientific value on my failures as on my successes.

My percuteurs are all defective in one particular: although they consist of a simple train of cogged-wheels worked by a spring and acting on the lever, which carries an ivory hammer, and are provided with an indicator, which shows the speed, and a screw movement to control it, they do not obey the will of the operator, because the slightest pressure of his hand shortens the arc in which the hammer works, and proportionally accelerates the stroke. M. Collin has modified my instrument, but he has not, so far as I am aware, entirely remedied this defect.[1] If M. Boudet de Paris can so improve his instrument as to obtain control of its movements and to propagate a *known* set of vibrations, he may succeed better than I have done; but I should be glad to find that the result could be obtained without the use of electricity, as it is important to the scientific interest of the instrument—and as yet it cannot, I am convinced, be said to have a therapeutic value,—to show that the vibrations are purely mechanical, and propagated through the tissues by a force acting externally. It would be one thing to induce change of the organic vibrations by internal force, and quite another to overpower the internal movements by force operating from without. The result may be the same, but the two methods of reaching it are essentially different.

That all nerve action is vibratile, and that the neuralgic state consists essentially in an abnormal set or series of vibrations into which the nerve has been thrown—perhaps by a jet of cold air, or a mechanical or chemical irritant—I have no doubt. That this state may be changed by mechanical vibrations propagated to the nerve-sheath and its contents through the adjacent tissues I am convinced. I have not, however, as yet, got one step further than persuading myself that these are genuine propositions, and capable of demonstration by experiment—to wit, the causation of neuralgic pain and the induction of the neuralgic state generally by mechanical vibrations, and the relief of these conditions, when they exist, by the same method. The essence of the process is disturbance and change of the rhythm. When I began to study the effect of cold, I thought the results obtained were reached by deadening the nerve or "lowering its sensibility," as we say; but I soon found that the effect was proportioned to the intensity of the shock produced by the sudden contact with the cold substance, not the duration of the chilling process. When cold gives relief by its continuance, rather than instantly on its application, I think that is because the morbid vibrations of the nerve cannot, for some physical reason, be interrupted by shock; possibly the nerve is situated too deeply, or is covered by dense tissues, or lies so loosely amid its surroundings as to be practically insulated, and the morbid vibrations are not arrested until the cold contracts the surrounding tissues, and causes them to mechanically grip the terminal twigs of the nerve which is vibrating painfully. In some instances the percuteur is so powerful as to arrest the morbid vibrations on one side and propagate a painful set of vibrations through the centre to the other side. This may strike the reader as a mere assertion, but I am persuaded it will be found to be borne out by experiment. If I am not greatly mistaken, the percuteur, or some more perfect mechanical vibrator, will do all that "metallo-therapy" has achieved in the same class of cases. We do not sufficiently appreciate the effect of subtle or subtily-applied forces acting on the organism. When the so-called mesmerist induces a state of hypnotism in his patient by simply blowing on the face, or when by "passes" he impresses the retina, he acts *physically* on the terminal twigs of highly sensitive—and generally educated—nerves, and induces a set of actions which, though notable in themselves, are no more mysterious in the manner of their production than the involuntary strong muscular action excited by the "tickling" of a hair or a feather, or the crawling of an insect. As a matter of fact, the surface is generally more *powerfully* impressed by these minor applications of mechanical force than by the greater. If you touch an exposed sub-cuticular surface lightly you give extreme pain; if you grasp it somewhat firmly you cause less suffering. This is quite as likely to be because, in the first case, the terminal twigs of the sensitive nerves are set vibrating, whereas in the latter vibration is prevented, as due to the local blood-change to which these results are commonly attributed. While a poultice is moist, and clings to the surface of a sore, it soothes by holding the nerve-fibres still; when it begins to dry, and they are liberated, the poultice becomes an irritant. The physical basis of the so-called hysterical state, or the peculiarity of nervous organisation which predisposes to hysteria, is, I think, simply a class or type of structure which renders the nervous elements especially liable to vibrate in their sheaths, and thus exposes them to the risk of falling readily into any rhythm which the will, the physico-mental environment, or perhaps even the proximity of similar structures vibrating in other bodies characterised by the same physical organisation, may suggest. If musical burners supplied from different reservoirs of gas will presently vibrate in concord; if strings or reeds vibrating at the same time, though a short distance apart, will fall into harmony, why is it unlikely that nervous organisms possessing the same qualities of physical structure should exhibit a corresponding affinity? Science points clearly to physical states as the basis of nervous and mental phenomena. The female organism is characterised not inaccurately, though popularly, by the phrase "finely strung nerves." It is literally *mobile*, and it is chiefly among females the phenomena of hysteria, and the allied states, are observed. When the symptoms and conditions so designated do occur in the male, the individual organism is generally of a feminine character.

---

[1] The French instrument may be seen at Messrs. Weiss and Son's, 62, Strand.

In conclusion, I would venture to predict that it will be found that nerve action, both normal and abnormal, consists of vibrations, and that *other* mechanical vibrations set up and propagated by any mechanical apparatus or appliance, acting from without and propagated through the tissues, may be made to modify the internal movements; that normal vibrations consist of movements of the constituent parts of a nerve within its sheath, and that when these become inordinate or disorderly they are propagated to the sheath itself, and then become painful; that under this last-mentioned condition the wave of vibration is likely to be propagated along the sheath of the nerve, and through it to the sheaths of other nerves with which the first in order of disturbance may be mechanically related, either by direct contact or through intervening tissues; that the action of irritants applied to the skin is mechanical, producing contraction of the tissues, and either first gripping and then relaxing the terminal twigs of the nerves, thus throwing them into mechanical vibration, or so changing the constitution of the bed in which these terminal twigs lie as to oppose a mechanical obstruction to their natural vibration, and thereby convert it into a morbid rhythm. This, indeed, has been demonstrated by Dr. Ringer, in his classic treatise on Therapeutics, in connexion with the *modus operandi* of blisters. These may be set down as crude speculations, but they are the results to which experiment and common-place reasoning point, and they are in harmony with a view of the phenomena of nerve-action and pain which the inquiry I am pursuing forces upon me, and by which nearly all the wonders of the hysterical school of medical philosophy may be explained. I cannot claim to have discovered a "cure" for neuralgia, or even a *certain* method of treatment for its relief. The time has not arrived when it may be possible to commend this *new method* to the notice of the medical profession as a known agency for the alleviation of suffering; but as the facts have been prematurely published I think the method should be tried.

Welbeck-street.

ON A NEW METHOD OF SUPPLEMENTARY ALIMENTATION.[1]

BY A. ERNEST SANSOM, M.D. LOND., F.R.C.P.

I WISH to bring under notice a plan of treatment which, I think, is scarcely known in this country, but which shows promise of much practical usefulness. Every practitioner will, I am sure, acknowledge to an aching of heart over cases in which he feels that a little addition to the powers of nutrition, a little supply to the tissues of the materials necessary to their well-being, may turn the scale from death to life, and yet that little "aliquid" is not to be found. The difficulty presents itself in acute as well as in chronic cases, in conditions of immediate as well as prolonged emergency. Take the case of fevers in which a number of factors co-operate to induce a condition of danger—nutrition is not only in abeyance, but there is rapid waste. It is unnecessary to say that an increase in nutrition or a lessening of waste may make all the difference between death and life. Then, in chronic affections such as pulmonary phthisis the experience of late years tells to the effect that if by means of a healthier general nutrition the pernicious metamorphosis of tissue which results in caseations or tubercles can be modified, we may turn the scale towards recovery. In sudden emergencies, as from alarming hæmorrhages, the craving for a rapid supply to the exhausted organism prompts us to adopt transfusion of blood, and in a like condition brought about by chronic maladies such as prolonged anæmia, we are sometimes called upon to consider the question of this most perilous method of treatment. We have presented to our view every day of our lives the probability of a case coming before us in which, if we could only suggest a method of conveying to the tissues the pabulum which they need, we might have the satisfaction of seeing our patient recover.

Of course in all the cases now presented to us I assume that we have made up our minds that appeals to the stomach are unavailing. We have done, and still do, what we can to ensure to the full the absorption and assimilation of all that we can present to the alimentary tract through the mouth. Yet nutrition fails, and we have to think of plans of administering food by the rectum, by the skin, or by injection into the blood itself.

It is only *feeding by the rectum* that I shall now ask for consideration. The experience of every medical practitioner, I am sure, will tell of cases in which nutritive and stimulant enemata have been of essential service. We can point to cases kept alive—barely alive probably, but alive—by them. Of nutritive and stimulant enemata hitherto employed I may briefly refer to the following:—

1. *Hot Water.*—It has been recommended in certain conditions of collapse to administer, by the rectum, water at about the temperature of the blood. This would appear to repose on a reasonable basis. In many such conditions of halt on the part of the circulation a mere addition to the volume of the circulating blood has been successful in re-establishing, at least temporarily, the action of the heart. This is the rationale of action in the cases in which the injections of weak saline solutions into the veins in cholera collapse have been followed by improvement. There is no doubt that fluid is absorbed from the mucous surface of the large intestine, and so enters into the circulation. In sudden collapse, therefore, the practice of administering a warm fluid enema is decidedly to be recommended.

2. *Alcohol and Diffusible Stimulants.*—There is no doubt that the mucous surface of the lower bowel absorbs alcohol, ammonia, &c. The addition of these agents to a fluid enema may be considered as a matter of discretion. While reasonable and scientific additions to simple aqueous enemata, however, it is well to point out that alcoholic admixtures with nutritive enemata consisting of solutions of albumen are unscientific and unsound, the alcohol tending to coagulate the albumen.

3. *Medicinal Agents.*—It is well known that medicines may be absorbed from the mucous surface of the rectum.

---

[1] A paper read before the East London and South Essex District Branch of the British Medical Association.

This is proved to us by our frequent experience with regard to opiate enemata, as well as by the action of the hosts of medicated suppositories so commonly employed. We find that absorption of the medicine is not so complete as when it is presented to the stomach; so we are accustomed to administer larger doses per rectum. Moreover, we learn that rectal absorption is more tardy. Dr. A. H. Smith found that eight grains of fluid extract of rhubarb in twenty grains of water, at a temperature of 73° F., gave the characteristic red colour to the urine, on the addition of caustic potash, in sixteen minutes after injection into the stomach. In cases where the same quantity at the same temperature was injected into the rectum the period after which the reaction was evidenced was sixty-five and seventy minutes. But when the temperature of the enema was raised to 108° F. the reaction was obtained in forty minutes.

Whilst absorption, then, of medicines by the rectum is more tardy and less complete than absorption by the stomach, there is abundant evidence of administration by the bowel being a very important means whereby fluids, stimulants, and medicines enter the blood.

4. *Solutions of Albumen.*—Here also we have evidence of absorption, but under narrowly-defined limits. The rectum is but a passive pouch; it has no power of preparing albuminous bodies for absorption as the stomach has, and such absorption is only effected by dialysis into its venules. It follows, therefore, that albumen is only absorbed when it is in aqueous solution. We know how very limited is the absorbability of unmodified albumen. It is evident, therefore, that of the albuminous contents of nutritive enemata as commonly employed only a fractional proportion is taken up into the blood-current to subserve any useful purpose of nutrition.

5. Lastly, there is fair evidence to show that fatty matters, such as those pertaining to milk and cod-liver oil, are capable in some degree of absorption from the rectum. (For formulæ for enemata falling under the foregoing classification, see Tanner's "Practice of Medicine," vol. ii., p. 480.)

Such, then, were the enemata long in common employment, and such are those which now are very generally employed. A very great improvement was, however, effected when efforts were directed to render the albuminous constituents of a nutritive enema more capable of absorption. I have already said how very limited is the amount of albumen possible of absorption in an ordinary nutritive enema. The improvement consisted in administering the albuminous constituent of the enema in the form of *peptone*, such peptone being produced by the action of pepsine or pancreatine upon albuminous bodies. Pepsine used to be employed, but more recently preference has been given to pancreatine. Dr. Leube mixed one part of finely minced pancreas with three parts of scraped meat, adding warm water sufficient to make a small injection, and sometimes a slight proportion of fat. He found by experiments upon dogs that a considerable quantity of nitrogen was thus conveyed to the body. Dr. Horace Dobell has given the following formula:—Cooked beef or mutton, finely grated, ¼ lb.; pancreatic emulsion (Savory and Moore), 1 oz.; pancreatic powder, 20 grs.; pepsine (pig's), 20 grs. Mix the whole in a warm mortar quickly, and add one tablespoonful of brandy, and enough warm water to bring the mixture to the consistency of treacle. Inject from an elastic enema bottle as quickly after the mixture has been made as possible, and let it be retained. More recently pancreatic extracts have been employed as peptonising agents. The liquid extract or the saline extract of pancreas is added to milk, milk-gruel, or juice of meat, and kept for some time at a temperature of about 140° Fahr. The mode of preparing such peptones, whether for administration by stomach or by bowel, is fully described in Dr. W. Roberts's valuable Lumleian Lectures "On the Digestive Ferments, and the Preparation and Use of Artificially Digested Food." Speaking particularly of administration per rectum, Dr. Roberts's says, "The enema may be prepared in the usual way, with milk-gruel and beef-tea, and a dessertspoonful of liquor pancreaticus should be added just before administration. In the warm temperature of the bowel the ferments find a favourable medium for their action on the nutritive materials with which they are mixed, and there is no acid secretion to interfere with the completion of the digestive process. I have now had some experience in this method of alimentation, and have been satisfied with its success. In one case, a patient suffering from post-pharyngeal abscess, which entirely occluded the œsophagus, was nourished exclusively for a period of three weeks (until the abscess broke) on enemata of milk-gruel mixed with pancreatic extract."

(To be concluded.)

ON THE ADVANTAGES OF CLOSING THE SAC BY CATGUT SUTURES IN HERNIOTOMY.

BY F. A. SOUTHAM, M.A. OXON., F.R.C.S.,
ASSISTANT-SURGEON TO THE MANCHESTER ROYAL INFIRMARY.

IN the operation of herniotomy, where the sac is opened, it is, I believe, the usual custom (excluding, of course, those cases where a radical cure is performed at the time of operation), after dividing the stricture and returning the bowel into the abdomen, simply to bring together the margins of the cutaneous wound with sutures of silk or silver wire. If, however, the cut edges of the opening in the peritoneal sac are in addition accurately brought into contact by means of catgut sutures, considerable benefit is derived, both as regards the more speedy healing of the wound and the prevention of extension of inflammatory action from the superficial structures to the interior of the sac.

The advantages of this simple proceeding are as follows. In the ordinary method of operation, when skin sutures are merely employed, and where, consequently, the edges of the wound in the sac are not brought into accurate contact and maintained in that position, but are left to adjust themselves as they best can, even though a drainage-tube be used, a ready way is left for the drainage backwards of inflammatory discharges into the sac through the opening that remains in its walls. If, however, the margins of the opening in the sac are brought into exact apposition by means of catgut sutures, this result will not occur, for as wounds in the peritoneum heal very rapidly, union of its cut surfaces will probably have taken place before any discharges have formed in the wound; consequently, instead of draining backwards into the sac, where they would tend to set up a local peritonitis which may afterwards spread, they will make their way downwards between the integuments and outer surface of the sac to the lower part of the skin-incision, where they will discharge themselves externally, if a drainage-tube has been inserted or an opening left for that purpose. For the same reason, if any recurrent hæmorrhage takes place after the conclusion of the operation, it will make its way externally, instead of gravitating backwards into the sac.

Though the operation of herniotomy may be performed antiseptically, yet from the situation of the wound and from the movements of the patient often tending to loosen the dressings and allowing the air to penetrate beneath their margins, difficulty is not unfrequently experienced in the after-treatment in keeping the wound perfectly aseptic. By the employment, however, of strict antiseptic precautions during the operation, and by the closure of the opening in the sac at its conclusion, the operation itself may in a sense be compared to one in which the sac has not been opened, and even if septic particles should subsequently, from some unpreventable cause, gain access to the wound, so that putrefactive changes are induced in its interior, the same condition may still be considered to exist; for under the most unfavourable circumstances it is not likely that this complication will occur within the first eighteen or twenty-four hours, by the end of which period considerably firm union will probably have taken place in the wound of the peritoneal sac, forming a barrier which will completely shut off its cavity and prevent the entrance into it of any septic matter.

I have recently availed myself of this modification of the method usually employed in closing the wound in six cases of herniotomy performed antiseptically in the Manchester Royal Infirmary, having, after reducing the bowel and clearing away all the blood clots and fluid from the interior of the sac, carefully adjusted the cut margins of its peritoneal walls, and brought them as nearly as possible into exact contact by catgut sutures introduced at a distance of about a third of an inch from each other and afterwards cut off short close to the wound. The margins of the skin-incision were then brought together by sutures of carbolised silk in the usual manner.

In five out of the six cases the result was most satisfactory, the skin-incision in each instance healing at once by first intention, with very little general elevation of temperature, and without a trace of that deep-seated local pain and tenderness which are so often present, and which then indicate a certain amount of localised peritonitis.

In the sixth case death ensued from perforation of the bowel about twenty-six hours after the performance of the operation; but in this instance also union was apparently taking place by first intention, and, on post-mortem examination, the margins of the opening in the sac were found to be firmly adherent together.

Peritonitis is, without doubt, the most formidable complication that we have to encounter both before and after the operation of herniotomy, and is, in the majority of cases, the immediate cause of death. Though we often find this condition already present or impending at the time of operation, yet in many instances it only makes its appearance after an interval of thirty-six or forty-eight hours, and in those cases where there is nothing in the condition of the sac or its contents at the time of operation to account for its subsequent appearance, it seems not unlikely that it may arise simply in consequence of extension of inflammatory action from the cutaneous wound, especially in the case of the old and feeble, whose powers of repair are not so great, and where the wound, not healing so readily, is more liable to become the seat of septic changes. If, then, by this simple proceeding, adopted merely as a safeguard against some of the later complications of herniotomy, and without any idea of producing obliteration of the sac, as in the operations for radical cure, we can, to some extent, prevent the extension of inflammatory action from the superficial wound to the interior of the sac, we at once eliminate one of the causes upon which the occurrence of peritonitis after herniotomy must, in many instances, depend.

Manchester.

STERILITY DUE TO ANTEFLEXION OF THE UTERUS, TREATED BY STEM AND SHIELD.

By A. WYNN WILLIAMS, M.D.

IN reference to Dr. Herman's remark,[1] I can only state that I cannot give the absolute number of cases where pregnancy has followed after the introduction of a vulcanite stem and shield; for in many instances, especially in hospital practice, we are frequently not informed of the result, and the cases under my care have been too numerous to follow to their own homes. Early in January a young woman brought her child to me at the Samaritan Hospital for advice, pregnancy having taken place after wearing a stem and shield for four months. She had been married three years and a half, previous to consulting me, without issue. I am of opinion that more sterility is due to anteflexions of the uterus than any other cause, probably more than all the other causes put together. In other displacements or flexions we often find impregnation taking place; but I cannot call to mind one single instance of impregnation occurring where an acute anteflexion existed. I will relate two typical cases. I select these for two reasons—1st, because both cases had been treated by other gynæcologists, and one by gynæcologists of both sexes; 2nd, because one was about the first case I treated in the way I am about to relate.

CASE 1.—M. R——, aged twenty-three, married between three and four years; no family. She informed me she had been attended by a lady doctor, who told her she had a tumour in the womb. She had also attended as an out-patient at St. Mary's Hospital, where she was advised to come to the Samaritan, her case having been diagnosed as displacement of the uterus. She had not menstruated before marriage, but did so soon after, with very great pain in back and left ovary, which commenced two or three days previous, and this had always been the case at the catamenial period, followed by the passing of clots, terminating in a nasty, thick, offensive discharge, and during the time was unable to get about. She also suffered great pain on connection. On examination I found her suffering from a very acute anteflexion of the uterus, into which I could only pass the sound by giving it a very considerable curve, and introducing the point downwards about three-quarters of an inch, then turning it upwards. After undergoing various methods of treatment at different times at the hospital, and wearing different kinds of stems—elastic and otherwise—without any material improvement, in July, 1874, a stem and shield, with socket to receive the button of the stem in the lower end, so as to fix the uterus in its natural position, were introduced. This she wore until November (four months), with great relief and comfort. When it was removed, she shortly after became pregnant, and is now the mother of three children. The only treatment during these four months was the syringing out of the vagina with Condy's fluid, a drachm to eight ounces of water, to prevent any disagreeable odour.

CASE 2. — Mrs. B——, aged twenty-eight, married about six years, consulted me on June 23rd, 1876. She informed me that she had suffered more or less at her catamenial period ever since she commenced to menstruate, with pains in the back and left ovary. (I cannot explain the reason why, but it is generally the left ovary that is sympathetically affected.) Since marriage all the symptoms have become aggravated, and for a day or two at the commencement of each period she is completely prostrate until she is relieved by the passing of blood clots. There is considerable leucorrhœa at all times; there is also a slight lateral curvature of the spine in the lumbar region. She stated that both her husband and herself were particularly anxious to have a family; that she had been under the care of several eminent medical men, but had failed to obtain any relief; that she had worn, amongst other instruments, a flexible india-rubber intra-uterine stem. On examination per vaginam, the body or fundus of the uterus and os were found looking (if I may so term it) towards the symphysis pubis; the mucous membrane of the vagina was inflamed, and the os uteri slightly excoriated, due to the muco-purulent discharge. A sound, a malleable one, was introduced in the same manner as in the previous case. After some preparatory treatment, on Aug. 1st an intra-uterine stem and shield were inserted, which she wore until just previous to the second menstrual period, when it was removed by my son, Mr. T. Wynn Williams of Brixton, during my temporary absence. She shortly after conceived, and was delivered of a fine girl in due course by a gentleman in Liverpool, whose name I unfortunately cannot recollect.

Montagu-square.

CASE OF SNAKE-BITE.

By F. CHARLES HEIDENSTAM, M.D.,

DISTRICT MEDICAL OFFICER OF THE LARNACA HOSPITAL, CYPRUS.

I HAD often heard that persons here in Cyprus had suffered, and that some had even died, from the venomous effects of a bite from a snake called by the natives *Kouffi* (Κοῦφυ), which is in reality the Vipera mauritanica, but I had never had the opportunity of watching or treating a case of this kind till recently, as Cypriot peasants have great faith in charms and in drugs of their own composition, which they believe to be almost infallible in cases of snake-bite, and in consequence they rarely seek medical advice.

At about 10 A.M. on 17th June, Ismail Abdullah, a Turkish zaptieh (police), aged twenty-one years, was brought to the hospital from Tohkni, a village about twenty miles distant. His story was that a snake-charmer had charmed and persuaded him that he could take hold of any snake without being bitten. Coming across one on the previous day he seized it, feeling confident that it could do him no harm, and was bitten on the back of the right hand. He felt a smarting pain of a burning character immediately he was bitten. A few hours afterwards vomiting set in, and his hand and arm became greatly swollen. On being admitted to the hospital his state was as follows:—The whole of his right hand and arm were much swollen and presented a mottled marble aspect. The marks of two punctures were plainly visible on the back of the right hand, surrounded by a dark circle a little more than an inch in diameter. On scarifying the two wounds blood of a darkish colour issued from them. The constitutional symptoms were: great prostration, profuse cold sweat, slight dyspnœa and great restlessness. Temperature 101°; pulse 116. Ammonia was administered to the patient internally, and also applied externally to the swollen arm and bitten hand. The patient was delirious and passed an exceedingly restless night.

---

[1] See THE LANCET, Jan. 1st, p. 35.

The following morning the arm and hand presented a phlegmonous erysipelatous appearance, with glandular enlargement and suppuration; dyspnœa had increased; there was diarrhœa and an appearance of jaundice. Temperature 102°, pulse 122.

During the following three days the patient's state was much the same as that on the day following his admission to the hospital. Ammonia and stimulants were continued.

On the fifth day the external aspects of the limb seemed to have improved, but high fever and restlessness continued. On feeling the arm I found that its entire length from the back of the hand to the shoulder was soft, and on making an incision above the wrist oozing matter ran from it abundantly. Similar incisions were made along the arm at three different places, the same kind of discharge made its appearance at all of them. Suppuration and sloughing continued for several days, during which antiseptic dressing was used. On July 22nd the patient had quite recovered with the exception that his arm and fingers were rather stiff.

Larnaca.

ON THE USE OF A NEW SILVER SALT IN THE TREATMENT OF ORGANIC NERVOUS DISEASE.

BY ALLAN M. LANE HAMILTON, M.D.,

ONE OF THE CONSULTING PHYSICIANS TO THE NEW YORK CITY INSANE ASYLUMS, AND TO THE HOSPITAL FOR NERVOUS DISEASES, BLACKWELL'S ISLAND, N.Y.

I HAVE no doubt my own disappointment in the use of various remedies recommended by different authorities for the treatment of organic nervous disease is shared by many who have given even the most promising a fair trial. Nitrate of silver, a drug with an ancient reputation, is one of the few not to be despised, for occasionally it proves of great service, but, as a rule, it is entirely inefficacious. We are, therefore, too apt, in a great majority of instances, to resort in a routine way to iodide of potassium, or mercurial treatment, with variable results.

About three years ago it occurred to me that the combination of phosphorus with silver might well be worth trying. I therefore, through the kindness of Dr. Doremus of Buffalo, procured a sample of the tribasic phosphate of silver, a salt prepared in the following manner:—Precipitate a solution of argentic nitrate with a solution of trisodic orthophosphate, wash with distilled water, and dry in the dark. The process may be expressed as follows:—$3NO_3Ag + PO_4Na_3,12H_2O = Ag_3PO_4 + 3NaNO_3 + 12H_2O,Ag_3,PO_4$.

A second sample of the drug was made by Mr. Frazer, of Caswell, Hazard, and Co., New York, according to the above formula. It was a heavy powder of a lemon-yellow colour, and was slightly darkened by exposure to the light.

The tribasic phosphate of silver possesses advantages over the other silver salts which entitle it to a fair trial. I have given it for months in doses varying from one-third to half a grain without any skin discoloration whatever, and its administration is unattended by the gastric irritability that so often follows the use of either the nitrate of silver or the phosphide of zinc. At the same time its therapeutical effects are much more pronounced. It is best given with some such excipients as argol and glycerine, for vegetable substances tend to decomposition; and for this reason I have discarded the confection of roses as an element of the pill mass.

In the first edition of my work upon Nervous Diseases[1] I directed attention to the probable advantages of this drug, especially in sclerosis of the posterior columns. The experience of two years has convinced me that it is my duty to urge others to make use of the remedy. In two class of cases it has proved to be of great value—1. In those of more or less acute myelitis with disturbance of the bladder and rectum. Not only in such cases of transverse disease has there been a decided improvement in the matter of control over the functions of these organs, but there has been a decided gain in the muscular power. This has been conspicuous in a very remarkable case of chronic meningo-myelitis seen in consultation with Dr. Todd of Ridgefield, Conn. 2. In cases of sclerosis of the nervous substance. In seven cases of posterior spinal sclerosis there has been a subsidence more or less in the violence of the pains, and in those who have taken the drug for over a year the power of locomotion is materially increased.

In six cases of inveterate epilepsy, as the result of gross inflammatory intracranial changes, the patients have been relieved, judging from the diminution in the number of the attacks.

I am now giving the drug to patients with cerebral tumour and general paralysis, and while it would be out of the question to expect anything like permanent cure in such hopeless diseases, I do believe that a persistent and proper use of the silver salt will do much more for the patients than any of the drugs hitherto used. I can find in medical literature no record of the use of the phosphate of silver, nor am I able to learn by inquiry that it was used prior to 1878. I sincerely hope that others may be prompted to publish their experience.

East 33rd Street, New York.

[1] Nervous Diseases: their Description, &c.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

MIDDLESEX HOSPITAL.

HYSTERICAL VOMITING OF EIGHT MONTHS' DURATION.

(Under the care of Dr. COUPLAND.)

THE following summary may be of interest in connexion with the case read by Dr. Sutherland at the last meeting of the Clinical Srciety:—

Bridget S——, aged twenty-four, a domestic servant, unmarried, was admitted on May 2nd, 1879, under Dr. Greenhow, and subsequently came under the care of Dr. Coupland. She had never been ill before, was habitually constipated, but menstruated regularly. Seven months before admission she was attacked with giddiness, faintness, and vomiting after food; she did not bring up blood at this time, but she stated that six weeks later bright blood was vomited. From that time vomiting had continued at intervals, and she suffered from continuous pain at the pit of the stomach, periodically worse every three weeks. Vomiting, which ensued immediately on taking food, always relieved the pain. The patient's appearance was certainly not that of one suffering from organic disease. She was pale, stout, and flabby, and although at first apparently suffering pain, her expression was for the most part calm and placid, and even apathetic. The pain she complained of was seated between the shoulders and in the epigastrium; there was limited tenderness in the latter region, where pressure also excited dorsal pain. Tongue was clean; bowels constipated. No other organs objectively deranged. Temperature 98·5°, pulse 88, full and regular. Urine, sp. gr. 1025, acid, no albumen. Before the evening she had vomited a large quantity of greenish fluid, neutral in reaction, containing bile. It may be added that the vomited matter was always of this character, clear (unless mixed with curdled milk or other ingesta), and of a grass-green tint, sometimes assuming an olive colour after long exposure. The vomiting proved to be the predominant symptom, recurring several times a day, but the pain and tenderness varied in intensity, in duration, and in situation. Sometimes there was nausea with or without vomiting, and very frequent attempts at vomiting. On the 20th of May Dr. Hall Davis was consulted, but the greatly contracted hymen prevented uterine examination, nor was there any reason for suspecting uterine derangement.

On admission she was put upon a diet restricted to jelly, beef-tea, and three pints of milk, all solid food being interdicted, and the milk given with lime-water. Next morning calomel and magnesia were given, which relieved the constipation that had lasted four days. On the 4th, as the food seemed to induce vomiting, nutriment was entirely administered by enemata every four hours, a few drops of laudanum being added to ensure their retention. On the 5th a sinapism was applied to the epigastrium, and on that day the vomiting was certainly less, and the pain easier, an amelioration which continued throughout the following day. On the 7th bismuth and hydrocyanic acid were prescribed, and the sinapism to epigastrium was repeated. The vomiting did not cease, although the quantity ejected was less, and on the 9th a blister was applied locally, and a small quantity of beef-tea allowed by the mouth, which was discontinued next day, as the sickness recurred violently, and hypodermic injections of morphia (one-sixth of a grain) were commenced. On the 11th she was allowed a little egg and brandy by the mouth, and the carbonate of bismuth given in place of the liquor. There was no abatement of the vomiting however, and the nutrient enemata were still continued. On the 13th ice caused pain, and vomiting still persisted. Oxalate of cerium was prescribed on the 14th, and on the 15th she was free from sickness for twenty-four hours, but under the same treatment the vomiting recommenced on the 16th.

From May 18th to June 8th the vomiting still continued, and the quantity of vomited matter was compared with the amount of urine excreted every twenty-four hours—viz. :

	Vomited matter.	Urine.	Bowels.

* Passed under her.

The treatment during this period varied as much as before, the chief measure being hypodermic injections of morphia ($\frac{1}{6}$ gr.), and atropia ($\frac{1}{120}$ gr.) every six hours, until the 5th of June, when they were finally discontinued; ice was applied to the epigastrium on May 24th, and an ice-bag to the spine on the 29th. On the 25th some fish and jelly were given by the mouth, the enemata still being continued. Most of this food was retained; and on the 2nd of June it was decided to discontinue the rectal alimentation entirely, especially as it was likely that, after a course of four weeks' uninterrupted administration, the absorbent power of the mucous membrane must have been somewhat exhausted. The fish diet, with beef-tea, milk, and an egg, was therefore given on the 2nd, with the addition of custard-pudding on the 5th, when also the hypodermic injections were left off. The result of this change in treatment proved very satisfactory. On the 8th only two ounces were vomited, and from that date the sickness ceased. She was allowed to get up, encouraged to exert herself, having during the whole time lain in an apathetic inert condition. Meat was allowed on the 10th, and she had no return of pain. Throughout the temperature had been normal or subnormal, and the pulse rate from 84 to 96. The urine was free from abnormal constituents. The patient left the hospital on June 27th.

Remarks.—In spite of the resemblance of the symptoms to those of chronic gastric ulcer, which led to the measures employed in the first instance, it became obvious after a time that the vomiting was of a neurosal character. The aspect and well-nourished condition of the patient, the occurrence of vomiting independently of taking food (even when no food was taken by mouth); the character of the vomited matters, from first to last free from blood; and the act of vomiting itself—all combined to favour the hysterical hypothesis. Indeed, it could hardly be called vomiting; it was often little more than a simple regurgitation or fluid eructation, not accompanied or preceded by straining, or notable contraction of the diaphragm or abdominal muscles. A note made on May 22nd illustrates this point:—"Pressure over the epigastrium causes a sense of nausea, and at times even actual sickness. Whilst the abdomen is being palpated very gently, without manifest pain, some clear fluid is ejected from the mouth without any effort or the usual mechanism of vomiting being brought into play." The result of allowing her solid food, of calling into play her dormant volition, and of ceasing to regard herself as an incurable invalid, seem to place the purely functional character of the affection beyond a doubt. At the Clinical Society last year Dr. Graily Hewitt recorded a remarkable case where vomiting had continued persistently for ten months, unalleviated by all measures of treatment. The patient was reduced to an extreme degree of emaciation, and the vomiting ceased after measures had been taken to rectify a malposition of the uterus. In the present case there was no evidence of any uterine derangement, and, in spite of vomiting (which before admission had occurred intermittently for some months), her general nutrition was unaltered.

COUNTY HOSPITAL, LINCOLN.

GUNSHOT INJURY; DESTRUCTION OF RIGHT KNEE-JOINT AND AMPUTATION OF THIGH; ANEURISM OF LEFT FEMORAL ARTERY TREATED BY DIGITAL PRESSURE AND ESMARCH'S BANDAGE.

(Under the care of Mr. SYMPSON.)

FOR the following notes we are indebted to Mr. W. J. Cant, house-surgeon.

J. T——, aged forty-six, was admitted on August 22nd, 1880, with a severe gunshot injury of right knee, left thigh, and both hands, caused by the discharge of a fowling-piece at a distance of about twenty feet. The tissues were not much torn, but there were marks indicating the entrance of numerous shots. The patient suffered from severe shock, soon followed by well-marked inflammatory reaction. The knee-joint was poulticed and fixed immovably on a McIntyre splint. Both hands, after suppurating freely, gradually healed. Numerous abscesses formed round the knee-joint, which were opened, allowing the escape of large quantities of laudable pus. The temperature was always more or less above normal, and on two or three occasions reached as high as 103°. There was continuous intense pain, radiating from the knee-joint, with increasing formation of pus, which discharged from numerous sinuses. Symptoms of exhaustion were setting in. On Oct. 2nd a consultation was held, when it was decided that the thigh should be removed at the junction of the middle and lower thirds.

On opening the knee-joint after its removal it was found to be extensively damaged, the cartilage over the head of the tibia was torn and ulcerating; both condyles of the femur were denuded of cartilage, and the cancellous tissue was broken up. The operation was performed under the antiseptic treatment.

On the day before the operation a small pulsating swelling was found connected with the femoral artery of the left thigh, which, on careful examination, was proved to be an aneurism. The tumour was rapidly increasing, and on Oct. 3rd, was found to have reached the size of a small orange. At two o'clock of the same day digital compression of the femoral artery at Scarpa's triangle was commenced and continued for two hours, when Esmarch's bandage was applied from the toes up to the aneurism, and then to the thigh above the aneurism, thus leaving the tumour exposed. Digital compression was continued, as the pressure from the Esmarch's bandage was not sufficient to stop the pulsations (ether was not administered). The bandage and pressure were continued for eight hours, when on their removal the pulsations had ceased, and the tumour consolidated.

The thigh-stump healed completely in about three weeks, without any formation of pus, showing a firm and linear scar. The aneurism gradually diminished in size, and on Nov. 8th, when the patient was discharged cured, scarcely anything could be felt of it; the femoral artery pulsated above and below the tumour.

CUNNINGHAM HOSPITAL, ST. KITTS, WEST INDIES.

CASE OF ELEPHANTIASIS OF THE LEG; AMPUTATION; SECONDARY HÆMORRHAGE ON THE TWENTIETH DAY; LIGATURE OF FEMORAL ARTERY; DEATH.

(Under the care of Mr. A. BOON.)

S. G——, a delicate-looking negro labourer, forty-five years of age, was admitted into hospital on Oct. 27th, with elephantiasis, and an extensive ulcer of the left leg. The elephantiasis extended up to the knee, and slightly above it; the ulcer occupied the lower third of the leg; it was deep and foul, discharging profusely, and of many years' duration. The right leg was not affected. Urine normal. Had had syphilis and dysentery several times. As the ulcer was very large and incurable, and therefore a great drain on his strength, and as his general health was better than it had been for some time, it was determined to amputate, which was accordingly done on the 30th, by the circular method, the bones being sawn through at a line about one inch below the tuberosity of the tibia. The elastic tourniquet, on being applied before the operation, broke, the india-rubber having been spoiled by the climate, so an ordinary tourniquet was put on. The venous hæmorrhage was pretty severe, which is often the case; several large veins and about a dozen arteries required ligature. The stump was swabbed with a solution of chloride of zinc, and enveloped in carbolised tow. Carbolised catgut ligatures and horse-hair sutures were used. After the operation all went well. By the end of the first week the flap had united, except at two points. At first there was the profuse watery discharge that is always seen in such cases; afterwards a small quantity of inodorous pus was found on the dressing which was renewed every two or three days. The patient's general health improved steadily; his temperature and pulse remained at normal; his appetite good; his bowels regular; his sleep unbroken. So things progressed; he was far in advance of a man in the next bed, whose leg had been removed a week before his for traumatic gangrene of the foot.

On the evening of the twentieth day the patient foolishly got out of bed on to the floor: frightful hæmorrhage came on; the alarm was given, and the resident assistant, Mr. Winter, was speedily on the spot and applied a tourniquet, which effectually controlled the bleeding, but in the few minutes several pounds of blood had been lost. Mr. Boon was sent for, and on his arrival found the man in a state of collapse. Stimulants were given, and he rallied to some extent. Mr. Boon then, with the assistance of Dr. Waldron, opened up the flaps, which were very firmly united except at the two points mentioned above, and sought for the vessel from which the hæmorrhage had come, but was unable to find it; the man was in such a condition that it was not safe to relax the tourniquet. It was, therefore, decided to tie the femoral artery in Hunter's canal, which was done. Though the vessel was empty, in consequence of the tourniquet being still on the limb, and the operation had to be done by lamp-light, there was not much difficulty in finding the vessel and applying the ligature. But the loss of blood had been too great, and the patient died shortly after.

The next day a careful dissection showed that the hæmorrhage had come from the popliteal artery; the vessel tapered a little at the cut end, which was patent, the diameter of the opening being equal to about one-third of that of the vessel. It was evident that the catgut had behaved much in the same manner as an ordinary silk ligature. The artery itself seemed to be healthy except at a point about one-fourth of an inch from its extremity, where there was an irregular opening of about the same area as the one already mentioned, which had the appearance of being the result of an ulcerative process in the coats of the vessel. Finally, there was merely a slight trace of an internal plug, a few shreds of blood-stained tissue adhering to the sides of the vessel and in no way obstructing its calibre.

Remarks by Mr. BOON.—Though the questions of the advisability of operating, and the method of operation, in such cases of elephantiasis may be discussed at another time, this case is of interest from the fact that the carbolised catgut ligature was used, and secondary hæmorrhage ensued at an unusually late date. I am satisfied, however, that there was no connexion between the form of ligature and the hæmorrhage. No doubt the patient getting out of bed was the immediate cause of the catastrophe, but I am inclined to think that, sooner or later, the vessel would have given way. It is not so clear what was the cause of the almost complete absence of the internal plug. Probably the syphilis, the hæmorrhage at the operation, and the general condition of the patient, all three, had something to do with it. I may add that the carbolised catgut was above suspicion, having been procured from Weiss.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Congenital Truncation of Forearm.—Tubercular Disease of Joints.—Abscess in the Liver.

THE ordinary meeting of the Pathological Society of London was held on Tuesday, Feb. 15th, Dr. Wilks, President, in the chair. The chief subject considered was the presence and influence of tubercular growths in the synovial membrane and bones of diseased joints, introduced by Mr. Croft and illustrated by microscopical preparations by Drs. Greenfield and Mercer and Mr. Makins. Dr. Andrew Clark brought forward a case of Abscess of the Liver which presented features of considerable interest.

Mr. BARWELL showed two living specimens of Truncated Malformation of the Forearm. This deformity has latterly been considered to be due to intra-uterine amputation by shreds of indurated fibrin. No doubt intra-uterine amputation does occur, for in some few rare cases the amputated portions have been born. He had found of such cases only three on record—in one, the foot was amputated and born afterwards; a second, in which the foot was born hanging to the amputating thread; and a third, in which the foot was born some days before the child. Simpson speaks of the little finger-like growths at the end of the stump as the results of secondary reproduction. Both the women shown had a truncated forearm; the younger one has four small digits and a little depressed pucker; the elder one has four fingers and thumb and a palm, all rudimentary; no pucker; no nails in either case. There is considerable voluntary movement of adduction and rotation of these fingers as a whole. We cannot believe that these muscles and nerves are formed by rudimentary reproduction, and, therefore, in most of these cases the theory of intra-uterine amputation also falls to the ground. Most of these cases are really lack of development. He had seen many cases, and in all of them but one there had been rudiments of fingers.—Dr. N. MOORE thought the view of arrested development fully borne out by facts. These cases were most interesting in comparison with the sirenia—aquatic herbivora—in which the hind-limbs are not developed; these animals are probably descended from terrestrial herbivorous animals, with perfect hind-limbs. In all the instances of undoubted reproduction of amputated limbs, as in amphibia, the new limbs are perfect.—Dr. WILTSHIRE bore testimony to the accuracy of Mr. Barwell's statements. He had never seen a case of true intra-uterine amputation. The rudimentary digits in the cases shown were of the size of a fœtus of four months, and this fact suggested that the developmental error occurred at that time. Cretinoid fœtuses show well a condition of truncated arms and legs, which, if carried further, would simulate Mr. Barwell's cases. It is an arrest of development, and very rarely amputation.

Mr. CROFT showed a series of microscopic specimens to illustrate the occurrence of Tubercle in Bone and Synovial Membrane. He premised that by tubercle he meant a small-celled growth surrounding epithelioid cells, with giant cells, and a fine reticulum, non-vascular, and tending to caseation in its older forms. The patients from whom the specimens were obtained were all in delicate health; their joints progressed very tediously; there was great hyperplasia, and abscesses with carious pus. Case 1, aged twenty, had effusion in knee-joint for three months; the leg was amputated; tuberculosis of synovial membrane was found; he subsequently died of intestinal phthisis; his grandparents had been phthisical. Then followed three cases of chronic hip disease, aged four, six, and twelve, who had suffered for six months, one year, and two years. One died from tubercular meningitis, another died of rapid general tuberculosis. The near relatives of two of them were consumptive. Case 5, female, aged twenty, disease of knee two years; died after excision. There was tubercle of lungs and spleen. Case 6, girl, aged eight, chronic disease of ankle more than three years; the grandparents were consumptive. The microscopic examination had been conducted by Dr. Clifford Mercer, under the direction of Dr. Greenfield, to both of whom he was greatly indebted. Dr. Greenfield had drawn up a report, which was as follows :—

CASE 1. P——. (Knee-joint.)—*First series of sections, through the semilunar cartilage and a mass of fungating granulations* growing from it. The outline of the fibrocartilage is distinct at the lower part, and its structure there appears unaltered. On the upper surface is a mass of granulation tissue more than half an inch in thickness, from the edges and surface of which project vegetations, some of which are polypoid. The upper layers of the fibro-cartilage show some signs of inflammation, and the fibres are separated by rows of leucocytes. Continuous with this surface is a layer of granulation tissue of ordinary character, which resembles in every respect organising cicatricial tissue, and contains vessels of new formation. This layer of granulation tissue is about half an inch thick, and forms by far the larger proportion of the thickened mass; towards the surface it becomes somewhat more cellular in structure. Completely covering it, both on the surface and at the edges, and penetrating for a short distance between the granulation tissue and the fibro-cartilage near the free edge of the latter, is a layer of tissue of entirely different structure, and abruptly defined. This has the structure usually seen in rapidly caseating tubercular infiltrations. This layer has the following characters. At the surface it consists of amorphous granular material, contains a few nuclei and the remains of cells (caseating mass). At the deeper surface, where in contact with the granulation tissue, it is limited by a more or less uniform and dense layer of small round cells, which stain deeply with reagents (leucocytes). In the intermediate layer are seen all grades of rapidly growing and degenerating tubercular granulations. These are, as usual, made up by the aggregation of small rounded or ovoid masses (tubercle follicles), united by a more or less perfect adenoid tissue. Only very few of the tubercle follicles present the perfectly developed typical form. These have the usual characters of one or more multi-nucleated cells (giant cells), with branching protoplasmic processes, which are continuous with a reticulum, formed mainly by branching flattened endothelial cells, and containing in the interstices rounded, ovoid, or variously shaped cells with relatively voluminous protoplasm. In many the reticulum is indistinct, or only seen here and there. They consist of one or two, or more, giant cells, spheroidal or polygonal cells, and spindle cells, especially at the periphery, all massed together. In others two or three enormous giant cells form the greater part of the mass. Caseation is common at an early stage, and fibrous change is rare. The caseated follicles have the usual appearance—an amorphous central mass, containing sometimes the remains of a persistent giant cell, towards the edge ovoid or elongated nuclei running outwards and merging in the tissue around. In some parts of the mass, and especially in torn edges, there are seen, as composing the growth, many large spheroidal or polygonal cells with a single or double nucleus (so-called epithelioid cells), many large spindle cells with ovoid nuclei, and large multinucleated cells. In fact, in all its characters this layer is identical in appearance with a layer of tubercular infiltration of the peritoneum, or of any organ. Scarcely any capillaries are visible in this layer of the granulations; it is almost entirely non-vascular.—*Second series of sections, through the edge of the articular cartilage and the bone*, and a mass of vegetating granulations at the free margin. The bone and articular cartilage show no marked change. The structure of the vegetations is identical with that seen in the first series of sections, the deeper layers being ordinary granulation tissue, the more superficial consisting of imperfectly formed tubercular granulations. In some places the synovial membrane is continuous over the layer of tubercle, and appears but little altered.

CASE 2.—W. R.—(*a*). *Sections of thickened synovial membrane.*—The thickened membrane formed a mass about a quarter of an inch in thickness, nearly smooth on the surface. In this could be distinguished a thin deep layer, consisting of the remains of the synovial membrane and ordinary granulation tissue, and a superficial, somewhat dense layer of caseous material; but by far the greater part is composed entirely of a mass of tubercular granulations. These are extremely typical, the follicles being very well developed, the giant cells and reticulum large and prominent. There is scarcely any caseation except at the surface, and the growth of the tubercle is orderly and apparently gradual. In the intermediate tissue between the tubercle follicles a relatively large proportion of newly formed vessels is seen, and towards the caseating superficial layer these gradually become blocked by concentric proliferation of their walls, which are entirely cellular. (*b*). *Sections of bone from the head of the femur, near the epiphysis.* (*c*). *Perpendicular sections of the bone after softening in chromic and hydrochloric acid.* A few grey granulations are visible with the naked eye in the sections, near the surface. Microscopically, they present the same characters as the tubercle in the synovial membrane; they are entirely situated in the medullary tissue—i.e., they do not appear to affect the bony trabeculæ.

CASE 3.—F. R—— (Mr. MacCormac's case.)—(1) *Sections through articular cartilage of the head of the femur, and a cauliflower-like mass of vegetations on its surface and projecting at the edge* (these formed a ring at the margin of the cartilage). The cartilage itself is but little altered, except some small cavities filled with granulation tissue. The chief substance of the vegetations is composed of granulation tissue. At the surface a condition closely resembling that in Case 1 (P——), viz., superficial caseation, and a layer composed of imperfectly formed tubercular granulations. Here, however, they are even less perfectly formed, and caseation is more advanced. Many consist merely of masses of epithelioid cells varying much in size and shape, contained in an ovoid or rounded cavity formed by imperfect lymphoid tissue. Only a few contain giant cells fully formed, or a complete reticulum. (2) *Sections of bone* from the head of the femur show no tubercle.

CASE 4.—Harriett P—— (knee-joint), 1 and 2. *Two series of sections from thickened synovial membrane.* In one series there is a deep layer of fat which is unaffected. In other respects the two series show very similar changes. The fibrous layers are swollen and show ordinary inflammatory changes, and upon the surface is a layer of ordinary vascular granulation tissue. Here and there in this layer are seen isolated tubercle follicles. Superficial to this is a layer of much greater, though variable thickness, consisting of ordinary tubercular infiltration. Upon the surface of this is a caseous layer of variable thickness. It is not easy in all parts to distinguish the tubercular zone from the zone of ordinary granulation tissue, the two seeming to shade off into one another in some parts, or the tubercle follicles to be embedded in the layer of granulation tissue. But in the completely formed tubercular zone the structure is very perfectly developed.

CASE 5.—Florence W—— (ankle-joint).—1. *Sections of a rounded mass of swollen synovial tissue*, consisting largely of fibrous bands. Owing to imperfect preservation the structure is not well brought out, but there is apparently an infiltration of the tissue with tubercle. In some parts the tubercular structure is very clearly seen.

CASE 6.—Lizzie F—— (hip-joint).—1. *Bone.*—The sections are from the head of the femur in the same position as in Case 3, and they show a similar condition—viz., the presence of scattered tubercular granulations—very few in number, and best seen near the surface of the bone. The periosteum over the part where it remains shows merely inflammatory thickening. 2. *Synovial membrane.*—No tubercle was found in any of the sections of the small piece examined.

CASE 7.—Hector W—— (hip-joint).—*Sections apparently of the round ligament, which is somewhat irregularly swollen.*—These sections consist entirely of ordinary newly formed young connective tissue, which is highly vascular, and in many places of myxomatous type.

Summary.—It appears from a comparative examination of these specimens from the hip, knee, and ankle joints, that in all the six in which the synovial membrane and bone were examined, tubercle was found; whilst in one in which only the thickened round ligament was examined, no tubercle was present. In the thickened synovial membrane a combination of common inflammatory changes with tubercular infiltration is present, and usually three zones may be distinguished: 1, a superficial caseous zone; 2, a zone of tubercular infiltration, usually forming a large proportion of the entire mass; and 3, a zone consisting of the fibrous structures of the synovial membrane in a state of chronic inflammation. In the latter zone, as well as in the bone, isolated tubercular granulations are seen. In the articular cartilage in these cases nothing beyond some spaces filled with granulation tissue was seen. It is, of course, often a question whether the fungating mass examined is synovial membrane or newly formed fibrous bands, as the structure of the synovial membrane, if present, is quite obscured. I have not hesitated to call the structure in all these cases "tubercular" on the ground that it is identical with that seen in tuberculosis in whatever organ it may be examined, and that microscopically it is indistinguishable from tubercular infiltration of a serous membrane, whilst it is entirely distinct from the ordinary products of inflammation, whether acute or chronic. With regard to the majority of the specimens, those in which the growth is made up of rounded masses, themselves in turn composed of grouped follicles in which the structure of tubercle—giant cells, reticulum of flattened epithelioid cells, &c.—can be distinguished, I suppose there will be little doubt. But, in the other cases, where although the structure is similarly arranged, the follicles contain giant cells and epithelioid cells, without definite visible arrangement of reticulated stroma, there may be some who would prefer to call the change scrofulous inflammation. I have adhered to the term tubercle for these reasons. 1. That the same structure is met with in the rapid growth of tubercle elsewhere—it appears, in fact, to be a question of completeness of organisation before caseation occurs. 2. That a like condition is found in some parts of nearly all tubercular infiltrations in other organs, and is especially common in some—e.g., the spleen and liver. 3. That in the specimens where there are the most typical tubercular granulations this condition also occurs in many places. 4. That in other respects these specimens are precisely similar to the unquestionably tubercular, differing only in more rapid caseation. Additional evidence in favour of this view is found in the fact that in Case 3, where this imperfect organisation was most apparent, there was the most extensive tuberculosis of other organs, including tubercular tumour of the cerebellum and tubercular meningitis, and tubercle in lungs, liver, kidneys, and peritoneum.

Mr. CROFT considered that these cases raised seven points of interest. First, he thought there could be no doubt that the changes were really tubercular, and not simply inflammatory. Then, although it was impossible to be certain whether the tubercular affection was primary, and not preceded by any simple inflammation, he inclined to the opinion that there was some primary simple inflammation followed quickly—how quickly he could not tell—by tubercular growths. As to the question of infection from caseous deposits, in five out of the six cases there was no reason to think any caseous deposits pre-existed, but the joint lesion was really primary; but in the sixth it may be presumed that some caseous calcified mediastinal glands were of older date than the joint trouble, which was of two years' standing. Three died from general tuberculosis, suggesting systemic infection from foci in the joints. Again, if tubercle be non-vascular, and incapable of organisation, does not its presence constitute a strong argument for early removal of the diseased tissues? Quoting Volkmann, Köster, Cornil and Ranvier, Wilks and Moxon, in his support, he urged that there is a class of cases characterised by primary tubercular disease of the synovial membrane. In approaching the larger question of the existence of a true primary tubercular arthritis and its frequency, he quoted Erichsen, Holmes, and Bryant, as expressing the common view of English surgeons, that if ever found it is very unusual; and König, Bidder, Billroth, and Volkmann, as maintaining its great frequency. He hoped that further investigation would clear up this discrepancy, and strongly urged the importance of careful microscopic examination in all cases of excision for chronic joint disease.

Mr. MAKINS showed specimens of a case of Tubercle of Synovial Membrane from the Elbow-joint. The man had no history of tubercle or signs of tubercle elsewhere, and no affection of bone. The sinuses left since the excision are apparently affected in a similar manner.—Dr. D. POWELL asked if there was anything known of the family history, and whether there was any history of injury.—Mr. MAKINS could not find any trace of phthisis in the family, and there was no history of injury in the case.—Dr. POWELL said Mr. Croft's cases showed the effect of injury in determining the disease in certain positions, in the same way as gout or rheumatism might be localised. Other cases show the effects of disease of bone in setting up general miliary tuberculosis. Primary miliary tuberculosis of one joint was certainly a most striking fact, and required a very great deal of evidence in its support. None can doubt that the cases shown are really tubercular.—Mr. BRYANT could not deny that these cases are really tubercular; but was the disease in its origin tubercular? for, surely, the existence of tubercle in bones and synovial membrane is very rare. He had seen tubercle in synovial membrane with the same affection elsewhere, and these cases showed no special clinical symptoms. He thought that in these cases the tubercle was part of a general affection, and secondary to some earlier chronic inflammatory disease. A large number of old cases of joint-disease die from general tuberculosis or tubercular meningitis. He thought we ought not to set up a separate variety of diseases of joints tubercular in their origin.—Mr. GODLEE asked if in any number of cases of supposed tubercular nature these special structures had always been found; and in cases not supposed to be tubercular whether they had been present. In his examination of the granulation tissue of a joint, contributed to the Pathological Society in 1877, he did not meet with any signs of tubercular follicles, and he still adhered to his former hypothesis that the changes seen are merely a phase in the organisation of chronic inflammatory tissue.—Mr. BARWELL thought we ought to be careful in distinguishing tubercle of bone and synovial membrane from tubercle of inflammatory products. Many cases of disease of joints result from injury, they are very chronic, and in some there are caseous patches, but it is doubtful whether these are really tubercular. He did not think that tubercle of bone proper exists.—Mr. MACNAMARA, after repeated examinations, had found tubercle in a great number of cases in the cancellous ends of bones. He had found a tissue precisely the same as that called tubercle elsewhere, and especially in the synovial membrane of the ankle-joint. In cases of joint disease with continued high temperature, there is tubercle which will eventually infect the other parts of the body. The disease is most often set up in the soft tissues between the epiphysis and diaphysis, frequently from injury; but tubercle may occur primarily in the synovial membrane; most of these cases occur in members of tubercular families.—Mr. TREVES thought the specimens of bone were not conclusively tubercular, the giant cells there seen were not characteristic of tubercle. But the changes shown in the synovial membrane were undoubtedly true tubercles. He doubted whether Mr. Croft had made out his case in regard to bone.—Mr. CROFT had purposely omitted reference to the clinical symptoms of tubercular disease of joints, for we must first decide whether such a disease really exists. Mr. Bryant's cases had not been examined microscopically, and it must be remembered that what appear to be grey granulations seen with the naked eye may not be tubercle, and tubercle when present may not be seen without microscopic examination. The question really is what is the relation between tubercle and inflammation of joints? Can simple caseous degeneration give rise to tubercle? It was not one, but the collection of several characters that indicate tubercle. He was glad to have Mr. Macnamara's support, as he had made careful microscopical examinations. Only these six cases had been examined. In one other case the round ligament only of the hip-joint was examined, but was not tubercular, though expected to be so from its naked eye appearance.

Dr. ANDREW CLARK brought forward a specimen of Abscess of the Liver, which was of clinical rather than pathological interest. A man, aged forty, admitted into the London Hospital in November last, died in January. Good personal and family history; perfect health up to June, 1880. Then after leaving Calcutta he lost flesh and strength, and was feverish. At Durban an enlarged liver was detected. On admission Dr. Clark found nothing definite, and the liver smaller than natural; not tender. Other organs normal. He presumed he had matter somewhere, and probably about the liver. At his next visit he found a dry friction sound over base of right lung. He aspirated from the axilla from right to left, and after some trouble twelve ounces of purilage was extracted. For a week the man improved, but then he failed again. The liver dulness rose in front to nipple line, and higher behind. The base of lung was consolidated. The abscess was again aspirated from the front two or three times without finding the pus. The man speedily died. A few days after the first aspiration the man coughed up a few pellets of purilage, containing bile pigment and elastic fibres. At the post-mortem the liver was found to contain a large abscess in the right lobe passing up as high as the root of the right lung, and many other small abscesses nestled in the liver. The colon was ulcerated in the cæcum and ascending colon, the ulcers being older below than above, but none of them of long duration apparently. Possibly the material of any causative emboli did not come from the ulcers. When the liver is small, and there are no tender spots, it is well to aspirate from right to left, as the abscess is in that way more likely to be reached. Friction is not a sign of adhesion of the two surfaces of a serous membrane. The abscess ought to have been opened at once when the fact of an abscess was once shown.—Dr. GREENFIELD asked if there was any displacement of the heart's apex, as that sign had assisted him to recognise an hepatic abscess spreading upwards. Were there any rigors after the first aspiration?—Dr. CLARK: The apex beat was normal. Fresh imperfect rigors and profuse sweats with irregular pyrexia occurred after the first tapping.

The Society then adjourned.

CLINICAL SOCIETY OF LONDON.

Chronic Vomiting treated by Koumiss.—Gangrene of Arm from a Poisoned Wound; Amputation of Shoulder.—Sarcoma of Dura Mater, encroaching on left Temporo-Sphenoidal Lobe of Brain.

THE ordinary meeting of this Society was held on the 11th inst., Professor Lister, F.R.S., President, in the chair.

Dr. H. SUTHERLAND brought forward a case of Chronic Vomiting, in which no food was taken, except koumiss, for eighteen months. The patient, a girl, aged twenty-four, on admission had been for five years under his care at the St. George's Hanover-square Dispensary. The vomiting commenced one year and nine months ago, the attacks coming on at first only once a fortnight, but lately they had occurred always once, and sometimes five or six times a day. As far as could be ascertained there was no organic disease of the stomach, no tenderness on pressure, or cachexia, nor any other constitutional symptoms. Every known remedy was tried to allay the vomiting—bismuth, opium, hydrocyanic acid, creasote, carbolic acid, hyposulphites—all without any satisfactory result. All attempts to cure the case by dieting had failed, and the patient could keep nothing on the stomach, as food, except koumiss, which she had taken for sixteen months. She is, however, able to retain a quinine and orange mixture, and also sherry in small quantities; but brandy makes her sick immediately. The uterus was not displaced. The object in bringing the case before the Society was to ask if any member could suggest any remedies or mode of treatment in this distressing case. — Dr. JAGIELSKI had found koumiss of value in cases of intractable dyspepsia, improving the digestive organs, as well as allowing them rest from other food. Dr. Sutherland's case was, however, quite unique. He had never read of a case where koumiss was the only article of diet for eighteen months. The patient, too, would seem to have increased in weight, and the cause of the rejection of all other food was an interesting matter. Some cases of this nature do well on other remedies and on concentrated foods—e.g., where vomiting has continued for several days, especially when pure milk is rejected, buttermilk, sour milk, or whey can be retained. He was inclined to think that koumiss was best retained because it has undergone a double fermentation, the lactic and the alcoholic, and the casein, therefore, probably is intimately intermingled with carbonic acid, which would render it more easily capable of assimilation. The most difficult case he had had to treat by this means was one of phthisis; but the good state of nutrition of Dr. Sutherland's patient was most surprising.—Dr. BROADBENT said the case was interesting as showing that apparent health and good condition could be kept up on a diet of koumiss alone, and he asked what amount of work the patient did during the time. The case appeared to have all the characters of hysterical vomiting, and other features of the case, the mental irregularities, &c., pointed to the hysterical condition, by which he did not, of course, imply that hysteria meant mendacity, and she may have lived on koumiss. The case might be compared with the instances of "fasting girls" and such like.—Dr. ROBINSON inquired whether any local treatment, such as blistering to the epigastrium, had been employed.—Dr. W. ROGERS agreed with Dr. Broadbent's view of the case, and asked what were the mental states of the patient, and thought the uterus might be at fault. He had seen many cases of persistent vomiting due to uterine derangement.—Dr. B. O'CONNOR had a similar case under treatment for the last four months, and finally applied nitrate of silver to the os uteri, on the ground of the stated efficacy of that measure in the vomiting of pregnancy. The vomiting ceased, but afterwards returned. Milk diet gave no benefit, but cream was retained better, and small doses of Valentin's extract of meat. Dr. Sutherland's case pointed to pulmonary and uterine conditions being the cause of the vomiting.—Dr. WILBERFORCE SMITH asked as to the diet presented before the koumiss was resorted to. Success was best obtained by abstaining from nitrogenous food, and thus giving physiological rest to the stomach. This principle applied to organic disease of the stomach as well as vomiting of nervous origin. In such cases he had found cream and fatty foods retained, and also the essences of meat, which were devoid of nitrogenous material; or entire rest might be maintained by nutrient enemata. He mentioned a case of chronic ulcer, with dilatation, seen with Dr. Fenwick, in which this line of treatment was successful.—Dr. DOWSE asked how much koumiss was taken in the twenty-four hours. He thought the vomiting was of nervous origin, due to inhibition of the vagus; and suggested that fluid nutriment should be given up and the patient fed on solids for twenty-four or forty-eight hours.—Dr. SUTHERLAND, in reply, said that goat's milk, sour milk, and buttermilk had been tried unavailingly. The patient does no work, but is not confined to bed. She is sometimes very melancholic and sensitive, but not hysterical. He would try Valentin's extract, but nutrient enemata were of no use, and he did not think solid food would be retained. She took two pints of koumiss daily. He had not tried blistering to the epigastrium.

Mr. CHRISTOPHER HEATH narrated a case of Gangrene of the Arm from a Poisoned Wound, amputation at the shoulder, and recovery. The patient was a nurse, aged thirty-four, who, in laying out the body of a lady who had died of puerperal septicæmia, pricked her thumb with a pin. Notes of the puerperal case were given by the physician who had attended her, and it appeared that she was a primipara in good health, and was the first patient attended by the accoucheur after his holiday, and that strict antiseptic precautions were employed. On the fourth day a rigor occurred, and the temperature was 105°; pulse 120. Subsequently the temperature went up to 107°, but was reduced to 102° by an ice-cap and cold-water bed. On the seventh day, however, the left pleura filled, and the patient sank. A nurse in attendance pricked her finger on the day of the rigor, and had a sharp attack of lymphangitis with recovery. The second nurse carried out the attendance till the patient's death. This nurse applied nitrate of silver to the puncture on the evening of the day she received it, and the next day the hand was swollen and painful. She had no further advice until the fourth day, when she was admitted to University College Hospital with the whole arm swollen and tense. Free incisions were made, but the next day the hand and forearm had gangrened. At first the gangrene seemed limited to the forearm, and the swelling of the upper arm decreased for a few hours; but a relapse taking place Mr. Heath amputated at the shoulder-joint. The patient made a rapid recovery, and was discharged in a month. Mr. Heath remarked upon the virulence of the puerperal poison, and protested against the common practice of applying nitrate of silver to punctures received at post-mortem examinations. He believed that the application of belladonna was most useful in cases of local inflammation, coupled with free incisions, when necessary.—Mr. CRIPPS related the particulars of a similar case lately under Mr. Holden's care at St. Bartholomew's Hospital. A healthy, temperate man pricked his finger with gorse three days before admission. The thumb became swollen and painful, and the back of the hand œdematous. When seen the hand was black, and there was swelling half-way up the forearm. Free incisions were made into the palm and back of the hand, and a small quantity of thick-clotted blood and serum escaped. Two days later the swelling increased; but after consultation amputation was deferred for twenty-four hours. At the end of that time the swelling had greatly extended, and Mr. Holden amputated at the shoulder-joint, through tissues already inflamed and swollen. Antiseptic precautions were taken, and the temperature fell from 103° to 99°. The patient improved for four or five days, but at the end of the sixth day he had a rigor, and the œdema extended to the neck. Incisions were small, but the cellulitis spread; the side of the face became black and gangrenous, and death ensued. Mr. Heath's case showed the advantage of early interference, and Mr. Cripps thought there should be more definite rules in surgery as to the indications for such interference.—The PRESIDENT said these cases confirmed the old surgical rule that, in spreading gangrene, amputation should be performed without delay. It was done in time in Mr. Heath's case, but not in Mr. Holden's. Koch's researches had shown that the condition depended on some organism. They proved that there were some organisms which produced a real blood disease—as the bacillus anthracis; others which caused septicæmia in a mouse; and another well-marked organism (occurring in chaplet-like rows), producing spreading gangrene—a progressive necrosis without general blood infection. Evidently in these cases the organism was one which tended to produce such local mischief rather than general.—Mr. HEATH said the rule of procedure was not only to amputate early in such cases, but also *high up*. The gangrene would spread in such cases as these unless the surgeon were prepared to amputate at the shoulder at once, without waiting for consultation, which deferred action.

Dr. WHIPHAM then read a case of small, Round-celled Sarcoma of the Dura Mater, encroaching on the left temporo-sphenoidal lobe of the brain, and producing extensive softening in its neighbourhood. A railway guard, aged thirty-five, was admitted into St. George's Hospital on January 25th, 1880. He had served on board ship in former years, and when in foreign parts had suffered from ague, dysentery, and acute rheumatism. At the end of December, 1879, he caught cold, had rigors and pain in the chest, and dyspnœa, but continued his occupation as a railway guard. During the fortnight previous to his admission he had been laid up with headache in the frontal region. About thirteen days before he came under observation he felt unwell, and became languid, and on the day following he shivered and felt pain in the frontal and temporal regions. The pain recurred in severe paroxysms with intervals of entire cessation of pain. On admission, the patient was well nourished, but somewhat dull and stupid; his tongue was coated; pulse 72, small; he had severe headache, and said he felt "stuffy in the head." The pain was referred to the left temporal region and to the left eye. There was a purulent discharge from the right ear, and Mr. Dalby reported a large perforation of the tympanic membrane. Shortly afterwards the patient became restless at night, and on the seventeenth day after his admission had passed into a comatose state, but still indicated by gestures that he was suffering pain on the left side of his head. Slight want of power in the right hand and leg was detected, but there was no real paralysis. The patient died on Feb. 24th. He was a left-handed man. At the post-mortem examination a lobulated tumour was found attached firmly to the middle fossa of the skull on the left side, and extended into the substance of the left temporo-sphenoidal lobe of the brain, involving or causing softening of the anterior parts of the three temporo-sphenoidal convolutions and the island of Reil. The softening extended to within one-twentieth of an inch of the level of the upper surface of the corpus striatum, but did not involve that ganglion. The important feature in the case was its bearing on the question of localisation of the functions of the brain. Although none of the motor centres were actually involved in the disease, it seems more than probable that the pressure exerted by the growth must, to a certain extent, have interfered with the functions of those convolutions situated directly in the line of such pressure. Thus may be explained the partial loss of power which existed in the right arm and leg, seeing that the upward pressure of the tumour would more especially affect the posterior part of the left superior frontal convolution, the upper part of the ascending frontal and probably part of the superior or posterior parietal lobule; those regions, that is to say, which Ferrier and others have shown to preside over the movements of the arm and leg. Further, the actual lesions which were demonstrated at the autopsy tend to show that the deafness in the right ear was the result rather of the injury to the brain than of the perforation of the tympanic membrane. Finally, the facts of the patient being a left-handed man, and the injury to the brain being on the left side, are interesting as bearing on the question of aphasia.—Dr. WILTSHIRE asked if any opthalmoscopic examination had been made. He had recently seen a case supposed to be puerperal mania, where, however, a chronic discharge from the ear had ceased the day after confinement, and he concluded that the case was one of meningitis due to extension from the ear. The patient died five days after the cessation of the discharge. No post-mortem was obtained.—Dr. ALTHAUS asked whether the condition of smell and taste had been examined, the centres of which appeared, from Ferrier's researches, to be in the superior sphenoidal convolution.—Dr. DOWSE asked whether the pain was localised to the side affected, or did it extend over the head, down the neck and arm. In several cases he had found pain thus radiating over a wide area, and a more or less paretic condition to exist on the side on which the tumour was growing.—Dr. BROADBENT said the case illustrated the fact of a tumour attaining a considerable size without any ill effects. The symptoms were those of an acute disease and not a chronic one, and probably corresponded with the time at which softening set in. The disease did not involve the centres of taste and smell, but did attack those of hearing; and hence the observation of deafness was of interest. The case would have been even more interesting had the man not been left-handed. He would attribute the paralysis to pressure on the corona radiata containing fibres from the motor centres. Some observers would shift the speech centre from Broca's convolution to the island of Reil; but when the latter is involved, fibres coming from that convolution are cut off. It was remarkable that there was an entire absence of vomiting in the case. If it came to be that tumours so situated were not attended with vomiting, another important localising fact would be established.—Dr. SILVER said that it would be interesting to know in these cases how deep the lesion required to be as regards Broca's convolution. In a case which had been under his charge, and where there was no paralysis, the surface of the left inferior frontal convolution at its posterior part was decidedly softened; the island of Reil to a much greater and more marked extent. There was slowness of speech, together with a certain amount of difficulty, depending on dulness, but there was no aphasia in the strict sense of the term. The suggestion by Dr. Broadbent that the radiating fibres might be intersected by diseased structures would tend to do away with the necessity for localising all such conditions in connexion with the left inferior frontal.—The PRESIDENT asked whether Broca's convolution was at all affected in Dr. Whipham's case, or only the island of Reil.—Dr. WHIPHAM, in reply, said that no ophthalmoscopic examination was made. The pain was chiefly dull, on the frontal and left temporal regions, and in the left eye. No vomiting occurred from first to last. There was no apparent lesion of Broca's convolution, but the island of Reil was entirely softened.

Mr. GODLEE showed the patient whose case had been brought before the Society by Dr. Sturge and himself early in the session, when he had stretched the facial nerve for spasmodic tic. The operation took place thirteen weeks ago, and was followed by facial paralysis until five days ago, when power began to return.—The PRESIDENT remarked that the interest was that so long a period should have elapsed before the return of function, and it would be further interesting to learn if the twitching should also return.

The Society then adjourned.

[Press of matter compels us to postpone the publication of reports of the Medical, the Obstetrical, the Epidemiological, and the Harveian Societies.]

ON Tuesday the Duchess of Edinburgh paid a visit to King's College Hospital. Her Royal Highness was received by General Sir Richard Wilbraham, Chairman of the Committee of Management, and was attended in the wards by Dr. Playfair and Dr. Beale, Professors Wood and Lister, surgeons of the hospital. Her Royal Highness the same afternoon visited the General Lying-in Hospital, York-road, accompanied by Lady Harriot Grimston and Dr. W. S. Playfair. She was received by the Chairman, the Treasurer, the Secretary, and the physicians to the hospital, Drs. John Williams and F. H. Champneys. Her Royal Highness was conducted through the different wards by Mrs. Clarke, the Lady-Superintendent.

Reviews and Notices of Books.

Mittheilungen aus der Ophthalmiatrischen Klinik in Tübingen. Herausgegeben von Dr. ALBRECHT NAGEL. Zweites Heft. 1880. pp. 118. Tübingen: H. Laupp. This part is entirely occupied with a paper by S. Rembold on the important subject of the movements of the pupil, and their significance in diseases of the central nervous system. That the conditions of the pupil are extremely valuable in assisting diagnosis in various states of the system has long been known, yet it is rare in treatises of medicine to meet with precise and express statements in regard to the size of the pupil and the mobility of the iris; and it is still more rare to find the sharpness of vision and the state of the fundus even alluded to, much less accurately given. Rembold's work, which is an enlarged prize thesis of the University of Tübingen, is an endeavour to supply information on this neglected point. He commences his description with an account of the anatomy and physiology of the iris, in which the literature of the subject is given, and devotes the remainder of the work to the consideration of the condition of the pupil in regard to size and mobility in various conditions of cerebral and spinal disease. He finds that pupillary symptoms are not of very great importance in aiding the diagnosis of diffused cerebral disease, so long as the conditions of the pupil are alike on the two sides, and that motionless pupils are of more serious import than contracted ones; but if one pupil is more dilated than the other, and simple hyperæmia or anæmia be excluded, it may be presumed that, in such cases of diffuse disease, exudative processes affecting the meninges on one side more than on the other are present. On the contrary, the conditions of the pupil are of great importance in cases of local disease, and of progressive degenerative processes in the brain—indicating, to some extent, the position of the disease and the prognosis that may be given. Tumours in the cerebellum are frequently associated with mydriasis, but also sometimes with myosis. In regard to spinal diseases myosis may be the expression of diminished activity of the spinal cord, and mydriasis may be a symptom of irritation of the cord, occasioning contraction of the dilatator and of the vessels, owing to stimulation of the sympathetic.

Handbook of Chemical Physiology and Pathology. By VICTOR C. VAUGHAN, M.D. Third Edition. Ann Arbor Publishing Company. 1880. — The rapid succession of editions of this work indicates that the study of physiological and pathological chemistry on the other side of the Atlantic is being pursued with interest. The revival of humoral pathology is one of the great features of the present day. In Germany and in America great progress has been made in this direction, and signs are not wanting that more attention will be paid in England to this branch ot scientific inquiry than has hitherto been the case. Dr. Vaughan's work is a trustworthy guide, plainly and unaffectedly written. It is probable, however, that had the third edition not been called for so soon after the second the author would have had more time to revise certain portions of it and import into its pages some of the more recent observations. To be a little behindhand, however, is no fault in a work purporting to be a text-book. It is undoubtedly better for a student to confine himself to well-ascertained facts than to expend labour in wading through a mass of unverified observations. For the worker engaged in original research, however, a summary of what is being done by others in the same subject is very useful. It would be well, therefore, in forthcoming editions, if Dr. Vaughan gave in an appendix a reference to such work. In this way the student's attention would not be distracted from the consideration of actual facts, whilst those engaged in original research would be able to judge what others were doing in the same direction.

The Journal of Anatomy and Physiology. Conducted by Professors HUMPHRY, TURNER, M'KENDRICK, and CREIGHTON. Vol. XV. Pt. 2. January, 1881. Macmillan and Co.—The chief articles contained in this part are—1. The Bones, Articulations, and Muscles of the Rudimentary Hind Limb of the Greenland Right Whale (Balæna mysticetus), by John Struthers. 2. An Infective form of Tuberculosis in Man identical with Bovine Tuberculosis, by C. Creighton. 3. Case of Medullary Neuroma of the Brain, by Dr. W. Osler. 4. Dissection of the Genito-Urinary Organs in a case of Fissure of the Abdominal Walls, by Alban Doran. 5. Description of a Polygraph, by David Newman. 6. Remarks on the Mechanism of the Secretion of Sweat, by C. Handfield Jones. 7. Anomalous Growth bearing Pilose Skin in the Pharynx of a young Woman, by P. S. Abraham. 8. The Histology of Granular Kidney, by Robert Saundby. 9. Notes on two cases of Cerebellar Disease, by Thomas Oliver. 10. Some Observations on the Colouring Matter of Jelly Fishes, by Professor M'Kendrick. 11. The Nerves of the Hind Limb of the Thylacine and Cuscus, by D. J. Cunningham. 12. Pulse Dicrotism, by W. Fleming; and, lastly, some Anatomical notices.

The Journal of Physiology. Edited by MICHAEL FOSTER. Vol. III. No. 2. January, 1881. Published at the Cambridge Scientific Instrument Company's Works. — This number contains—1. An article, by S. H. Vines, on the Proteid Substances contained in the Seeds of Plants. 2. Sydney Ringer, on the Influence of Season and of Temperature on the Action and on the Antagonism of Drugs. 3. Charles S. Roy, the Elastic Properties of the Arterial Wall. 4. Isaac Ott, on Crossed Hyperæsthesia, and notes on Inhibition.

The Popular Science Review, Jan. 1881. No. 17. Edited by Mr. J. DALLAS, F.L.S. D. Bogue.—This number contains four original articles. The Planet Jupiter in Oct. and Nov. 1880, by W. F. Denning. The Anatomy of the Stag Beetle, by A. Hammond. On Fog, by W. H. Stone, and Some Facts about Fishes, by Mr. Dallas. The paper on Fog, by Mr. Stone, is interesting. He combats Dr. Carpenter's statement that fog is essentially due to carbon particles diffused through the air; for if foggy air be passed through a cotton-wool filter the gain in weight of the filter is very slight; and, again, the microscope shows even a diminution in the number of particles ordinarily present in clear weather. He observes that the weight of carbon in a cubic foot of black smoke is not equal to a single grain, and believes that whilst London fogs are deepened or darkened by the carbon present, they are mainly attributable to climatic conditions. Various suggestions are noticed for the diminution of smoke with the retention of our present open hearths. One of the most feasible, perhaps, is that a form of coke should be introduced into common use, in which the gases should not have been so completely extracted as at present, and which, whilst still yielding a paying amount of gases and ammoniacal compounds, should yet retain sufficient to give a cheerful fire when burnt in an open grate. Another plan, which seems to us reasonable, but which we do not remember to have seen noticed, is that the chimneys containing unconsumed gases might in new houses be made to open beneath the kitchen grate, which would be fed by them, and would thus, by burning the carbon, materially reduce the quantity of it thrown into the atmosphere. It appears that five millions of tons of coals are annually burnt in the metropolis.

The Plumber and Sanitary Houses. By S. S. HELLYER. London: B. T. Batsford.—It is a good sign that works on the technical arts which ensure health in our houses are issuing from the press almost daily, and we may hope before many more years have passed that the journeyman plumber will be armed with so much knowledge of the evils of bad workmanship and ill-devised apparatus that even he will try to help and not to hinder the work which all sanitarians have so much at heart. The volume which is the subject of the present notice is written by a member of an eminent firm of plumbers, and although the view taken of the questions dealt with appears to be that which is only natural in one who is a plumber, a tradesman, and a patentee, the amount of information to be gleaned from it by those who have mastered some of the principles of sanitation is very large indeed. It is somewhat alarming to note the ever-increasing complications of our dwellings. Each constructor pursues his own method, and then exerts his ingenuity to conceal from the purchaser or dweller what his intentions may have been. The book is well got up, is nicely printed and profusely illustrated, and is likely to be of service to builders and health-officers, whether medical or otherwise.

Streets' Indian and Colonial Mercantile Directory for 1880–1. London: G. Street & Co., Cornhill, and Street Brothers, Serle-street.—In these days, when the relations of British medical practitioners with the Colonies and India are more extensive than ever, and health resorts are sought in every quarter of the globe, such a reference-book as this is almost indispensable even to the medical profession. In addition to trade returns, tariffs, and facts regarding populations, Streets' Directory contains particulars of the steam and other communications with the various places named, together with the times and rates of transit, &c. The names of physicians and surgeons resident in the towns and cities of the Colonies and India are given, with information of all kinds likely to be useful to those who are intending to go out, or who have professional or commercial connexions with our colonial possessions. Maps also are furnished of all the principal countries of which particulars are given in the letterpress.

House and Home: a Journal of Social and Sanitary Information for the People.—The number of this useful and unpretending penny journal for the 22nd January gives Professor Fleeming Jenkin's lecture on "Sanitary Houses," delivered before the Society of Arts on the 12th January, in full; a biography of Mr. George Smith, the friend of our canal population and of our outcasts generally; and numerous instructive items on social and sanitary matters.

MEDICAL EDUCATION.

To the Editor of THE LANCET.

SIR,—The sub-committee appointed by the British Medical Association for the purpose of inquiring into the vexed question of medical education have issued their report, which is now in the hands of the individual members of the Association. Personally I think it is a matter of regret that the members of the Committee have given so little attention to that all-important subject—the clinical teaching of medicine and surgery. Doubtless the entire machinery of medical training requires reform, if not complete remodeling; but before this, which must of necessity take time for its accomplishment, can be brought to pass, cannot anything be done for the better training of our medical students?

As matters now stand, all we can hope for is that the student contemplating merely a pass degree should be launched as a practitioner well acquainted with general principles of medicine and surgery. At present our Examining Bodies fail to guarantee that this shall be so; or perhaps I should rather say, there are unfortunately so many loopholes available to the student anxious to avoid our higher diploma granting bodies, that many a degree can be now obtained which, as an index of knowledge, is worthless. Powerless as our professors are to prevent the half-educated student from practising his profession upon his fellow-creatures, still they hold in their hands that monopoly of material which enables the student to present himself before the examining table; and whether the standard of the examiner be high or low, it should be incumbent on the teacher to secure that each individual student should be compelled to submit to a course of clinical instruction in medicine and surgery, which would, at any rate, be some security that in future practice the rudiments of his profession are well known. Of the vast mass of material which our teachers have ready at their disposal for the purposes of clinical teaching, it would be idle now to speak. Could not this wealth of material be better utilised?—utilised so as to prove not only of more benefit to the student, but assuredly in no less direct degree to the public, who have so large a stake in the careful training of our medical men.

Speaking generally, the clinical teaching of our hospitals and schools is defective—defective in principle, from the fact that it obeys no system, and often drifts into mere desultory repetition of the history and symptoms of the patient under notice. Every observant physician must, I think, recognise the patent evils of our medical course. Though at the moment powerless to alter the regulations of our examining bodies, it remains for our professors to see if more cannot be done in improving the efficiency of our students, as regards their knowledge of the natural course of disease, and in relation to its recognition, its treatment, and, above all, its prevention. That our medical students are harassed beyond description by lecture after lecture, the accumulative benefit of which amounts to but little, is continually forced upon our minds; but still that all-important subject of professional education, the study of clinical medicine, remains unhampered. Might not more be done to improve the instruction received under this head? For instance, might not our out-patient rooms be used more freely as fields for teaching in a systematic manner the rudiments of medicine and surgery? No better ground could be found for inculcating lessons as to the very first commencement of disease; but for such teaching to be carried out with good result there must be not only systematic teaching, but systematic attendance on the part of the student; in other words, compulsory attendance on a systematic course of clinical teaching.

Such class instruction once commenced, it would be easy for the physician in charge to produce a syllabus of work to be gone through during term. By an arrangement of coloured tickets a series of cases would follow one after the other into his room, and the student would thus have the advantage of not only comparing the different types of disease, but, perhaps what is of greater importance, of noting, in rapid serial order, the various stages of disease, with their attendant degenerations and complications. By some such organised system as this the physician might be expected to take greater pleasure in his work, which now but too often resolves itself into mere perfunctory accomplishment of duty. His work would become more definite, more exact, and far more productive of good, both to himself and to his class. He would be acquainted beforehand with the work of the day, and would have the advantage of coming primed as to the subject for discussion. Developing the system but little, students would have the means of knowing that on such and such a day cases representing diseases of the heart, lungs, kidney, &c., would be followed in detail, and manifestly, so studied, must prove of far greater value than seen, as they are now, intermingled with cases of but little comparative interest.

Moreover, by a pre-arranged division of subjects each physician would be enabled to select that class of case to which he desired to give special attention, and by knowing the requirements of his colleagues would have the opportunity of passing on those patients whose diseases might offer any special point of interest to them. Carrying the same system into the wards a definite series of cases would be particularly examined at each visit of the full physician, who would have a class awaiting him far better prepared as regards the fundamental principles of medicine than now appears to be the case.

It had been my original intention to have sketched more in detail the scheme which I have but shadowed above—a scheme which, if carried out in its entirety, would give opportunity, for both physician and student, of making far more practical use of that precious mine of clinical material which only the work of a large hospital can give.

I am, Sir, yours obediently,

Green-street, Park-lane. D. W. CHARLES HOOD, M.D.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 19, 1881.

THE physicians of Boston, United States, have inaugurated a measure of internal reform which the medical profession in England would do wisely to imitate forthwith. They have formulated a provision of their ethical code to the effect that "a physician should not append his name, or permit it to be appended, to certificates in laudation of speculative health resorts, health excursions, nutritive or dietetic preparations, proprietary formulæ, wines, mineral waters, beverages of real or supposed medical efficiency, or other hygienic materials." This is a sweeping and practical, but highly necessary, act of self-purgation that the body to which we belong, and in the name of which we claim to speak, sorely needs, and which would sensibly enhance its social and scientific status. The growing practice of attaching the names of members of our cloth to articles sold to the public has reflected no little discredit on the profession in general, and on the individuals who have lent themselves to the more than equivocal practice at which this timely resolution has been aimed. It is not important to inquire whether we in England or our brethren in America or on the Continent are the greatest offenders; let it suffice to recognise that the procedure is an offence. There can be no room to question what the giving or lending of names, colourably to accredit the places, remedies, and appliances with which they are connected, *really* means, and to what it amounts. The name of the person is more in request and estimation than the name of the locality or article to which it is prefixed or appended. When a physician allows himself or others to affix his *imprimatur* to anything which is destined to be advertised, he is plainly permitting *himself* to be advertised. It is useless to mince matters. This is the long and short of the proceeding. Unless, therefore, the medical profession is prepared to place itself on the footing of a fraternity of tradesmen, advertised and recommended by the goods they sell, a stop must, in some way, be put to this form of touting.

We are not disposed to adopt impracticable views of the professional life and its permanent interests. It may be assumed that physicians must live, and live by their calling; but there are two totally distinct and divergent ways of seeking prosperity. The practitioner may strive to make good his reputation by the diligence and excellence of his work, or he may resort to forced and artificial means of acquiring publicity. Practically there is little, if any, difference between allowing a name to be emblazoned on the label of proprietary medicine, or printed at the foot of a testimonial to the excellence of some article of commerce, or inserted in the pages of a guide-book, and displaying it on handbills to be distributed in the street. We will not hesitate to say that when, as happens nearly every week, we are asked to denounce the "unprofessional conduct" of some struggling practitioner who, perhaps, touts for patients by the distribution of printed cards or handbills, we are bound to remember that some of the best known names in the profession are advertised in a fashion not one whit less objectionable. It may seem more respectable to advertise indirectly and under cover of giving a guarantee to the value or purity of some drug or dietetic compound, than to vaunt the skill of an individual directly, but the practical question involved is at the most only one of method. The deed done is the same under all its various forms and disguises. We do not find barristers courting publicity in this way. Why should physicians and surgeons, and the practitioners of medicine generally, be less jealous of the dignity of their calling than those who practise in the law? It is time to look this question of internal reform fairly in the face, to recognise this artifice in its true character, and to reform it altogether.

No man ever made a lasting and honourable reputation in the practice of the healing art who did not first and chiefly owe his fame to the profession of which he was a member. The medical body is not grudging in its acknowledgments of merit; and as a rule its judgment of men and their work is characterised by justice and strict impartiality. Only those who have failed or, in their impatience of the legitimate road to success, have resorted to by-paths and equivocal devices complain of a too tardy recognition. Let the conscience of the practitioner decide this question for itself. Where shall we find any notable number of instances in which genuine ability has had to go a-begging for favour, or true and honest work failed to command respect? There may be instances in which individuals have had to stem the tide of adverse fortune; but if they have not by their own folly or awkwardness missed the flood, they have not failed to reach the desired haven of prosperity. Young men are ever to the fore, and if the elders sometimes seem to lose their footing, that is because they are either remiss or too adventurous, and in their anxiety to keep the lead blunder into deep water. Looking to the reasonable prospects of success with which men enter the medical profession, they will be found, on the whole, to succeed. And the only success worth waiting and striving for is that which attends the man who has so discharged his duty in life as to command the respect and confidence of his fellows. The appeal for recognition lies to the profession itself, and not to the public. The popular voice can only echo the opinion of the profession. The lay community has no means of judging whether a physician is worthy of its confidence except by the results of his enterprise. It is nothing to be widely known or much talked about unless the profession ratifies the opinion which finds expression. The story of the lives of the most successful members of our body would show that the recognition of their interests was first made by their brethren. Speaking generally, we may say that a professional man's repute is well advanced in his own circle before the outside public even hear of him. Those err grievously who think or act as if they thought the profession would accept and honour them, because they had by some stratagem contrived to make their names household words with the community. Such men may be notorious, but not in any worthy sense famous; nor are they commonly—in the long run—successful. It is neither possible to force a reputation in medicine nor to secure the permanent favour of the lay community, except by the countenance and favour of the profession.

There are, moreover, grave and public reasons why the profession should especially set its face against the form of advertising which the physicians of Boston have just stigmatised as unprofessional. A wrong impression is conveyed to the public, and the lay community is misled. The unreflecting are apt to think that if a particular physician has been solicited to give his testimonial to any special article of commerce, he must needs be himself possessed of exceptional powers of judgment in respect to the matters accredited. A moment's consideration will show how easy it would be for a man acting on this suggestion to create a fictitious reputation for his name by gratuitously attaching it to a few judiciously-selected articles. We do not assert that reputations have been made in this fashion, but it is easy to see that they might be so created, and though they would be bubble reputations, unendorsed by the judgment of the profession, it is necessary in the public interests to discourage a practice which may possibly give rise to such untoward results. Every physician of genuine repute and real ability who allows his name to be paraded as the guarantor of a remedy or appliance is personally augmenting the facility with which men of no mark or ability may, by following his lead, come to stand by his side as respectable authorities before an uninformed public. The profession owes it to the community to prevent the possibility of this form of imposture. Again, by lending their names to tradesmen physicians expose themselves to the obvious risk of giving a false character to goods of pretended quality. It is manifestly impossible to ensure that any sample of an article submitted for the judgment of an expert shall be a fair specimen of the commodity in bulk, or that another issue under the same name shall be of equal value. This is a most important consideration, and we venture to think it is one which ought to deter the members of an honourable profession from lending or selling their names for trade purposes. It is, in fact, impossible that any certificate or testimonial can really hold good for any specimen except that to which it immediately relates—that is, the particular sample supplied. The loan of the name for use in the future is therefore an act which can only be characterised as one of moral hardihood and social temerity. It is no part of good citizenship to make the venture.

Look at the matter in what light we may, whether as a piece o personal advertising or indiscreet guaranteeing, it is indefensible and unworthy. We wish there were the smallest ground for hope that the Royal College of Physicians would be stirred to emulate the vigorous self-purgation so gracefully achieved by the physicians of Boston. Unhappily there is not the remotest probability of the dignified but lethargic corporation in Pall-mall being aroused to healthy activity by example or remonstrance of any kind. Nor is the Royal College of Surgeons without responsibility in this matter. It includes, among its members, men whose names figure conspicuously in the public prints. The profession must act for itself if it is to be cleared of a standing reproach, and its honour is to be vindicated. Personal action may do much, but there must be concerted action if all that the occasion demands is to be accomplished. It would be well if something like a *pronunciamiento* of the medical profession in relation to this question could be elicited. What the physicians of Boston have done, the physicians of the United Kingdom can do. Let those who have sinned in this matter sin no more, and let those who have not as yet flagrantly offended resolve to avoid offence. It will be well for the profession, and for the interests of commerce too, when the practice of giving and vaunting medical testimonials, and parading the names of physicians and practitioners in the manner denounced by our brethren across the Atlantic, is finally abandoned.

◆

AT the time of our writing we have good reason to believe that the Government has not decided on the appointment of a Royal Commission for the purpose of settling the questions connected with the amendment of the Medical Act of 1858, to which two or three Governments have been committed, as well as the Medical Council and the whole of the medical profession. A leading contemporary was at least premature in speaking confidently as to such a step. It is no doubt true that the Government have some thought of such a course, and it is possible that the opponents of reform may think in this way to prolong their untenable position, and perhaps to postpone indefinitely those changes which, in the estimation of all outside, are needed in the Medical Council and the medical examining system of the country. But we repeat that our contemporary was in haste in the matter.

We hope the Government will deliberate well before taking a course which seems to unsettle everything and to cast discredit on so much good evidence. Is it possible for the case of the Medical Council and the existing corporations to be set forth by better witnesses than Dr. ACLAND, Mr. SIMON, and Sir JAMES PAGET? Can the inefficiency of the Medical Council, the inequality of the examining boards, and the defects of the best of the corporation examinations be made more clear than by the admissions of these witnesses, and by the unrefuted statements of the few who have yet been examined on the side of reform? Is all this evidence to be disregarded and wasted, when the examination of a few more witnesses would complete the case? We certainly fail to see the necessity. There may be an indisposition on the part of the members of the present Parliament, excited and distracted by other questions, to complete an investigation very well begun, and the break in the continuity of the inquiry by the dissolution of Parliament may justify the creation of an entirely fresh one. But these are points really very doubtful, and worthy of the consideration of the Government, which we believe will be accorded to it.

At the same time, if a Royal Commission is to be nominated, we shall heartily bow to that mode of investigating a question which we must admit to be technical and seemingly difficult, though—apart from pecuniary and corporation considerations—exceedingly simple. A Royal Commission has certain advantages over a Select Committee. It is not necessarily confined to members of Parliament. Any suitable person can be nominated a Royal Commissioner. Its investigations are not suspended when Parliament is sitting, as in the case of a Select Committee. It can continue its work in the interval of the sessions. These are the chief differences between the two modes of inquiry, and perhaps they show a balance of advantage on the side of the Royal Commission, if it be well and impartially chosen. It is of course very easy to elect a Royal Commission that will see nothing but beauty and perfection in the actual and traditional, as any other form of inquiring body. But we have some confidence that the Government, if it accepts the responsibiltty of disregarding all that has been said and done in this cause for ten years past, will elect a Commission so fair and so strong in its intelligence and impartiality as to hold out a prospect of the termination of a "schism in the medical profession," as Mr. SIMON has called it, and of a controversy of which we, at least, are heartily tired. We repeat our conviction that a Royal Commission is unnecessary; that the facts are admitted or indisputable; that a Select Committee should be able by the middle of May to present an admirable report laying a secure foundation for sound legislation. But believing in the anxiety of the Government to do what is right in regard to old and in some instances perfectly effete corporations, and to a most costly and inefficient Medical Council, we shall bow to its decision.

◆

THE elasticity of the arteries, though it is well known to exert a powerful influence on the circulation of the blood, has hardly been studied with the attention it deserves. ED. WEBER was the first to institute the ingenious comparison between the elasticity of the arteries and that of the air in the air-chamber of a fire-engine, and to show clearly that its principal action is to convert the intermittent flow caused by the rhythmical contractions of the heart into a comparatively uniform and continuous current; but few have occupied themselves with determining with precision the degree of elasticity in particular vessels, the extent to which they yield on pressure, and their resistance to rupture. MOENS, indeed, found that the elasticity was equal in the longitudinal and transverse directions, and that its coefficient increased with the weighting. VOLKMANN observed that the carotid of a sheep sustained without rupturing a pressure of 2·25 meters of mercury, which is about fourteen times greater than that of the ordinary blood-pressure. All experimenters agree that the elasticity of the arteries is very perfect, though small; that is, that whilst they are easily extended or compressed according to the mode in which the force is applied, they recover their original form very perfectly.

Dr. ROY has just made an important communication to the subject in the pages of the last number of MICHAEL FOSTER'S *Archives of Physiology*. He states that he entered upon the consideration of the elasticity of the arteries with the view only of determining by direct experiment the relation that exists between the intra-arterial pressure and the cubic capacity of any given portion of artery; but as he continued to work at the subject new points arose, the examination and discussion of which have led to the publication of the present memoir. In the first place, he finds, with WERTHEIM, that whilst inorganic substances, such as metal wires or glass rods, extend in proportion to the weighting—at all events within certain limits,—in the case of moist animal tissues the increments in length produced by the addition of successively increasing weights diminish gradually in proportion to the weights employed. Dr. ROY next proceeded to investigate whether the thermo-elastic properties of animal tissues were identical with those of inorganic substances. Now, with one or two exceptions, all bodies on being compressed become warmer, and on being stretched cooler. But the animal tissues agree with the exceptions to the rule—to wit, bismuth and caoutchouc—in becoming warm when stretched, whilst their temperature falls on being relaxed.

On examining by experiment the relation between the internal pressure and the cubic capacity of the arteries, Dr. ROY found that the aortic walls are most elastic at pressures corresponding more or less exactly to the normal blood-pressure, and no difference can be detected in the degree of elasticity between the time of death of the animal and the period when putrefaction has commenced. The elastic properties of the arteries taken from different animals, even of the same species, may vary considerably, and still greater differences result from malnutrition, such as that produced by febrile processes. But in a functional point of view it may be said that the elastic properties of the aorta and large arteries of any given animal are identical, so that the ratio of increase of volume to increase of pressure is the same in the aorta and its branches. Dr. ROY in subsequent sections discusses the effects of disease and of age on the elasticity of the arteries, and demonstrates by diagrams the considerable modifications that are produced by diseases affecting the general nutrition, and the fact that the elasticity is perfect only in childhood. The whole paper is a valuable contribution to our knowledge of this subject.

◆

THE aims of the forthcoming International Medical Congress are very properly purely scientific, and we trust that much advancement in the science of medicine may be effected by the discussions on various topics which are to be conducted in London in August next by so many illustrious medical professors. The Congress has not been forgetful of the adage that the mind is reached more quickly through the eye than through the ear, and accordingly a museum of objects of scientific interest will form, as it were, one of the sections of the Congress, a section which will have intimate and necessary relations with all the others. The Museum Committee of the Congress felt very strongly that its work lay mainly in collecting pathological specimens illustrative of discussions which were to take place in the other sections; but, on the other hand, it felt that in the wide domain of medicine there were many other objects — new inventions, new instruments, new drugs, and the like—which ought to be exhibited to the members of the Congress. The extension of the museum beyond the domain of pure science was, however, a difficult matter. Besides the difficulty of selection and the invidious duty of rejection there was the still greater difficulty of finding space sufficient for anything like a complete exhibition of what one may call the medical industries. When, therefore, the hon. secretary of the Parkes Museum made the suggestion that possibly the Committee which he represented might be willing to organise an exhibition illustrative of every branch of the medical and sanitary sciences, that suggestion was welcomed by the Museum Committee of the Congress and met with unanimous support from the Executive Committee of the Congress, to which the matter was referred. When the Executive Committee of the Parkes Museum, backed by the Executive Committee of the Congress, made application for space to hold the proposed Exhibition in the Exhibition Buildings, at South Kensington, the Royal Commissioners for 1851, feeling no doubt that the proposition was one which met with the cordial approval of the heads of the medical profession in this country, gave their ready assent, and promised to place at the disposal of the Parkes Museum Committee all their available space in the buildings at Kensington-gore. Thus it has come about that an International Medical and Sanitary Exhibition on a scale probably never before attempted is to be held in London in July and August next.

The Parkes Museum Committee have, wisely, we believe, instituted a Special Committee for the purposes of the Exhibition, and this Committee—with the President of the College of Surgeons as its chairman, and numbering among its members the President of the Pharmaceutical Society, six physicians and surgeons from five different medical schools and hospitals, together with other members eminent as architects and sanitarians,—is, we think, likely to command the confidence of the profession and those who are interested in the various industries connected with medicine and hygiene.

The Exhibition will open a fortnight before the sittings of the Congress commence—namely, on the 16th of July—and will close on August 13th, five days before the termination of the Congress. The exhibits, which will comprise everything that is of service for the prevention, detection, cure, and alleviation of disease, will be arranged in two chief sections, Medical and Sanitary, and a third Miscellaneous section, in which, we doubt not, anything that is of interest to the medical profession will be able to find a place.

The Medical Section will include surgical instruments and apparatus; appliances for the ward and sick room; drugs, disinfectants, dietetic articles, and mineral waters; electrical and optical instruments, and other apparatus employed in the investigation of disease; appliances used for the treatment of the sick and wounded during war, street ambulances, &c.; appliances used in teaching medicine, books, diagrams, models, &c. The Sanitary Section will include domestic and hospital architecture; ventilation, lighting, warming, and decoration; sewerage, drainage, waterclosets, sinks, baths, &c.; water-supply and filtration; health resorts, sanitaria, &c.

The Exhibition is to be international, and we understand that every effort is being made to make it known on the Continent of Europe and in America. The secretaries of the Congress have, at the suggestion of the secretary-general, undertaken to circulate the prospectuses of the Exhibition, printed in English, French, and German, with the various documents which they are scattering broadcast over the world, and this in addition to other means will certainly secure a good representation of foreign exhibitors. We trust this will be so, and we hope that such a chance of learning whatever our foreign brethren have to teach will be appreciated by manufacturers in this country. On the other hand, we hope it will be remembered that this country has a reputation to maintain. English manufacturers have been in great repute throughout the world for a century past. In the art of practical sanitation we have for a long time stood alone; English cutlery has ever been regarded as the best that can be obtained. England, with its thousands of ships and colonies extending to every corner of the earth, is the great market for the various organic and mineral products which form the staples of pharmacy. Thus our foreign guests may fairly expect to find that the English exhibitors have provided an instructive show worthy of a nation which is nothing if not practical; and we trust that English manufacturers will be put upon their mettle, and will remember that it is their duty to see that our reputation is maintained in the eyes of our foreign guests.

Annotations.

"Ne quid nimis."

HÆMORRHAGIC SMALL-POX AMONG ESQUIMAUX IN PARIS.

IT is not often that an opportunity is afforded of witnessing in Europe the effect of acute specific diseases on individuals of races which have been little exposed to their action. Such an opportunity was, however, presented lately by a sad epidemic of small-pox among some Esquimaux who had come for exhibition at the Jardin d'Acclimatation, where they arrived from Crefeld on January 2nd, having previously been at Darmstadt, Frankfort, Prague, and Berlin. One of the troupe, a girl aged sixteen, had died at Darmstadt, twelve days after leaving Prague, without presenting any eruption. At Crefeld a woman of forty died, also without any eruption, and a young child, who died on the second day after the appearance of a distinct eruption of small-pox. Four or five days after their arrival in Paris the rest were vaccinated, on the 5th and 7th of January. All were ill, and as a young child presented an eruption, they were all sent to the small-pox ward of the Hôpital St. Louis, under the care of Dr. Landrieux, who has related the cases in *L'Union Médicale.* The variola began in all before or immediately after vaccination, and hence this had no effect. They all (eight in number) died, three in the period of invasion, without skin eruption, but with intense headache and pain in the back. Four others died during the period of eruption, and all presented almost continuous hæmorrhage from the bronchial tubes, and passed urine which appeared to be pure blood. The eruption came out slowly, the pustules being distended with blood, and some had the appearance of bullæ of pemphigus. The temperature varied between 103° and 105°. In one of these cases also there was no rash; death occurred without delirium by septicæmia or asphyxia. The unfortunate men had led temperate lives, and had not been addicted to alcohol. In four cases post-mortem examinations were made. The internal organs presented abundant hæmorrhages. The blood presented a large excess of leucocytes, and the red corpuscles were, as is usual in such cases, crenated, and did not form rouleaux. The liver in each case was enormously enlarged, pale, and friable, and offered all the characters, naked-eye and microscopic, of intense fatty degeneration. The mesenteric glands were much enlarged, without any corresponding alteration in the mucous membrane of the intestine. The spleen was natural in size, but the kidneys were greatly enlarged by congestion and fatty degeneration. The heart also presented fatty degeneration. The condition of the liver, to which, perhaps, too much weight is given by Dr. Landrieux as the cause of the rapid mortality, is ascribed to the habitual food of the people. The occurrence, however, teaches very strongly the lesson of the importance of the vaccination of such natives of uncivilised countries, brought to Europe for show, immediately on their arrival. The public authorities ought invariably to take means to ensure effective vaccination.

OCCLUSION OF THE CORONARY ARTERIES.

AN instructive case has been recorded by Dr. Karl Dehio of Oldenburg. A man, thirty-one years of age, had suffered from attacks of sudden cardiac distress, accompanied by a sensation of painful pressure in the region of the heart, and a feeling of great anxiety. These attacks ultimately recurred daily. At last a very severe seizure occurred, characterised by pallor of the skin, feeble impulse of the heart, indistinctness of the sounds, and apparently failure of the left ventricle, while the right ventricle continued to contract forcibly. There was also acute œdema of the lungs, the progress of which could be watched during the attack, in which he died. It was found that "sclerosis" of the wall of the aorta had led to occlusion of the entrance to the left coronary artery, and had narrowed that of the right. There was fatty degeneration of the walls of the heart. The previous attacks were ascribed to the gradual narrowing of the vessels, which rendered the blood-supply to the heart insufficient to enable it to respond to the call for any extraordinary exertion.

It is of interest, in connexion with this case, to note some experiments on the effect of sudden occlusion of the coronary arteries which have been communicated by MM. G. Sée, Bochefontaine, and Roussy to the Académie des Sciences. The first to observe the effects of artificial closure of the coronary arteries was Chirac. In 1842 his experiments were repeated by Mr. Erichsen, who found that, in the dog, ligature of these arteries causes progressive retardation of the pulsations of the heart, followed by its arrest in from three to twenty-one minutes. He found that the contractions cease in the following order when the left artery is ligatured: first in the left ventricle; then in the right auricle; then in the left auricle; and, lastly, in the right ventricle. Schiff has maintained that the ligature of one coronary artery causes *immediate* paralysis of the cardiac region which it supplies, while the neighbouring parts preserve their usual rhythm. The experiments of the French investigators were made upon dogs under the influence of curara, morphia, and chloral, of the two latter combined, or of daturine and curara, artificial respiration being kept up. The coronary arteries were suddenly tied at their origin, while the heart was still beating vigorously. At the end of a period of one or two minutes, the rhythmic ventricular contractions, a little retarded, ceased suddenly, and were replaced by a disordered, tremulous movement, more or less violent, of the muscular fasciculi of the ventricles, analogous to that which has been observed to succeed the faradisation of the heart. It was most intense in the right ventricle. Soon the two ventricles became swollen, the auricles continued to supply them with blood, and the arterial pulse disappeared. In order to produce this effect it is not necessary to tie both the arteries at their origin. In one animal the posterior coronary artery was tied, and then two principal trunks of the anterior artery—the auricular and ventricular trunks—leaving free the branch which passes in the interventricular septum. The ventricular contractions became weakened in the same time, and then suddenly ceased, being replaced by disordered contractions, while the auricles, after a moment's pause, resumed their rhythmical pulsations, which gradually became weaker, and ceased. In another experiment the ventricular branches of the right and left coronary arteries alone were tied. The same results followed, and were also produced when the whole of the anterior coronary artery, or its two principal trunks, were closed. In one experiment similar phenomena were produced in six minutes by the closure of the posterior coronary artery alone. In another, the ligature of this vessel for five minutes produced no effect whatever. The anterior artery was then tied, and the disordered action of the heart immediately commenced. The division of the vago-sympathetic trunks in the neck did not modify these phenomena, and they were unaffected by strong faradisation of the peripheral extremity of the superior cervical ganglion.

The conclusion drawn from these facts is that the arrest of the circulation in the heart, by obliteration of the coronary arteries, modifies the contractility of the muscular fibres of the heart, so that they become incapable of contracting in their normal rhythmical manner. It may be objected that the condition of the ventricles is due to the excitation of the peri-vascular filaments, which, irritating the intra-cardiac ganglia, derange the normal action of the fibres. In order to ascertain the force of this objection, water charged with lycopodium spores was injected into the aorta by a branch of the anterior coronary artery. The systolic flow carried the lycopodium spores to all parts of the heart. In a minute and a half or two minutes the ventricles became pale, and immediately the tremulous movement, characteristic of the occlusion of the coronary arteries, set in, and presented the same characters as when produced by their ligature. The phenomena observed were thus simply the effect of the arrest of the blood-supply.

THE SHEFFIELD POISONING CASE.

THE facts of this remarkable case are briefly as follows:—Mr. Booth, his wife, an invalid son, and a daughter, resided at Gell-street, Sheffield, their servants being Parker, a housemaid, and Horton, a cook. In addition there resided with Mr. Booth's family an elderly lady named Roberts. On Sept. 1st, 1880, Annie Wilmot, a nurse, was engaged to look after the invalid son. This son died suddenly in convulsions on Oct. 8th. Notwithstanding the death of her patient, Wilmot, who had ingratiated herself with the family, was asked to remain. On Oct. 16th, Miss Booth died suddenly in convulsions. On Oct. 16th also, Mrs. Booth, who was much depressed by her double bereavement, began to suffer from cramp and twitching of the left leg. On the 17th the twitching had extended to the face and fingers. On the 18th these symptoms (which suggested the possibility of strychnia poisoning to Mr. Pye-Smith and Mr. Thorpe, the two medical men who were called in) continued. On the evening of the 18th Mrs. Booth was better. On Oct. 21st, Mrs. Booth's symptoms were those of opium-poisoning, and she remained unconscious for some time; she vomited, and the vomited matter on analysis by Mr. Bell and Dr. Tidy was found to contain morphia. Mrs. Booth ultimately recovered. Wilmot was charged at the Leeds Assizes, before Mr. Justice Manisty, with attempting to murder Mrs. Booth by administering poison to her, and at the trial the following facts were elicited:—1. That Wilmot had been seen at 10.15 on Sunday, Oct. 17th, to come out of the surgery with a bottle of white fluid in her hand, which she was measuring carefully into a medicine-glass. This was done openly; the bottle was left upon the kitchen-table, and what the bottle contained was never proved. 2. On Oct. 19th Wilmot sent the housemaid to the chemist's to get a bottle (belonging to a small portable medicine-case) filled with tincture of opium. The bottle and case have since disappeared. 3. On Oct. 21st Wilmot sent the housemaid to the chemist's for some morphia. 4. Before the magistrates she had denied sending the housemaid either for opium or morphia. 5. She told the housemaid on the 17th that Mrs. Booth desired her to go for the tincture of opium, which was contrary to the fact. 6. On the 19th Wilmot gave Mrs. Booth some hock, which was "nasty and repulsive," and caused Mrs. Booth to refuse to take any more, and to ask Wilmot "what she had put in it?" 7. On the 20th Wilmot gave Mrs. Booth some whisky-and-water, which looked muddy, and which tasted nasty.

There was no formal defence, but in the cross-examination of the witnesses for the prosecution it was proved:—1. That Wilmot had made no secret of her sending for narcotics, &c.

2. That other persons besides Wilmot had administered food and medicine to the deceased. 3. That the sending of the maid Parker to the chemist's was not an extraordinary occurrence in Mr. Booth's establishment. 4. That no poison was ever detected in the dregs of any article of food or drink given to Mrs. Booth. 5. That no adequate motive had been discovered for the crime. 6. That Wilmot had always been kind to Mrs. Booth, and seemed really distressed at her dangerous condition. 7. That the prisoner had always borne a good character. 8. That the cook who had prepared the food had since gone to Australia. The verdict was to the effect, "That Wilmot had administered morphia to Mrs. Booth, but with what intent there was no evidence to show."

THE PERIOD OF LATENT SENSATION.

A SERIES of investigations by Vintschgau and Hönigschmied on the interval between the application of a sapid substance to the tongue and the resulting sensation of taste led to the conclusion that the power of discrimination in different parts of the body had a considerable influence on the interval which elapses before a sensation is perceived. Vintschgau has examined the facts bearing on this relation afresh, and has compared his results with those obtained by previous investigators—Helmholtz, Hall, v. Kriess, &c. His investigations were chiefly made upon the tongue, which he finds particularly adapted for the experiments. The tongue was touched with a point, while the person examined broke an electrical current with his left hand as soon as he perceived the sensation. The average of the whole series of observations on the first individual tested was for the middle of the tongue ·1908 sec., for the tip of the tongue ·1607 sec., the difference between the two parts being ·0301 sec. On exclusion of some doubtful observations, the average was for the middle of the tongue ·1877 sec., for the tip ·1522 sec., giving a difference of ·0355 sec. Observations on a second individual showed that the period is longer for the root of the tongue than for the middle or tip. Similar results were obtained on a third and fourth person. Observations made by Vintschgau on himself gave no difference between the middle and the tip.

Further observations were made on the palmar skin of the first and third phalanges of the middle finger, on the dorsal side of the first phalanx, and over the head of the metacarpal bone of the middle finger, in three persons. In the first individual tested it was found that the interval, excluding some doubtful observations, was on the palmar aspect of the third phalanx ·1629 sec., on that of the first phalanx ·1597 sec., on the dorsal surface of the first phalanx ·1822 sec., and on the knuckle ·1977 sec. The touch on the dorsal side was thus always noted later than that on the palmar aspect, which corresponds with the degree of tactile discrimination. In a second individual there was no notable difference between the interval for the dorsal and palmar aspects. But in both persons the interval for the palmar aspect of the first phalanx was shorter than that for the palmar aspect of the third phalanx, a fact for which no explanation is given. On himself Vintschgau only examined the intervals on the palmar aspect of the third phalanx and the knuckle, and found the period longer for the former than for the latter. It is possible that the cause of these differences may be in the sensorium, but it seems more probable that it is to be found in the different development of the power of localisation. At any rate, the observations corroborate the fact that the latent period of sensation varies in different parts, and that it varies in the same parts in different individuals in a manner not altogether easy to explain.

Another fact demonstrated by Vintschgau is that an electrical stimulation is sooner perceived on the tip of the tongue than on the tip of the finger. This might be expected from the longer course of nerve which the sensation has to travel; but it may be in part also due to the greater power of tactile discrimination possessed by the tip of the tongue, in accordance with the facts ascertained regarding touch.

THE PEABODY FUND AND CLASS MORTALITY.

THE trustees of the Peabody Donation Fund have just issued their Sixteenth Annual Report, which, although as usual exceedingly terse, is full of interest from a social, sanitary, and financial point of view. It is, at any rate, useful to be reminded once a year of the almost silent but steadily progressive influence for good of this noble gift to the poor of London. Glancing at the capital account, we find that Mr. Peabody's successive gifts, which amounted to half a million sterling, have, with the addition of accruing rent and interest, already increased by 50 per cent., and become three-quarters of a million, which is all employed in furthering that incalculable boon to the poor of London—the improvement of their dwellings. At the close of last year the trustees had housed 9899 persons in their improved dwellings, and had purchased no less than six other plots of ground from the Metropolitan Board of Works, on some of which the new buildings are approaching completion. Before the close of the present year the trustees hope to complete additional accommodation for 760 families, or upwards of 3500 individuals, which will raise the aggregate population of the Peabody Buildings to 13,500 persons. It is often asserted that these improved dwellings are not used by the class for which they were intended, but it is interesting to learn from the report before us that the average weekly earnings of the heads of families in residence at the end of last year were rather less than 23*s.* 6*d.*, and that the average rent of each tenement was 4*s.* 4*d.* It is evident that the population of the Peabody buildings is distinctly a working and weekly waged class population. From this point of view the statement that the death-rate during last year in the Peabody buildings was equal to 19·7 per 1000 of their population has especial interest. But for the fact that the population belongs exclusively to the poorer of the working classes, a little surprise might be felt that the death-rate in these improved dwellings was only 2·5 per 1000 below the average rate in the whole of London, as this apparent deficiency in the death-rate would disappear if the due proportion of deaths in public institutions (workhouses, hospitals, and lunatic asylums) were added. As a death-rate, however, among a class of population in which the average earnings of the heads of families is but 23*s.* 6*d.*, this result is one which raises great expectations of the future effect of the Peabody Fund, together with the effect of Associations for improving the dwellings of the poor upon the sanitary condition of London.

GLASGOW LOCK HOSPITAL.

IN the seventy-fifth annual report of this institution it is stated that of 414 patients treated during 1880, 390 were dismissed cured. The average cost of each patient dismissed was 34*s.* 6*d.* Some of the other statistical facts presented in this report are of considerable interest. Thus it is shown that the great majority of the patients were young persons. Some of them were mere children. In such cases the police authorities were, whenever possible, communicated with. The average age of those dismissed cured did not exceed twenty-one years and a half; of these patients 235 were inmates for the first time, 93 for the second, 43 for the third, 13 for the fourth, 3 for the fifth, 2 for the sixth, and 1 for the seventh. More than 10 per cent. of the patients during the year were restored to their parents and relatives, or, at their own desire, sent to a reformatory institution. The medical officer's report also stated that the disease for the cure of which the hospital was opened had become milder in its type, altogether less fatal and more amenable to treatment than formerly, while at the same time its prevalence had become greatly diminished, and its sad effects, formerly to be seen upon the young and innocent, even among the better class of the people, were not now so often encountered.

THE TREATMENT OF MALIGNANT PUSTULE.

M. Verneuil, in an important communication to the Académie de Médecine on this subject, reminded his hearers that the malignant pustule consists of three zones or regions: first, the slough or gangrenous zone with its characteristic vesicles; secondly, an indurated zone presenting on its surface other vesicles; and, lastly, the zone of œdema. Until recently surgeons have concentrated their attention on the central or gangrenous zone, have applied almost no treatment to the indurated zone, and always none to the zone of œdema beyond poulticing and leeching. According to M. Verneuil it is important to apply to each zone special and energetic treatment. These are—first, to destroy or excise the gangrenous part; secondly, to incise and cauterise deeply the zone of induration; thirdly, to disinfect, by antiseptic hypodermic injections, the zone of œdema; lastly, to employ general antiseptic treatment, such as the internal administration of iodine or some other efficient internal antiseptic. The experiments of Davaine have shown that iodine, even in small doses, has an efficient neutralising action on the virus of anthrax, and it is possible, according to M. Verneuil, to introduce into the circulation a sufficient quantity of iodine to produce this effect. The hypodermic injections into the œdematous zone should also consist of iodine, ten drops of a one-half per cent. solution. The first case thus treated was one of malignant pustule on the arm, in which the actual cautery had failed, and amputation was contemplated; the treatment was perfectly successful. In another case the pustule was situated on the eyelid, inoculation having been effected by inadvertently scratching a pimple there. The eyelid was much swollen, and presented the characteristic vesicles and bullæ, and there was considerable œdema of the whole of that half of the head. The temperature was 103°; the patient was delirious, sleepy, and vomited continually. The pustule was destroyed by means of the thermo-cautery. In the zone of induration a series of punctiform cauterisations were made with the same instrument, to a depth of one-third of an inch, and then the solution of iodine was injected in the œdematous part at intervals of five centimetres. The temperature rapidly fell. The delirium, somnolence, and vomiting ceased as if by magic, and on the third day the patient was out of danger. In the discussion which followed M. Léon Labbé agreed with M. Verneuil as to the necessity of cauterisation in the zone of induration, and employed it even in the œdematous region. He was inclined to attribute more importance to this measure, employed in an energetic and even, as it might seem, barbarous degree, than to the injections of iodine. M. Gosselin urged the importance, before applying the treatment to every pustule which had a malignant aspect, of ascertaining if it were really anthrax, by microscopical examination of the serum in the vesicles and of the blood. M. Verneuil, speaking from the standpoint of practical surgery, maintained that better indications could be drawn from the clinical aspect of the affection than from the presence or absence of bacteria. He had seen cases in which bacteria were found in the vesicles and in the blood, although the symptoms were benign, and others in which, in spite of the absence of bacteria, the augmenting gravity of the affection necessitated the use of the most energetic remedies.

THE ARMY ESTIMATES.

The estimated expenditure on account of the medical establishment and services for the year from April 1st, 1881, to March 31st, 1882, amounts to £300,480, being £7960 under the estimate for the current year. The reduction is due to several causes: chiefly, the retirement of a large number of officers in receipt of the maximum rate of pay, a decrease in the number of civil practitioners employed in consequence of the Army Medical Department having nearly reached its normal establishment, a decrease in the number of surgeons on probation at Netley, for the same reason, and to the Irish militia not being called out this year for training. In addition to the above sum, however, there is a charge of £5750 for the staff employed at the Army Medical Board, and one of £6434 for the medical school at Netley, while £1875 should be deducted as the charge for the unnecessary military staff at Netley, which we regret to see still borne on the estimates. The aggregate expense, therefore, of the Army Medical Service may be stated in round numbers at £310,800. As regards the *personnel*, the numbers of the medical officers employed are the same as last year, with the exception of an addition of three Acting Medical Officers employed at Brigade Depôts, and a reduction of one Deputy Surgeon-General at the Medical Board, where the sanitary and statistical branches have been combined under one head—a paltry saving of very doubtful expediency. In the estimates provision is made for 30 surgeons on probation at Netley, instead of 100 as last year—a very satisfactory proof that the present Warrant has enabled the authorities to bring up the number of medical officers to the authorised establishment.

The sum required for the pay of army medical officers on the Home Establishment is £176,018, with servants and mess allowances of £7180; and in the colonies, £51,705, with £2880. Under the head of "pay of civilian medical practitioners and medical bills," £11,000 are required for home, and £125 for the colonies, the former being a reduction of nearly £6000 and the latter of £750 compared with last year. For the pay of nurses in female hospitals, miscellaneous labour, &c., £2720 are taken, and for departmental and extra duty pay of Army Hospital Corps £20,646. The amount for these two items was not stated separately in last year's estimates, but there is an increase on the aggregate of £1277.

We have on several occasions called attention to the injury done to such an establishment as the great invaliding hospital of the army by attaching to it a discharge depôt for time-expired men. We sincerely trust that Mr. Childers will repeat his visit to Netley, and take the opportunity of making inquiries into the injurious influences of this arrangement. We feel confident that the result of such a course would be an immediate change of system, reserving Netley exclusively for invalids and sick, and forwarding all time-expired men to their Brigade Depôts, to be discharged to their homes or place of enlistment when the necessary formalities of completing their documents and settling all claims for pay or pension have been completed.

HOSPITAL SUNDAY IN MANCHESTER.

The *Manchester Guardian* publishes a very sensible letter from the Rector of Christchurch, Salford, on the system of giving "recommends" to the clergy in return for collections. Until the whole system of giving letters is abolished in favour of admission on a strict system of merit and urgency, it is unreasonable not to give clergymen a *quid pro quo*. They are naturally brought into contact, sometimes very painfully, with sickness. Their interest in Hospital Sunday is greatly increased by acquiring some means of helping the poor to admission into hospitals. If the rules permit the churches or the committee to require too much, the proper remedy is to alter the rules, but by no means to allow any defect of this kind to interfere with a hearty support of the approaching collection.

EPIDEMIOLOGICAL SOCIETY.

AT the meeting of the Epidemiological Society, held at University College on February 2nd, the President, Sir Joseph Fayrer, in the chair, it was resolved to utilise the constitution of the Society for the purpose of investigating the following points, and special committees were appointed for this object:—1. The evidence which the present state of medical knowledge supplies as to the conditions affecting the protection against Small-pox afforded by Vaccination. The committee to consist of Dr. Robert Cory, Dr. John McCombie, and Mr. Shirley Murphy. 2. The circumstances under which Enteric Fever originates, and the means by which it is disseminated. Committee, Dr. Alexander Collie, Dr. G. C. Henderson, and Dr. E. J. Russell. 3. The circumstances under which Diphtheria originates, and the means by which it is disseminated. Committee, Dr. J. B. Longstaff, Mr. A. H. Smee, and Dr. William Squire.

THE death of Mr. F. J. Short, of St. Bartholomew's, under very sad circumstances, has caused an unusual amount of sorrow and sympathy, as especially evidenced on the day of his burial. Several of his fellow students attended, and letters from others were received, expressing in very strong terms their grief at their loss, and appreciation of his character. One says, "He was my ideal of a perfect Christian gentleman, and if ever man was ready to meet his end he was." He seems to have been universally respected, and many living on the "upper Thames" will remember the tall, quiet, gentlemanly man, who for months together was sketching there. He entered the medical profession a few years ago, had gone to assist his friend Mr. Taylor, of Bocking, on the 2nd inst., and died of malignant small-pox on the 10th, contracted while acting as a temporary assistant in London.

THE College of Physicians in Ireland, as trustees of Sir Patrick Dun's Hospital, have achieved a success in the matter of recovery of rent which has served to put a different complexion on the political affairs of Waterford. The lawful seizure of a tenant's cattle for arrears, and the effective sale of the stock through the agency of the Property Defence Association, and under the protection of a large force of constabulary, seem to have so cowed the adherents and dupes of the Land Leaguers that a large number of tenants on the estate paid up outstanding accounts at once, and the remainder have promised to pay, alleging fear, not destitution, as the cause of delay.

OUR correspondent from India writes: "What a sad business there was at Guy's about the nursing! We went through exactly the same sort of thing out here in Madras. At first the nurses *and priests* had it all their own way; but ultimately, thanks to the shrewd common sense of the Duke of Buckingham and his daughter, Lady Mary Grenville, they were found out, and had to pack up and go."

DR. JOHN WATT REID, Director-General of the Navy Medical Department, has been appointed Honorary Physician to the Queen, in the vacancy created by the decease of Dr. Davidson.

AN effort is being made, it appears, to consolidate the Medical Colleges of Cincinnati into one, to form the medical part of the State University. A similar attempt, made some time back, proved abortive.

THE Medical Council did wisely in appointing, in the place of the much lamented Dr. Andrew Wood, a London Chairman of the Business Committee; and of the London members of the Council, none could have been found more fit by habit and varied experience for the duties of the post than Dr. Pitman.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL INSPECTORS OF THE LOCAL GOVERNMENT BOARD.

Cemeteries.—Under the Public Health (Interments) Act, 1879, sanitary authorities are empowered to establish and maintain cemeteries, and, with the sanction of the Local Government Board, to borrow money for defraying the cost. Under these circumstances, the Board has thought it desirable to issue a memorandum on the sanitary requirements of cemeteries, setting forth those points which presumably will influence the Board in its judgment on the suitability of the site of a proposed cemetery. This memorandum has been prepared by Dr. H. Franklin Parsons, and embodies the principles laid down by various English and foreign authorities as requisite to be observed in the establishment of a cemetery to prevent it from becoming a source of nuisance and danger to the living. The memorandum presents an admirably clear view of cemeteries in their sanitary relations. Dr. Parsons deals successively with the questions of soil, situation, particularly in relation to water-supply and sufficiency of space. He does not confine himself to a mere recapitulation of already accepted principles. He makes a suggestion which we do not remember to have met with before, and which commends itself equally to the sanitary worker and to the individual who regards a cemetery from the point of view of sentiment. "In view of the evils which in former times have undoubtedly arisen from the practice of intramural sepulture, and also because the erection of houses near a cemetery interferes with the free play of air around and over it, it is desirable that the site of the cemetery should be in a neighbourhood in which building is not likely to take place, and also that so far as practicable a belt of ground should be reserved between the graves and the nearest land on which a house may be built, in order to obviate to some extent the risk of contamination of ground-air and subsoil water with decomposing matters. This is especially necessary where houses are constructed with cellars. It is, therefore, highly desirable that interments should not be made up to the extreme edge of the cemetery, and it would be possible without great waste of space to reserve in all cases a strip of ground free from interments, fifteen to thirty feet in width, around the whole cemetery on the interior of the boundary fence. This strip would afford room, on the inside, for a gravel or asphalte walk to give access to all parts of the cemetery, and on the outside next the fence to a belt of shrubs or trees, the rootlets of which penetrating the soil would arrest and assimilate any decomposing matters percolating to the exterior of the cemetery."

Faversham (Urban).—This is a report of an inspection made by Mr. W. H. Power, in 1880, to ascertain what had been done in this district by the sanitary authority since a previous inspection in 1875. The first inspection disclosed many shortcomings, and the second inspection showed that while some things had been done by the sanitary authority in the intervals of the inspections, other things had been left undone. But what is to be expected from a sanitary authority which does not, as we learn from Mr. Power, know, as it ought to know, the sanitary circumstances of its own district (possibly does not wish to know)? We must be thankful, then, for the smallest indications of improvement, hoping that such will serve to make more and more prominent to the ratepayers the shortcomings of the administration.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Halifax.—The medical officer of health for Halifax (Mr. Daniel Ainley) has presented to the Sanitary Committee of the Corporation a report on the recent severe localised outbreak of scarlet fever in his district. The report is not dated, but it appeared in the *Halifax Guardian* of Jan. 29th, and at the time of its presentation, and during the month, 319 cases of the disease, of which thirty-three were fatal, had occurred within a limited locality of the borough. Five deaths only from scarlet fever, it is stated, had been registered in the borough in the month of December. The great outbreak of the malady appears to have happened in the course of the first three days of January, and as "nearly every one" of the cases obtained milk from one milk-dealer, suspicion was early excited as to this article of food forming the medium for the dissemination of infection, a suspicion apparently strengthened by the failure to discover any other probable common source of infection. This suspicion was seemingly confirmed subsequently by finding that the family of a man in charge of and whose duty it was to milk certain of the cows from which the milk-dealer obtained a portion of his supply had scarlet fever in his family, and that he was in such close relation with the sick as, in Mr. Ainley's opinion, to make it certain he had been the medium through which the milk had become infected. Moreover, the manifestation of the infection of scarlet fever in this attendant's family had preceded, it is inferred, by at least three days the outburst in the borough. Mr. Ainley thinks he establishes a reasonable probability that the infection of the disease was, as he believes, distributed through the infected milk. But the details he gives as to the relations of the several cases of scarlet fever to the implicated milk, and the times of occurrence of the cases of scarlet fever in the cow-attendant's family—details upon which the validity of the whole argument depends—are curiously wanting in precision. Indeed, Dr. Britton, the medical officer of health for the Halifax (Rural) Combination of Sanitary Districts, within whose district the cow-attendant and his family live, and whose duty it has been to inquire into the circumstances of the prevalence of scarlet fever in the family, has already published data in respect to them, which appear to be irreconcilable with Mr. Ainley's conclusion. This outbreak has caused so much local anxiety that a numerous and influentially signed petition has been presented to the Local Government Board, asking for a special medical inquiry. The Board has assented to the petition, and Dr. Ballard has been instructed to make the desired inquiry.

Mexborough (*Urban*).—Our attention has been directed to a sentence in our notice of the Medical Officer of Health's Annual Report for 1880, for this district, which appeared in THE LANCET of the 12th inst., and which contains an unfortunate misprint. The words "privies constructed *without* drains" should read "privies constructed *with* drains." We entirely agree with the official report of the Local Government Board on this subject, in condemning the use of drains in privies.

THE TOTTENHAM LOCAL BOARD.

For some little time back the Tottenham Local Board has shown an excellent example to the Local Boards in the suburbs of London by the steady care with which it has carried out its duties, and the excellent effect their due performance has had upon the sanitary condition and general health of the district. We greatly regret to find that indications are being manifested of a tendency to fall off from the standard that this Local Board has maintained. At a recent meeting of the Board the medical officer's annual report was presented. The report would seem to have given a faithful account of the sanitary state of the district and its general health condition, and after its reading, as customary, we believe, a motion was made and seconded that 2000 copies of the report should be printed and put in circulation. Whereupon an amendment was proposed, on the ground that there were statements in it "likely to create a very great deal of prejudice against the board's officers," that the report should be "amended and revised," that is to say from what followed, purged of everything that it was most desirable that the ratepayers should know, before being printed. This amendment was carried by a majority of one, and the Local Board will therefore "amend" the report so as to make it palatable to the ratepayers and themselves. Tottenham used to have a Citizens' Sanitary Association which once did excellent service in a somewhat similar contingency. Let us hope that it still exists, for it would be deplorable if the Local Board were to be allowed to lapse into that neglectful state of sanitary administration which, not many years ago, excited so much prejudice amongst outsiders as to the health-condition of the district.

NOXIOUS VAPOURS.

The Report of the proceedings for 1880 of the Manchester Association for Controlling the Escape of Noxious Vapours and Fluids from Manufactories, although of the briefest, contains several interesting particulars. The Association is so disappointed with the prospects of general legislation on this subject, that they raise the question whether Manchester and Salford should not endeavour to obtain local legislation, by private Act, if the probabilities of general legislation do not quickly improve. With regard to the mitigation of the smoke nuisance in November last they suggested to the Nuisance Committee of the Manchester Corporation that the prohibition of dense smoke should be made *absolute*, instead of so many minutes in the hour being allowed. They found, however, that this suggestion had been anticipated by the Committee and was already acted upon, but the Committee had found it desirable to proceed cautiously in carrying it out. Salford does not appear to have had the same lively sense of dealing with the smoke nuisance as Manchester. Reference is made to the movement started in the metropolis with the object of trying to abate London fogs; and it seems, from a communication from Chicago addressed to the Association, that even the new-world city is occupied with the question of abating smoke nuisance.

FULHAM SMALL-POX HOSPITAL.

The public meeting to which we referred in our last week's impression as about to take place at the Subscription Rooms, Tattersall's, with respect to the small-pox hospital at Fulham, was held as announced, Mr. Lammin, the Fulham representative of the Metropolitan Board of Works in the chair. The course pursued was that which we had foreshadowed. A deputation was appointed to wait upon the Metropolitan Asylums Board and the Local Government Board, and urge that the number of small-pox patients to be received into the hospital should not be augmented, as was proposed by the Metropolitan Asylums Board. A committee was also formed to further the objects of the meeting. A letter from Mr. Francis Godrich, describing the influence which, in his opinion, the hospital exercises upon its neighbourhood, was read to the meeting. A public meeting has also been held at Chelsea on the same subject, Mr. J. B. Firth, M.P., presiding, and a plan of procedure was decided upon similar to that which had been determined by the previous meeting at Tattersall's. In the course of the meeting Mr. Firth remarked that blame was being cast upon the Asylums Board, but that the local authorities must take the blame to themselves for not having done their duty.

An outbreak of scarlet fever in the Toxteth Park district, adjoining Liverpool, is attributed to the dissemination of the infection of the disease through a milk supply. It is further reported that although it was known that scarlet fever existed on the dairy premises, and cases were occurring among the customers of the dairy, no proper precautions were taken to prevent mischief from the milk distributed, out of consideration for the dairyman's business, as if it were any part of his business to distribute scarlet fever! A local journal regards, however, this further report "as *almost* incredible."

Dr. Collum claims from the Lower Thames Valley Main Sewerage Board *thirty* guineas for services rendered to it. The Board have replied to the claim by voting a sum of *five* guineas, which Dr. Collum has properly refused to receive. The Board, however, adheres to its decision; having lavished thousands of pounds over its legal expenses, it seeks to establish a reputation for economy by practically repudiating its medical expenses.

It would appear that the Preston Board of Guardians and the Preston Corporation are squabbling about their respective duties in dealing with cases of small-pox, the population of the town meanwhile (whose protection from the disease they are mistakenly presumed to have in view) being left a prey to the contagion.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The registered mortality showed a further marked decline last week. In twenty of the largest English towns, estimated to contain in the middle of this year a population exceeding seven and a half millions of persons, 5569 births and 3347 deaths were registered last week. The births exceeded by 383, and the deaths by only 90, the average weekly numbers during last year. The deaths showed a further decline of not less than 745 from the high numbers returned in recent weeks. The annual death-rate in these twenty towns, which in the three previous weeks had been equal to 28·8, 31·0, and 28·0, further fell last week to 22·9. During the six weeks of the current quarter, ending on Saturday last, the death-rate in these twenty towns averaged only 25·9 per 1000, against 27·6 and 28·5 in the corresponding periods of 1879 and 1880.

The deaths in the twenty towns referred to the principal zymotic diseases, which had been 390, 373, and 366 in the three previous weeks, further declined last week to 316; of these, 71 resulted from scarlet fever, 71 from whooping-cough, 52 from small-pox, and 37 from fever, principally enteric. The annual death-rate from these zymotic diseases averaged only 2·2 per 1000 in the twenty towns, and ranged from 0·9 both in Oldham and Sunderland, to 3·3 and 4·4 in Liverpool and Nottingham. Scarlet fever showed the largest proportional fatality in Wolverhampton and Nottingham; while whooping-cough was most fatal in Leeds and Nottingham. Of the 23 deaths referred to diphtheria in the twenty towns, 17 occurred in London, 2 in Liverpool, and 2 in Portsmouth. The death-rate from fever (principally enteric) was highest in Newcastle-upon-Tyne, Nottingham, and Leicester. Small-pox caused 54 more deaths in London and its outer ring of suburban districts, while no fatal case of this disease was registered in any of the nineteen large provincial towns. The number of small-pox patients under treatment in the Metropolitan Asylum Hospitals, which had steadily increased from 77 to 617 in the fifteen preceding weeks, further rose to 683 on Saturday last. The number of new cases of small-pox admitted to these hospitals, which had been 114 and 234 in the two previous weeks, were 176 last week. The Highgate Small-pox Hospital contained 46 patients on Saturday last, against 30 and 37 at the end of the two preceding weeks; 16 new cases were admitted during the week.

The deaths referred to diseases of the respiratory organs in London, which had been 617, 702, and 606 in the three preceding weeks, fell last week to 408, and were no less than 127 below the corrected average number in the corresponding week of the last ten years; 269 resulted from bronchitis, and 91 from pneumonia. The annual death-rate from lung diseases (excluding phthisis) was equal to 5·4 per 1000 in London, while the rate from the same diseases in Liverpool was 8·7.

In the twenty towns last week the causes of 81, or 2·4 per cent., of the deaths were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths did not exceed 1·0 per cent. in London, while it averaged 3·7 per cent. in the nineteen provincial towns. No uncertified deaths were registered last week in Brighton or Newcastle-upon-Tyne, while their proportion was largest in Wolverhampton, Oldham, and Hull.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate averaged 24·3 per 1000 last week, against 34·7 and 28·9 in the two preceding weeks; this rate was 1·4 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 9·7 and 18·7 in Perth and Edinburgh, to 27·8 and 37·1 in Glasgow and Paisley. The deaths referred to the principal zymotic diseases in the eight towns, which had been 125 and 94 in the two previous weeks, further declined to 89 last week, and were equal to an annual rate of 3·5 per 1000, which was 1·2 above the average rate from the same diseases in the twenty English towns. The zymotic death-rate last week in the eight Scotch towns ranged from 0·0 and 1·8 in Perth and Edinburgh, to 4·3 in Glasgow and Leith, and 6·4 in Paisley. The fatal cases of scarlet fever in the eight towns, which had been 27 and 14 in the two preceding weeks, were 16 last week, of which 7 occurred in Glasgow, 3 in Edinburgh, 3 in Leith, and 2 in Greenock. The 28 deaths from whooping-cough showed a further decline of 6 from the numbers in the two previous weeks, and included 11 in Glasgow, 6 in Dundee, 4 in Paisley, and 3 in Edinburgh. The 16 fatal cases of diphtheria showed an increase, no less than 12 being recorded in Glasgow. The 8 deaths referred to "fever" were fewer than those in recent weeks. All the 7 deaths from measles, and 9 of the 14 from diarrhœa, were returned in Glasgow. The deaths referred to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy), in the eight Scotch towns, further declined last week to 200, from 348 and 261 in the two previous weeks. These 200 deaths from lung diseases were equal to an annual rate of 7·9 per 1000 of the population in the eight Scotch towns; the death-rate from the same diseases in London did not exceed 5·1. The greatest fatality of lung diseases in the Scotch towns occurred again last week in Glasgow and Paisley.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, although still markedly excessive, showed a further decline last week. The annual death-rate from all causes in the city, which had been equal to 45·7, 47·4, and 46·5 in the three preceding weeks, declined to 41·8 last week. During the first six weeks of the current quarter the death-rate in the city averaged no less than 41·4 per 1000, against 25·9 in London, and 23·1 in Edinburgh. The 267 deaths in Dublin last week were 30 fewer than the number in the previous week, and included 22, or little more than 10 per cent., which were referred to the principal zymotic diseases, against 37, 34, and 21 in the three preceding weeks. These 22 zymotic deaths in Dublin last week included 7 which were referred to fever (typhus, enteric or typhoid, and simple continued), 5 to scarlet fever, 4 to measles, 3 to whooping-cough, 2 to diarrhœa, 1 to diphtheria, and not 1 to small-pox. The annual death-rate from these zymotic diseases was equal to 3·4 per 1000 in Dublin last week, while it was only 2·3 in London, and 1·8 in Edinburgh. The deaths referred to fever, which had been 17 and 15 in the two previous weeks, declined to 7 last week, but were equal to an annual death-rate from fever which was more than four times as high as the average rate from the same cause last week in the twenty large English towns. The fatality of whooping-cough in Dublin showed a further decline last week, while the fatal cases both of measles and scarlet fever were more numerous. The deaths of elderly persons showed a further considerable decline last week, while those of infants had further increased.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE PUBLIC HEALTH ASPECTS OF THE IRISH CRISIS 1879–80.

The Dublin Mansion House Relief Committee have published a general report of their proceedings during the Irish crisis (as it is now the fashion to term the deplorable period of destitution through which the population of the sister island passed) in 1879–80. The story of the circumstances which led to that destitution, of the efforts made to relieve it, and of the part the Dublin Mansion House Committee performed in promoting that relief, is told eloquently and well. Altogether the report forms an invaluable contribution to the contemporary history of an eventful period, and it should have the careful reading of all English persons who would acquire a competent knowledge of the terrible crisis which Ireland has barely escaped from, and who would form a true judgment upon the matters which concern the future social condition of that island which are now impressed upon the public attention. The medical elements of the report, particularly the portions contributed by Dr. Sigerson and Dr. Kenny, were in the main commented on in the columns of THE LANCET at the time they were communicated to the Committee. From the information then before us we considered that the health aspects of the distress were of graver moment than appeared to be generally regarded by our contemporaries. We must confess, after reading this report, that we rather underrated than overrated the consequences from the public health point of view of this great disaster. The Committee lament that English sympathy should have been so largely warped in its consideration of the terrible miseries which the Irish population has so recently undergone by the political questions relating to Ireland, which were forced upon their attention at the same time, and it is to be feared that similar reasons may deter many from seeking to inform themselves at the present time of the real nature and extent of that misery. But we trust that this will only be in a very limited degree the case, and we would commend to all who take a thorough interest in the well-being of their fellow-men a perusal of this report. It possesses a terrible enthralment, and the general reader will not rise from its perusal without an acuter sympathy for the distressed in the sister island; the medical readers without thankfulness to this committee, and cognate committees, by whose exertions we were saved—barely saved, it may be—but saved from a repetition of the horrible scenes of the famine of 1846-47.

THE MONSALL FEVER HOSPITAL, MANCHESTER.

The Monsall Fever Hospital, Manchester, is, in reality, a detached section of the Royal Infirmary of the city. The trustees of that institution are required, we believe, by the deed of their appointment, to maintain a certain number of beds for infectious diseases, and out of this portion of their responsibilities has grown the large infectious disease hospital at Monsall, in the outskirts of the city. But the trustees have not contented themselves with providing hospital accommodation for the cases of infectious disease sent in ordinary course to the General Infirmary, but have also become the purveyors of such accommodation for the sanitary authorities of Manchester and Salford, and numerous other sanitary authorities in the environs of the city and neighbouring town. The trustees, in taking this course, had in view the facilitating the isolation of cases of infectious disease in hospital under unusually favourable circumstances, to wit, the use of a hospital for sanitary purposes which was organised and administered by the body responsible for the organisation and administration of the Royal Infirmary. We regret to learn that the project has failed in one very important particular. The charges made to the several sanitary authorities who have decided to benefit by the Monsall Hospital have proved to be fixed at so low a rate as to leave the trustees of the Royal Infirmary considerably out of pocket for its administration. The subject is now under the serious consideration of the trustees, and it is to be hoped that a readjustment of charges may be possible, and the original project of the trustees in regard to Monsall carried out without detriment to the funds of the parent institution.

PREVENTABLE DISEASES.

Dr. Smart has been lecturing in Edinburgh before a highly appreciative audience on "Preventable Diseases and their Causes." The lecture was one of a series of "Health Lectures for the People," and was delivered in the Free Church Assembly Hall. Dr. Smart described a preventable disease as one which arose or spread in consequence of the wilful, careless, or ignorant violation of those laws the proper observance of which we know to be necessary to the preservation of health and to avert the spread of disease. He next gave statistical details showing the great loss of life and the vast amount of sickness caused by the principal zymotic diseases, and explained the theory of zymosis. He dwelt also upon the nature of infection and the means necessary for preventing the spread of infectious diseases, and expressed the opinion that local authorities should be entrusted with a discretionary power of compulsory removal. "This discretion," he added, "would never be abused." In illustration of the wide-reaching play of infection, he referred to cases of small-pox imported into Edinburgh from London. He referred also to the proposition to convert the buildings of the old Royal Infirmary, Edinburgh, into a hospital for infectious diseases. Indicating the wide use he would have made of infectious-disease hospitals, he stated that the late Sir James Simpson had expressed his determination to be treated in hospital in the event of his suffering from an infectious disease. The lecture occupied an hour and a half in delivery, and was frequently interrupted by the applause of the crowd which filled the hall.

THE SOCIETY OF ARTS "SANITARY" MEDALS.

The Society of Arts propose to give a series of silver medals for plans showing the best Sanitary Arrangements in houses built in the metropolis, such plans to be exhibited in the Society's Rooms, Adelphi, in June, 1881, and to be sent in on or before May 12th, 1881. We forbear referring to the proposition in greater detail until we obtain some explanation of the following extraordinary statements in the prospectus. The judges in the competition, it is said, will be guided in considering their award "by the suggestions of plans for main sewerage, drainage, and water-supply, made under the Public Health Act, 1875." We thought ourselves tolerably familiar with the Public Health Act, 1875, but we confess this puzzles us, and what follows in a foot-note puzzles us still more. A foot-note to the words quoted above reads—"The Public Health Act has been revised to 1878, and published by her Majesty's Stationery Office. Price, with plans, three shillings." That the revision of public Acts should be handed over by the Legislature to the Stationery Office and issued with plans, is indeed a startling bit of news. The Society of Arts is, however, responsible for it; and we would advise intending competitors to ascertain if the Society really knows what it is about before expending time and trouble on the competition.

THE PARKES MUSEUM LECTURES.

Mr. Rogers Field, M.I.C.S., has been lecturing at the Parkes Museum on house drainage. By voice, experiment, and drawings he endeavoured to bring his great knowledge on this subject within the reach of the most ordinary capacity, and strange, but most hopeful to say, he spoke as if he fully believed it to be within the limits of possibility that builders and their employers might with due patience, and in the fulness of time, be taught the principles of correct house-drainage. True, he told a quite fresh story of a builder who prided himself on laying socketed drain-pipes, by laying them loose in the sockets, discarding packings of cement or other material, not only as useless, but positively harmful. This surely must have been a near relative of the man, if not the man himself, who has tickled the economy of his employers by using simple "butt" pipes for house drains, placing them merely end to end, and adapting them to curves by the simple process of partial junctions. It may also be that ingenious builder who, improving upon engineers' notions, lays all his S-traps horizontally. With admirable clearness and distinctness Mr. Rogers Field set forth the principles of a perfect system of house-drainage, teaching, however, not only what should be done to secure one, but what should be avoided.

At the last meeting of the Public Health Committee of the Edinburgh Town Council, the medical officer stated that the epidemic of scarlet fever, which had been prevailing in the city, is now steadily decreasing. Several owners of houses which had been found to be in an insanitary condition were ordered to have the premises put in a proper state of repair or to shut them up. In view of the increase of the small-pox epidemic in London, instructions were given to have a ward prepared in the Canongate Hospital for the reception of such patients, in the event of an outbreak of the disease in Edinburgh. No cases of small-pox have yet been reported in the city.

A short time ago attention was directed to the circumstance that several deaths had taken place in Glasgow from typhus fever, caught while "waking" the body of a person who had died of the same disease. The medical officer of Govanhill reports a death from scarlet fever, the disease having been contracted under precisely similar circumstances. The clergy might very properly use their influence to put a stop to the absurd and dangerous practice of "waking."

The Seamen's Hospital.—Lord Northbrook presided at the annual court which was held at Willis's Rooms on the 9th inst. The chief feature of interest was the presentation of an illuminated address to Mr. Burdett, the late secretary. During the past year, in addition to the ordinary routine work of the hospital, a dispensary has been opened in Wells-street, London Docks, for the benefit of sick sailors. Severe cases are at once sent from the dispensary to the hospital, and this plan has been found to work most satisfactorily.

THE SERVICES.

SIR FREDERICK ROBERTS AND HIS MEDICAL STAFF.

In congratulating Sir Frederick Roberts on his reception at the Guildhall on the 14th instant, we deem the occasion a fitting one for thanking him for the ungrudging manner in which he has at various times recognised the services of the medical officers attached to his column, and also for publicly drawing attention to the assiduous anxiety he displayed regarding the state of his sick and wounded, and the careful supervision he exercised over the sanitary arrangements both of camp and hospital. The result was to render the medical officers attached to his column devotedly loyal to their general, and we may point with pride to many gallant deeds performed by the medical staff of General Roberts's force. One of the most conspicuous acts of bravery was performed by Surgeon Duke, I.M.D., on the occasion of the explosion of the first magazine in the Bala Hissar on Oct. 16th, 1879, and whilst there was every expectation of the second magazine also becoming exploded, Surgeon Duke, on hearing that some Goorkhas were lying wounded within the fortress, climbed over the walls and succeeded in carrying them out. At the time Surgeon Duke was exposed to cartridges which were exploding in all directions. He was assisted in rescuing the Goorkhas by Surgeon Simmonds and Surgeon-Major Bourke, who afterwards came up. Surgeon Duke was also mentioned in despatches by Major-General Roberts "for his unremitting attention to the wounded under a heavy fire" during the fighting on the days previous to the investment of Sherpore. Surgeon Coates, I.M.D., also distinguished himself by the way in which he, in conjunction with Major Hills, of the 28th Punjaub Native Infantry, defended the native Field Hospital at Sherpore during the final attack and attempted escalade by the Ghazis. Surgeon Lentz, I.M.D., was likewise mentioned in despatches for his conduct under fire. On one occasion he had to cross a hill to attend to some wounded men, being exposed in his passage to a heavy fire the whole time. Similarly we record how Surgeon-Major Catkins, I.M.D., attended to the wounded in the fighting line. The above instances at any rate show that the surgeon is exposed to equal risks with those of his "combatant" brethren.

Again, Surgeon Simmonds, I.M.D., on the occasion of the march of reinforcements to aid Colonel Money when the Ghilzais were attacking him on the Shutargarden, took charge of the heliograph, and rendered essential assistance, as there was a paucity of signallers with the small column. This assistance was promptly acknowledged by General Roberts publicly thanking him before his regiment on the return march.

We must not omit to mention Surgeon Andrew Duncan, who was dangerously wounded at the time of the first assault on Cabul. This officer received his wound whilst standing by the side of General Baker, during the severest part of the engagement. We are pleased to be able to report that Dr. Duncan has now recovered from the effects of his wound, and that he was able to be present on Monday night at the Guildhall banquet. Others of the Medical Staff, however, were less fortunate. The death of Surgeon-Major Porter was one of the greatest losses incurred during the campaign; and the order published by Sir F. Roberts on the occasion fully testified how the officers and men had lost a friend whose skill was beyond question, and whose kindly disposition endeared him to all. A few days after Surgeon Porter's death Surgeon Keith died from pneumonia, the effects of constant exposure to the snow and frost during the anxious days of the investment of Sherpore. These facts, which only represent a tithe of the gallant and important services performed by the Medical Staff under Sir Frederick Roberts, testify, however, to the response given by this department to his just and generous treatment. In this respect the conduct of Sir Frederick Roberts stands in favourable contrast with that of many other general officers, who, after being greatly indebted to the indefatigable exertions of their Medical Staff, have subsequently ignored their claims for distinction or reward.

MEDICAL OFFICERS' MESSES.

We trust that the Army Medical Department will soon have clubs or messes in the various home garrisons. No arguments are needed to prove how valuable such establishments are to the *morale* of the Department. Quite apart from other advantages, the social intercourse of the medical officers with each other is very important. What has been done at Aldershot may be effected elsewhere, and we hope soon to be able to record the opening of similar institutions in our English garrisons. From small beginnings great things grow, and we hope the Secretary of State for War will do his part in aiding by a money grant these much needed Institutions.

NURSES FOR THE TRANSVAAL.

The War Office have arranged for the despatch of a lady-superintendent and three trained nurses from the Royal Victoria Hospital, Netley, by the mail steamer of the 18th, to Natal, for employment in the Base Field Hospitals. The Director-General, Army Medical Department, at the commencement of the Boer campaign suggested that a party of trained nurses should be sent to the Transvaal; but Sir George Colley decided that the ones he had engaged, locally assisted by the sisters from Bloemfontein, would be sufficient for the war. Now, however, that the campaign has assumed larger dimensions, an addition of thoroughly skilled and trained nurses will be a valuable accession to the medical staff.

A reinforcement of medical officers and Army Hospital Corps, with large supplies of medicine, surgical stores, equipments, and medical comforts, will be sent to the Transvaal by the troopships leaving early next week for Durban.

ARMY MEDICAL DEPARTMENT.—Brigade-Surgeon Andrew Semple, M.D., has been granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major Thomas Moriarty, M.D., has been granted retired pay; Surgeon Denis James O'Flynn, M.D., half-pay, resigns his commission.

Surgeon-Majors J. H. Robotham, J. Middleton, J. E. P. Aitchison, and Surgeon T. J. Gallwey, Army Medical Department, are on passage home from India in H.M. troopship *Malabar*.

Surgeon-Major C. Haines, A.M.D., has been ordered home to England on medical certificate for six months, and is pronounced unfit to do duty with troops on the voyage.

Surgeon-Major J. Cody, Bombay Medical Service, has been appointed secretary to the Surgeon-general with the Government of Bombay.

MILITIA MEDICAL DEPARTMENT.—Surgeon Thos. Wm. Spink Locke, West Suffolk Militia, to be Surgeon-Major.

ADMIRALTY.—Surgeon William Algeo has been promoted to the rank of Staff Surgeon in Her Majesty's Fleet, with seniority of 7th February, 1881. The undermentioned have been entered as Surgeons in Her Majesty's Fleet, with seniority of 2nd October, 1880:—William Joseph Christie, M.B.; John Jeffreys Dinnis, M.D.; George Frederick Wales; Malcolm Vincent Stace.

The following appointments have been made:—Staff Surgeon Thomas O. Sullivan to the *Duncan*, in lieu of a Surgeon; Staff Surgeon H. Beaumont to the *Arab;* Staff Surgeon Robert Grant to the *Champion*, temporarily; Surgeon G. H. S. J. Bankier, M.D., to the *London*, vice White.

ROYAL NAVAL ARTILLERY VOLUNTEERS (Liverpool Brigade).—William Little, Esq., to be Honorary Surgeon; Frank Thomas Paul, Esq., to be Surgeon.

THE LONDON FEVER HOSPITAL. — Lord Devon presided at the annual meeting of governors of this instituton, held last week at Freemasons' Hall. The report, read by Dr. Cayley, showed that 1011 cases of fever and diseases of a contagious character had been treated in the hospital during the year, but the amount of support afforded to the institution, notwithstanding the appeal made for funds, had been so small as to create fears that the future usefulness of the hospital might have to be curtailed. It is as remarkable as regrettable that the whole of the contributions for the year amounted to only £660. Mr. Hugh Owen, the hon. secretary, retired after twenty-three years' services, Mr. M. D. Chalmers being elected to fill the vacancy. Earl Devon was again elected president, and thanked for his services.

THE HUNTERIAN ORATION.

This biennial discourse in memory of John Hunter was delivered on Monday last in the theatre of the Royal College of Surgeons, by Mr. Luther Holden, late President of the College. The large theatre was crowded with members and visitors. The President, Mr. J. E. Erichsen, F.R.S., was in the chair, supported by the Vice-Presidents, Messrs. Erasmus Wilson and Spencer Wells, and most of the members of the Council.

Mr. Holden commenced his oration with the well-known words, "Let us now praise famous men and our fathers that begat us." He could find, he said, no better words than these wherewith to invite his audience to welcome the theme which had brought them together that day to do honour to the father of English surgeons, whose fame was so high that we but honoured ourselves in bearing witness before the world how much we honour him as loyal disciples in self-devotion and the pursuit of truth. Some natures, it was true, were disheartened by the contemplation of the great achievements of genius which mapped out the history of our race, and here and there an indolent man might be found who has buried his own talent because it was not ten. Though this temper of mind was happily rare in the profession of which his hearers were members, which daily brought them face to face with the painful aspects and emergencies of real life, it was nevertheless very desirable that they should always keep before them such brilliant examples of successful genius. To the striving and earnest man they were full of encouragement; not only did they urge him on the path of common duty, but they raised him, as it were, to an eminence from which he might overlook the past, and by seeing the results of the aspirations of his predecessors, assure himself of the reasonableness of his own. As English sailors were proud of Nelson, English soldiers of Wellington, English poets of Shakespeare, English physicians of Harvey, so were English surgeons proud of Hunter.

The orator proceeded:—"I shall claim from you some recognition of my especial attachment to my theme if I can contribute a new item of information towards that part of Hunter's history which is the most obscure. We are told by John Hunter's biographers, most of whom seem to have copied from each other an unpardonable inaccuracy, that John Hunter, the father, died when his son John was but ten years old, and that before and after that time, up to the date of his coming to London, he led a completely idle life, only broken into by a short and unsuccessful apprenticeship to a cabinet-maker in Glasgow, who had married his sister, and to whom he was sent for the purpose of helping him out of some embarrassment in his trade. His father was, we know, within two years of fourscore when he died; and the partiality which he must naturally have felt in his declining years for the high-spirited son of his old age is represented as the cause of his having dealt too leniently with him, to the neglect of his real interests. The outlines of the picture are easily sketched: up to ten years the darling of a decrepit father, after ten the pet of a widowed mother, spoilt, humoured, encouraged in idleness, unchecked, untrained, uneducated; such, I say, are the outlines, leaving a blank to be filled in according to the fancy of the biographers, who have rather dwelt upon this extraordinary contrast between the boy and the man—a contrast so complete and unintelligible that, if 'the boy is father of the man,' it requires a miracle to interpret it; and in the miracle lies some of the charm of their story. Thus one orator writes, 'He seems to have led the idle life of a wayward, petted boy until twenty years of age.' Another depicts him as having 'up to twenty years of age, passed a life of idleness, dissipation, and amusement, with no definite object, no settled employment—his highest occupation that of a cabinet-maker, and his education entirely neglected, threatening to destroy all stability of character and all capacity for sustained exertion.' And the same account is the *textus receptus* on the Continent. Thus Fischer, in his 'Chirurgie vor 100 Jahren,' says, 'Hunter was destined by his father to be a ship's carpenter, and in his twentieth year, when he came to his brother in London, he could scarcely read and write.' Again, one of the latest and the most eloquent of the Hunterian orators has thus expressed the same story:—'In the first twenty years of his life he appears to have had no inclination to science or to the arts that minister to it, or indeed to any intellectual pursuit. Had he succeeded in helping his brother-in-law, who was a bankrupt cabinet-maker, cabinet-making might have been the business of his life. Happily he failed; and then after two years more idleness, what was to be done?' Well, we all know what John Hunter *did*. He came to London to work under his brother William at anatomy; and the true history of the man, as he was known to his contemporaries, begins with the famous story of the dissection of the muscles of the arm, wherein he so satisfied Dr. William, at the very first outset, with his skill and proficiency, that he received at once the promise of his unlimited patronage, and in the very next year was engaged by him to prepare anatomical subjects for the public lectures, and to give instruction to the pupils. It is not necessary to point out to you, gentlemen, the significance of this fact, nor to remind you that it was not only the professional reputation of William Hunter, but even the advancement of anatomy in England, that was made over to John Hunter without hesitation......" Continued searches proved that John had received the same schooling as his brother, Dr. William Hunter, and that he had matriculated at the University of Glasgow in Nov. 1745. Mr. Holden was inclined to distinguish John Hunter the human anatomist, from the comparative anatomist, and to say that we had in him an admirable example of the method of the two studies, and of the manner in which they should both be pursued for the advancement of medical science. The term "comparative anatomy," strictly taken, included human anatomy, and if human anatomy had become a science on its own account it was due to the fact that when the anatomist investigated his own body the importance of the subject and the interest of his inquiries made this study paramount; and were it not for the unquestioned pre-eminence of man and the habit which he naturally had of considering himself the centre of the universe, this might scientifically be called an accident. After paying a tribute to the genius of Aristotle, the orator proceeded to speak of the anatomy of Galen and his school, and of all anatomists who preceded the Renaissance, as well as of many who lived to see the sciences reviving and revived. Comparative anatomy, he pointed out, actually stood in the way of human anatomy so as to obstruct it. Human bodies were so difficult to procure for dissection, and the study of them consequently was so rare, that the necessary observations were, as Aristotle said, supplemented from the dissection and investigation of the corresponding organs of the lower animals. As illustrating the relations of human and comparative anatomy, Mr. Holden stated that the physicians in attendance on the Margrave of Baden-Durlach, disputed among themselves as to the position of the heart in the thorax of the Prince, one of them contending, with Galen, that it lay in the middle, the rest being bold enough to affirm that it was on his left side. As this unfortunate doubt assumed the aspect of a serious practical difficulty when it came to determining the precise spot on which should be applied the plaster which was destined to relieve the sufferings of the Margrave, it was decided to appeal to nature. A pig was therefore brought into the royal chamber and opened in the presence of the sick man. The position of the heart was demonstrated to him; if in a pig, therefore in a prince. His highness gave way before this argument, and the plaster was placed accordingly; while the physician, who still had the temerity to defend himself by drawing anatomical distinction between man and pig, was dismissed from the court. In remarking on the teaching of the present day, as painfully illustrated by the large number of rejections of candidates by examining boards, Mr. Holden was unwilling to impute this entirely to the severity of the examiners or to the remissness of the students. After a feeling allusion to the deaths of certain members of the profession since the last oration was delivered, especially those of Mr. Henry Hancock, a former orator and president of the College, and of Mr. G. W. Callender, the orator concluded by dwelling on the advantage of a classical training for medical students, stating that as an old teacher he found those pupils who had received a good public school training could be taught more in two months than others in six. He urged that the youths who were to be the future representatives of English surgery should not be looked upon as "symbols" of an inferior education.

In the evening the President and Council entertained a large and distinguished party at dinner in the library of the College. Among those present were the Lord Chancellor, Earl Granville, Sir R. Cross, the Bishop of London, the Dean of Westminster, and Mr. James Russell Lowell, the American Minister.

Correspondence.

"Audi alteram partem."

THE CHLOROTIC MURMUR.

To the Editor of THE LANCET.

SIR,—I regret that I erroneously associated Naunyn's name ith the chlorotic murmur. That the error is to some extent excusable is, I think, proved by the fact that such writers as Dr. Bristowe[1] and Dr. Fothergill[2] make the same mistake.

I unfortunately was not acquainted with the article in THE LANCET to which Dr. George Balfour refers me, or I certainly should not have mistaken his views as I have done. My statement of his views was based on the impression which I derived from the perusal of Chapter VI. of his "Diseases of the Heart." Taking that article as representative of Dr. Balfour's views, most readers would, I think, conclude, as I did, that he denied the arterial character of the basic murmurs in anæmia. His whole argument, as I read it, and the following passages in particular, tend towards that end.

"But if we can show, as I hope to do, that the cardiac portion of these murmur is not simply hæmic or purely functional in character, but is the product of an actual cardiac lesion, then we link blood disease with cardiac lesion in a very striking manner, and obtain the important pathological information that some cardiac lesions are certainly and permanently curable" (page 158). "But the venous murmurs which accompany chlorosis are for many reasons of very much less interest and importance than those heard in the cardiac area. As already mentioned these are systolic in character, and are most frequently heard in the pulmonary area, less frequently so in the aortic area, and most rarely in the mitral area" (page 159). "This so-called arterial murmur is, therefore, not arterial at all, but strictly auricular in its source" (page 160). . . . . . "In all febrile diseases, whatever their character, the sequence of the phenomena, as observed by myself, has been precisely similar to that observed in chlorosis. That is: first, we have had the venous hum; second, the auricular murmur, propagated into the pulmonary and aortic areas, either as an impure or prolonged first sound, or as a distinct systolic murmur; and, lastly and more rarely, a systolic murmur in the mitral area" (page 168). . . . . . "*The arterial murmurs are therefore not of independent origin* [the italics are my own], but are propagated from the mitral valve, which permits slight regurgitation between its segments, which are unable to close perfectly because the ventricular lumen is somewhat dilated" (page 169).

The exact mode of causation of the reduplicated second sound in cases of mitral stenosis is confessedly somewhat obscure. The very emphatic way in which Dr. George Balfour—for whose opinion on this and all subjects relating to the circulation I have great respect—expresses himself against the theory which I have adopted, makes me think that it is perhaps wrong. Still it is a view which is not without its weighty supporters. Thus Rosenstein, who writes the article on Mitral Stenosis in Ziemssen's "Cyclopædia,"[3] not only concludes that the aortic valves close before those of the pulmonary artery, but brings actual clinical proof of the fact, when he states, that the second portion of the reduplicated sound may be heard much more accentuated over the pulmonary artery than over the aorta. He says, "Geigel called attention to its frequency—(i.e., frequency of reduplicated second sound)—of occurrence in stenosis, and explains it by the unequal tension in the aorta and pulmonalis, which may prevent synchronous closure of the valves of the two vessels, since the aorta with its smaller contents contracts quicker, and thus closes its semilunar valves an instant before those of the pulmonary artery. The fact that the second part of the reduplicated sound may be heard much more accentuated over the ostium of the pulmonalis lends a great probability to the view that it is produced by the valves of this artery."

Sibson, too, in his elaborate article on Endocarditis in Russell Reynolds' "System of Medicine," in speaking of doubling of the second sound in connexion with mitral murmurs, says: "On the second day there was doubling of the second sound over that (i.e., the pulmonary) artery. The second sound was louder than the first, and this proved that the later sound was the pulmonic, the earlier the aortic, sound. In this instance the doubling of the second sound, which lasted to the 60th day, disappearing on the 69th, *was due, I consider, to the longer time occupied by the right ventricle than the left in emptying itself, owing to the resistance to the flow of blood through the lungs.*"[4] (The italics are my own.)

Hayden, in his work on "Diseases of the Heart and Aorta," states: "Where the second sound is reduplicated in connexion with mitral stenosis, the element deranged is most likely that produced in the pulmonary artery, the entire pulmonary system and the right chambers being engorged by obstruction at the mitral orifice. *In the effort to overcome this obstruction the systole of the right ventricle is protracted and the reaction of the pulmonary artery proportionately postponed.* (The italics are my own.) The reaction of the aorta is, on the other hand, in mitral stenosis, most probably anticipated where the left ventricle is reduced in capacity, as always is the case where mitral or aortic reflux does not co-exist. Hence it is likely that in simple mitral stenosis two causes of doubling of the second sound are in operation—namely, diminished capacity of the left and dilatation of the right ventricle."[5]

To some of the general statements I have in my lecture made, exceptions, of course, occur. Thus, for example, the tone of the same murmur may occasionally differ at two different parts of the chest wall; the inorganic murmurs of anæmia are sometimes associated with important disturbances in the heart and circulation, &c.

In speaking of the altered character of the first sound in mitral stenosis I say that it is due to the small amount of blood which gets into the left ventricle, and omit to mention as a cause the altered condition of the mitral cusps. Students who have attended my lectures, and who know that I am in the habit of teaching that the chief cause of the first sound is the tension of the auricular ventricular valves, will readily understand that this is an unintentional omission. Others might from the statement think that I am one of those who advocate the purely muscular, as opposed to the valvular, character of the first sound.

With these explanations I must leave the lecture to receive from the profession such measure of approval or disapproval as it may deserve.

I remain, Sir, yours very truly,

Edinburgh, Feb. 7th, 1881. BYROM BRAMWELL.

ANIMAL LIGATURES.

To the Editor of THE LANCET.

SIR,—The interest so generally felt in this subject will, I trust, justify reference to two eminent authorities, one of which is probably not generally accessible to your readers. Professor S. D. Gross,[1] in his chapter on Diseases and Injuries of the Arteries, records that "animal ligatures were first introduced to the notice of the profession by Dr. Physick early in the present century, and they have ever since been occasionally employed by different practitioners, chiefly American." Luigi Porta teaches: "Amongst the substances applicable to the ligature of arteries, gut-cord is without doubt the strongest and the most homogeneous."[2] He gives the results of eighty experiments to bear out this statement, and expresses himself confidently on the absorption of the animal ligature.

I am, Sir, your obedient servant,

Birmingham, Feb. 12th, 1881. SAMPSON GAMGEE.

THE UNIVERSAL HYSTEROPHORE.

To the Editor of The Lancet.

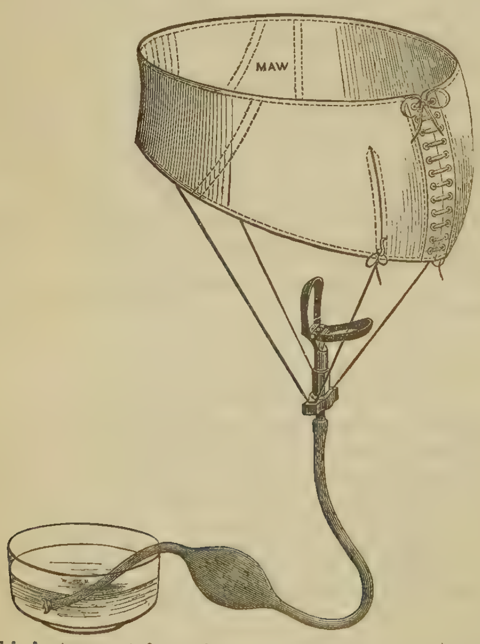
Sir,—I would ask a little space in your invaluable journal in reference to a hysterophore or pessary which I have had made by Messrs. Maw, Son, and Thompson.

I have been much disappointed with the pessaries in common use, and in some cases have found those which are considered the most efficient to be entirely useless, and in cases where they did prove of service, that they were very deficient in many most important points.

The hysterophore is made of vulcanite, and consists of a stem and two blades.

The stem is two inches and a quarter in length, with a tube running through the centre; to the upper end the blades are attached by hinges, which blades can be separated and approximated at pleasure by means of a screw, which forms part of the lower end of the stem. Around the lower end of the stem is a movable cylinder, through which pass two caoutchouc cords, one opposite the other. The blades are concave and elongated. Each blade has a large hole in the centre, which adds to the lightness, and permits the escape of injected fluids. One blade is two and a half inches in length, and one inch longer than the other, and is immovable. The shorter blade is of the same formation, and is so constructed that by the action of the screw in the stem it is made to approach or recede from the longer when desired.

The hysterophore, when closed, is lemon-shaped. The smaller blade, with its rounded edges, falls slightly into the concavity of its fellow. The cords are hooked on by means of strong elastic bands. Each band is perforated with three holes, each hole one inch apart, and through either of these the hook passes. The other ends of the cords are passed behind, and attached in like manner. To the lower end of the stem of the hysterophore the silver point of an india-rubber syringe can be attached, so that injections can be applied to the uterus and vagina at any time, without disturbing the hysterophore. The woodcut represents the syringe as attached to the instrument.



This instrument is made in three sizes; also a modification in three sizes, which is essentially the same, with two exceptions—viz., (1) the blades are of equal length, and (2) the blades are equally movable.

The instrument, as first described, is intended to rectify any flexion or version of the uterus. If there is anteflexion or version, this is rectified by introducing the hysterophore so that its long blade with its convex surface will be anterior. This blade that is fixed, and longer than the other, passes up in front of the cervix and body of the uterus, and thus raises the uterus to its natural axis in the pelvis, and is supported on the opposite side by the opposing blade. At the same time the cervix is free, and subjected to no undue pressure. In retroflexion or version the long blade is passed up in like manner over the posterior surface of the cervix and body, and similarly in the lateral displacements. The hysterophore, with its blades of equal length and mobility, is intended for prolapsus uteri.

I have found the advantages embodied in this hysterophore to be the following:—1. That by means of one instrument all displacements can be adjusted. 2. The instrument always presents a convex surface externally. 3. In marked cystocele or rectocele, more especially where the vulva is large and yielding, and in aged women where there is senile decay and general absence of adipose tissue, it will be impossible to get even a Hodge to act. 4. The attached elastic bands, which are hooked on in front and behind to the abdominal binder, yield at every movement of the body and inspiration, thereby permitting all natural movements of the uterus; thus avoiding all danger of violence, which unyielding supports would cause. 5. On account of the beveling of its edges, the instrument is free from the risk of nipping the parts in extraction. 6. By the use of the syringe injections can be thrown up so as to come in contact with the external surface of the uterus and internal surface of vagina, thereby keeping the parts healthy, and free from the offensive discharge, liability to inflammation, and ulceration. Where congestion and ulceration do exist with displacement, the hysterophore can be worn with comfort, and the uterus kept in its proper axis, while the curative treatment may proceed uninterruptedly.

I remain, Sir, yours faithfully,

John McG. MacCormac, L.R.C.P. & L.R.C.S. Ed.

Lindley, Huddersfield, Jan. 26th, 1881.

EDINBURGH.

(*From our own Correspondent.*)

At a recent meeting of the Royal Medical Society a patient was shown on whom an interesting Taliacotian operation had been performed, with a successful result. About eight years ago the patient sustained a severe burn of the head, which destroyed the whole of the scalp, ear, and outer table of the right side of the cranium. In process of time the dead bone became removed; but owing to the great tension a satisfactory cicatrix could not form, and the young epidermis broke down and ulcerated continually. Skin-grafting on such an unhealthy surface was impracticable. To remedy this state of affairs the cicatrix was "rawed," two flaps were dissected from off the inner side of the upper right arm, and held in position with catgut sutures and collodion, while the arm was secured to the head and the whole incorporated in a suitable plaster-of-Paris apparatus. In eight days the flaps were cut free and the arm brought down. Subsequent progress was so satisfactory that the patient was exhibited with a soundly healed scalp, free from tension and with complete epidermic continuity.

It is stated that Dr. James Russell will be appointed Inspector of Anatomy, in place of the late Dr. Andrew Wood.

IRELAND.

(*From our own Correspondent.*)

Dr. MacCabe, Local Government Board Inspector, in his half-yearly report in respect to the South Dublin Union states that he has long been of opinion that both the North and South Dublin Workhouses, in reference to the accommodation they afford, are quite inadequate for the requirements of the destitute poor within the city of Dublin and the surrounding electoral divisions. He adds that in the South Dublin Workhouse on the 1st of January last the number of inmates was 3489, so that the building contained 84 in excess of the number which could be properly accommodated, having regard to cubic space and the reservation of certain wards as day-rooms only. Of the total number of inmates about 2500 are hospital cases, and aged and infirm people, classes amongst whom a high mortality might be expected to prevail, yet the death-rate during the past six months amounted to less than 33 per 1000, and was actually below the death-rate among the general population included in the Dublin Registration District during the same period. This fact, as Dr. MacCabe points out, affords striking evidence of the good sanitary condition of the workhouse.

In Kilmainham Small-pox Hospital there were 118 acute cases of this disease, and in addition 61 convalescent cases were received from the Hardwicke Hospital. Of the acute cases the mortality among those who bore vaccination marks was at the rate of 13·8 per cent., while of those in which vaccination marks were absent 90 per cent. died.

It has recently been urged in Belfast that a hospital for consumption and other pulmonary affections is much required in that town, in consequence of the large number of work-people engaged in flax-spinning, and who, from the nature of their occupation and their mode of life, are peculiarly liable to be attacked by phthisis. More especially is the want of an institution of the kind felt in consequence of a regulation of the Belfast Royal Hospital, which practically excludes phthisical patients—at all events, in the later stages of the disease—from the only general hospital in Belfast. This rule was adopted in consequence of the heavy expense of maintaining such patients, while the curative result was *nil*. It is true that a provident dispensary has been for some months in operation in Belfast, for supplying advice and medicine to applicants; but as there is no intern accommodation the amount of good done can only be of service in the very early stages of the disease. The Society for Providing Nurses for the Sick Poor has been of considerable use in these cases, and has visited and relieved many hundreds of phthisical patients.

A Local Government Board Inspector opened an inquiry at the Town Hall, Wexford, last week, in reference to the condition of the borough graveyards, it having been represented by the local medical officers that these burial-grounds were much overcrowded and dangerous to health. Dr. Pierce, sanitary officer, gave evidence to the effect that he had examined the several urban burial-grounds, that they were overcrowded, and that any further interments would be dangerous to the public health. The inquiry has been adjourned.

At a recent meeting of the Governors of Cork-street Fever Hospital, Dublin, the Registrar reported that although the number of admissions in typhus fever cases had steadily declined during the month of January, yet the disease was still very prevalent in the city and suburbs. Cases of small-pox are also again on the increase.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Thursday, 10th inst., a return relating to the superannuation of medical officers in Ireland was ordered to be printed. A petition was presented by Dr. Farquharson from the National Health Society against the proposed Guildford, Kingston, and London Railway.

On Friday Mr. Chamberlain stated to Mr. Ross that the Board of Trade were preparing a Bill dealing with the subject of druggists' measures. A petition was presented from the St. Saviour's District Board of Works praying for inquiry into the affairs of Guy's Hospital. Mr. Woodall brought in a Bill to provide for the better education of blind and deaf-mute children.

On Monday a petition for redress in connexion with the Indian Army Medical Department was presented from Arthur P. Holmes. A petition was presented from Athy Union, for alteration of the law of poor relief in Ireland. Mr. Tottenham gave notice that on Thursday he would ask the Chief Secretary to the Lord Lieutenant of Ireland, under what circumstances the claims of the Assistant Resident Medical Superintendents of the Irish Lunatic Asylums were overlooked in the recent appointment of the Resident Medical Superintendent of the Carlow Asylum; and whether the gentleman who received the appointment had any special qualifications justifying their supersession, or had ever served as an assistant in any lunatic asylum.

On Tuesday Sir William V. Harcourt, in answer to Mr. A. O'Connor, stated that a deaf and dumb boy, aged fifteen, who was sent to a reformatory in 1877 for five years, was now under instruction by an instructor sent from a deaf and dumb asylum.

On Wednesday the second reading of the Coroners (Ireland) Bill was further deferred to Friday.

Carlow Asylum.

On Thursday, in reply to Mr. Tottenham, Mr. Forster said the claims of none of the applicants for the appointment of Resident Medical Superintendent of Carlow Asylum were overlooked. They all received careful consideration, and the gentleman selected was already intimately acquainted with the asylum, from the fact of his having attended there during the official visits of his father, the late visiting physician, and having on several occasions discharged the duties of the late resident medical superintendent when that official was absent on leave. The question of the hon. and gallant gentleman seems to imply that some gentleman was superseded by the appointment that was made, but that was not the fact. The assistant resident medical superintendents have no claims to appointment as resident medical superintendent.

Obituary.

FERDINAND JENCKEN, M.R.C.P., &c.

ON the 5th inst. we briefly noticed the lamented death of this gentleman at Kingstown on Jan. 11th, caused by blood-poisoning in opening an abscess in the arm of a patient suffering from erysipelas.

Mr. Jencken had during his career been a contributor to several of our leading journals, his papers on "Atmospheric Dust" and "Modified Inoculation of Cow-pock for the Prevention of Rinderpest" having attracted attention at the time; whilst his treatises on "Cholera" and "Vaccination" may be consulted with advantage on these much-discussed questions. Early in life Mr. Jencken showed great aptitude for music, and whilst only eleven years old he dedicated a piece of his composition by permission to H.M. the Dowager Queen Adelaide. The deceased forms one of those instances which prove how much may be effected by mere determined industry. Born blind, and only partially able to use his sight after an operation for cataract, he persevered, and, despite the enormous disadvantage his physical defect entailed on him, not only obtained the Membership of the College of Physicians, but boldly entered into the sphere of literature, which it would have been thought needed eyesight to ensure success. Wiegand's "Birth of Man," the father of obstetric science, has been translated and annotated by Mr. Jencken, and was ready for the press at the time of his death; in addition, he has left a work on "Organic Life" as well as a translation of Madame de Staël's "Letters on England," which no doubt at some future day his family will place in the hands of the English public. We can but regret the loss of so valuable a member of our profession just at a period when he was ready to add to the literature of the day, garnered during years of study and experience—a further tribute to the great wealth of learning of which this century may be justly proud.

DR. JOHN DAVIDSON, C.B., INSPECT.-GEN. R.N.

DR. DAVIDSON died at his residence, Bosworth Lodge, Willesden-lane, on Jan. 31st, and was interred in the cemetery of Greenwich Hospital on the 5th inst., his funeral being attended by a number of his late brother officers.

The deceased gentleman entered the Naval Service in July, 1839, and was shortly after sent to China, where he was present at the captures of Canton and Chapoo, and throughout the operations on the Yangtse-Kiang river. In 1843 he was appointed surgeon to H.M.S. *Dido*, and in her served in Borneo. From 1850 to 1851 he was surgeon in charge of the Naval Hospital at Ascension, from which he returned with impaired health. At the commencement of the Russian war he was despatched to the charge of the Naval Hospital at Therapia, where he received promotion to the rank of Deputy Inspector-General in March, 1855, at the early age of thirty-eight years, continuing to serve there to the end of the war in 1857. His subsequent services were rendered at home, being Deputy Inspector of Haslar from 1859 to 1866, Inspector-General of Greenwich Hospital during 1867, and of Plymouth Hospital from 1868 to 1873, when he sought retirement from active service, on account of greatly impaired health, attributable to his duties.

Dr. Davidson was greatly esteemed in the Navy as a skilful surgeon and a sound physician, and as a liberal, honest, and generous man.

GEORGE H. AITCHISON, M.D. EDIN.

DR. AITCHISON was born in Kilmarnock, in 1845, and gave promise of achieving great distinction as a physician in Scotland. During his period of study in the University of Edinburgh he took the first place in the Latin and Logic classes, whilst his fluency of speech and breadth of judgment made him conspicuous in the debating societies in connexion with his Alma Mater. After obtaining his B.M. and C.M., Dr. Aitchison commenced practice in Yorkshire, but he soon returned to Edinburgh and took the M.D. in 1878, becoming a Fellow of the College of Physicians in the same year. He had scarcely, however, laid the foundation of a prosperous career when the symptoms of his fatal malady appeared, and frustrated all his hopes. It is believed that a poisoned wound received in the practice of his profession was the exciting cause of an illness which, after two years of suffering, terminated his valuable life.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following gentlemen had conferred on them, on the 10th inst., the degree of M.B.:—

Young, Arthur, Caius College.
Nichols, Frederick Peter, St. Catharine's College.
Gover, Henry John, Trinity Hall.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Feb. 10th:—

Cranstone, William Lefevre, Barrington-street.
Partrige, William Stroud, Newhall-street, Birmingham.
Humphreys, William Carr, Bank House, Bromsgrove.

The following gentleman also on the same day passed the Primary Professional Examination:—

Jennings, Charles Egerton, London Hospital.

THE salary of Dr. Porter, medical officer of the Bow district of the Poplar Union, has been increased to £150 per annum.

MR. W. F. FULLER, late Assistant Medical Officer of the Parish of St. Marylebone, has received a superannuation allowance of £80.

THE 13th inst. was observed in Manchester as Hospital Sunday, when collections were made in all the churches and chapels of the town. The proceeds of the collection have not yet been made known.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—In the list of gentlemen who were successful in the second professional examination of the above, and which appeared in THE LANCET of February 5th, the name "F. G. Marchment" should have been F. G. Maidment.

RIVERS CONSERVANCY.—Mr. C. N. Cresswell is to read a paper on this subject before the Society of Arts on Wednesday next, the 23rd inst. The paper will deal principally with the three important topics of Floods Prevention, Rivers Pollution, and Water Supply.

CHARING-CROSS HOSPITAL.—It is satisfactory to learn, from the report of this institution read at the annual meeting of the governors on the 9th inst., that the special appeal to the public put forth in the past year met with a generous response. The result of the appeal has not, however, been ample enough to warrant the council in bringing again into use the thirty beds they were, some months ago, compelled to withdraw from the wards, the expenditure (£16,113) still exceeding the receipts by £2680.

ROYAL FREE HOSPITAL.—The report read at the annual meeting of the governors of this hospital, stated the receipts from all sources last year to have been £15,610, the ordinary expenditure £9367; whilst repairs and other improvements had involved an outlay of £6705. The number of in-patients had been 1360; 1242 had been discharged recovered, and 88 had died. A festival dinner in aid of the funds would, it was announced, take place in the ensuing spring.

LONDON TEMPERANCE HOSPITAL.—The new buildings of the London Temperance Hospital, in the Hampstead-road, will be opened on Friday, March 4th, by the Lord Mayor, who, with the Sheriffs of London and Middlesex, will attend in state. The buildings, when complete, will hold fifty in-patients.

LONGEVITY.—The obituary column of a contemporary, on the 10th inst., gives the deaths of four females, whose united ages number three hundred and ninety years, yielding an average of ninety-seven years and six months to each. Their respective ages were 93, 94, 99, and 104 years.

FRENCH HOSPITAL AND DISPENSARY.—The thirteenth annual dinner in aid of the funds of this institution was held on the 12th inst., when the French Ambassador, M. Challemel-Lacour, presided, and a distinguished company assembled. The Lord Mayor, as one of the executive of the Hospital Sunday Fund, bore testimony to the efficiency and economy of the management of the hospital, and the *réunion*, at its close, was voted an undoubted success.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. Mr. E. B. Noden, late of Brixton, bequeathed £1000 to the Manchester Royal Infirmary, £500 each to the Cancer Hospital, Fulham-road, and the Brompton Consumption Hospital, £300 to the Royal Hospital for Incurables, £250 to Miss Marsh's Convalescent Home at Brighton, and £200 each to the London Hospital and St. Mark's Hospital. The Leeds General Infirmary has received a legacy of £19 19*s.* from the late Mr. McConnochie, and £50 from the workpeople of Messrs. Briggs and Co.'s Collieries. The Belfast Hospital for Sick Children has received £50 from "Subscriber." Messrs. Guinness have given £60 to Steevens' Hospital; and the trustees of Bishop Stearne's charities have handed a donation of £60 to St. Mark's Ophthalmic Hospital, Dublin. By the will of Miss M. V. Durell, late of Oxford, the Radcliffe Infirmary becomes entitled to £300. Miss Farme, late of Edinburgh, bequeathed £500 to the Edinburgh Hospital for Incurables. Miss Isabella Still, late of Aberdeen, bequeathed £50 to the Aberdeen Royal Infirmary.

ST. MARK'S HOSPITAL.—The annual meeting of the subscribers to St. Mark's Hospital, in the City-road, was held on the 10th inst., at the Mansion House. The annual report stated that during the forty years the charity had been in existence more than 43,000 sufferers, of both sexes and of all ages, had sought relief from their distressing and painful maladies, the greater part of whom had been either cured or sufficiently relieved to enable them to resume their labours. Over 2000 patients annually received the benefits of the hospital. As the demands upon it continued to increase without a commensurate increase in its income, the committee hoped that the charitably-disposed public would aid them in carrying on the good and benevolent work, which, up to the present time, had been so successful. The committee of management were unhappily unable to speak very cheeringly of the financial state of the hospital, as this year again the accounts showed a deficit of £767 10*s.* 4*d.*

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest*

ABBOTT, C. E., L.K.Q.C.P.I., M.R.C.S.E., has been appointed Medical Officer of Health to the Braintree Rural Sanitary Authority.

BLAKESLEY, H. J., M.R.C.S.E., has been appointed Assistant Medical Officer to the Leicestershire and Rutland Lunatic Asylum.

BLOMFIELD, Dc. A. G., House-Surgeon at the West Norfolk and Lynn Hospital, King's Lynn, has been elected House-Surgeon to the Devon and Exeter Hospital, vice H. Gordon Cumming, resigned.

BLOXAM, T. A., F.R.C.S.E., has been appointed Surgeon to Charing cross Hospital, vice Hird, appointed Consulting Surgeon.

BODDY, H. W., M.B., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Workhouse of the Prestwich Union, vice Buckley, resigned.

BUDD, S., M.D., F.R.C.P.L., has been appointed Consulting Physician to the Devon and Exeter Hospital.

CHEESBROUGH, H. A., M.D., has been appointed Honorary Consulting Physician to the Blackburn and East Lancashire Infirmary, on resigning as Honorary Physician.

CLARK, S., M.D., C.M., has been appointed Certifying Factory Surgeon for the District of Cullen.

CLARKE, W. B., F.R.C.S., has been elected Assistant-Surgeon [not Surgeon, as announced last week] to the West London Hospital.

COX, F. A., M.R.C.S.E., has been appointed Assistant Medical Officer and Chloroformist to the Hospital for Women and Children, Vincent-square.

DAVY, H., M.B., M.R.C.P.L., has been appointed Physician to the Devon and Exeter Hospital, vice Dr. Budd, resigned.

FISHER, T. J., M.D., M.Ch., has been appointed Medical Officer for the Fifth District of the Hackney Union.

HEMSTED, E., M.D., M.Ch., has been appointed Surgeon to the Southampton Dispensary, vice Hobley, resigned.

HIGGINS, W. H., M.B. & C.M., M.R.C.S.E., has been appointed Medical Superintendent of the Leicestershire and Rutland Lunatic Asylum, vice J. Buck, M.R.C.S.E., deceased.

HIRD, F., F.R.C.S.E., L.R.C.P.Ed., has been appointed Consulting Surgeon to Charing-cross Hospital.

KEMPE, A. W., M.R.C.S.E., L.R.C.P.Ed., has been appointed Surgeon to the Exeter Dispensary, vice W. A. Budd, resigned.

LUBBOCK, Dr. M., has been appointed Assistant-Physician to the West London Hospital, vice Dr. J. M. Fothergill, resigned.

MOLYNEUX, J. L., M.R.C.P.Ed., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Upholland District of the Wigan Union.

MORGAN, J., F.R.C.S.E., L.R.C.P.L., L.S.A.L., has been appointed Medical Officer for the Workhouse of the Langport Union, vice Tims, resigned.

MORGAN, W., F.C.S., has been appointed Public Analyst for the Borough of Haverfordwest. £5 5s. per annum, and fees.

SETH, O., F.F.P.S.G., L.M., L.S.A.L., has been appointed Medical Officer for No. 9 District of the Brighton, Hove, and Preston Provident Dispensary, vice F. Blaker, resigned.

UPTON, A., M.R.C.S.E., L.R.C.P.L., L.S.A.L., has been appointed Medical Officer for No. 7 District of the Brighton, Hove, and Preston Provident Dispensary, vice H. C. Upton, resigned.

Births, Marriages, and Deaths.

BIRTHS.

BARCLAY.—On the 5th inst., at Grantown, the wife of W. M. Barclay M.B., C.M., Edinburgh, of a daughter.

BOND.—On the 10th inst., at Delahay-street, St. James's-park, S.W., the wife of Thomas Bond, F.R.C.S., of a son.

COCKCROFT.—On the 10th inst., at Manor Lodge, Chislehurst, Kent, the wife of T. H. Cockcroft, M.D., of a daughter.

COOPER.—On the 9th inst., at South-hill-park, Hampstead, N.W. (the residence of her father, Luke Dowell Smyth, M.D.), the wife of the late Thomas Henry Cooper, M.R.C.S.E., of a posthumous son.

SMITH.—On the 11th inst., at Richmond-hill, the wife of Dr. R. Shingleton Smith, of a daughter.

WINSLOW.—On the 3rd inst., at Hayes-park, Middlesex, the wife of Henry F. Winslow, M.D., of a daughter.

MARRIAGES.

DOBSON—DOUGLAS.—On the 14th inst., at the residence of the bride's father, Edwin Francis Horatio Dobson, M.A., C.M., Her Majesty's Bengal Army, eldest son of Francis Horatio Dobson, of Happy Hall, Rangoon, Burmah, to Emily Ann (Emmie), fourth daughter of Thomas Douglas, of Airy Hall, Aberdeen.

JONES—SMITH.—On the 16th inst., at St. George's, Hanover-square, by the Rev. Frederick Smith (father of the bride), Thomas (Young) Jones, M.R.C.S.E., L.R.C.P.Ed., to Mary Agnes Coare. China and Australian papers please copy.

MASTER—MANBY.—On the 10th inst., at the Parish Church, Morecambe, by the Rev. M. N. Kearney, M.A., Canon of Elphin Cathedral, and Rector of Strokestown, co. Roscommon (brother-in-law to the bride), George Reginald, youngest son of Alfred Master, Esq., F.R.C.S. & J.P., of Norwich, to Emily Caroline, youngest daughter of the late Rev. E. F. Manby, Rector of Morecambe.

WALKER—DESHON.—On the 9th inst., at St. Michael's, Teignmouth, Ernest Octavius, son of G. J. Walker, Esq., of Brook Hill House, Teignmouth, to Rosa Eacie Anne, fourth child of the Rev. H. C. Deshon, M.D., Rector of East Teignmouth.

DEATHS.

ALTY.—On the 8th inst., at Birkdale, Southport, Lancashire, John Daniel Alty, M.R.C.S.E., late of Demerara, aged 69.

BARTLEY.—On the 6th inst., at St. Helier's, Jersey, John Metge Bartley, M.D., Surgeon on the Retired List of the Army Medical Department, and formerly of the 1st Dragoons and 39th Regiment, in his 94th year.

BIGSBY.—On the 10th inst., at Gloucester-place, Portman-square, John J. Bigsby, M.D., F.R.S., in his 89th year.

CRESSY.—On the 14th inst., at his residence, Bedford House, Gravesend, Theodore Grant Cressy, M.R.C.S.E., L.S.A.L., youngest son of the late Edward Cressy, Architect, of South Darenth, Kent, in his 51st year.

MASON.—On the 12th ult., at his residence, The Vinery, Wellington, Herefordshire, Thomas Mason, M.R.C.S.E., &c., aged 49.

TALBOT.—On the 21st ult., at St. Ann's Bay, Jamaica, Joseph Bindley Talbot, L.R.C.P.L., M.R.C.S.E., suddenly, of heart disease, aged 29.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, Feb. 21.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

MEDICAL SOCIETY OF LONDON.—8½ P.M. Mr. Samuel Osborn will show Two Cases of Hydrocele cured by Simple Tapping and subsequent application of Pulvermacher's Suspensory Bandage.—The President, Mr. F. J. Gant, will read a Case of Epithelioma of the Tongue; organ removed by Buccal Operation; both the specimen and the patient will be shown.—Dr. Gilbart Smith will exhibit Photographs of the Mechanical Means used by Dr. Lauder, of Stockholm, for Exercising Weakened Muscles.—The President may also show Gale, the Pedestrian.—Mr. Royes Bell will show a Specimen of the Tongue Removed by Nunneley's Operation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor W. K. Parker, "On the Structure of the Skeleton in the Sauropsida."

Tuesday, Feb. 22.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Edward A. Schäfer, "On the Blood."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Spencer Wells, "On Two Hundred additional Cases, completing One Thousand Cases of Ovariotomy, with remarks on recent improvements in the operation."—Dr. George Thin, "On the Development of a Layer of Elastic Fibres in Duct Cancer of the Breast."

Wednesday, Feb. 23.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

HUNTERIAN SOCIETY.—8 P.M. Introductory Address by the President.—Mr. T. E. Adams, "On Diphtheritic Ophthalmia."—Mr. G. T. B. Stevens, "On a Case of Erysipelas of the Scrotum and Penis."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor W. K. Parker, "On the Structure of the Skeleton in the Sauropsida."

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND SCIENCES.—Mr. W. H. Preece, "On Recent Advances in Electric Lighting."

Thursday, Feb. 24.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Pauer, "On Drawing-room Music."

Friday, Feb. 25.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1¼ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—8 P.M. Dr. J. S. Burdon Sanderson, "On Excitability in Plants and Animals."

CLINICAL SOCIETY OF LONDON.—8½ P.M. Dr. Hilton Fagge, "On a Case of Paralysis due to Partial Disease of the Nuclei of the Motor Roots of the Fifth Nerves."—Mr. Teale (Scarborough), "On a Case of Quiescent Scirrhus."—Dr. Crocker, "On Cases of Erythema Iris."—Dr. F. Taylor, "On Cases of Pemphigus and Herpes Iris."

QUEKETT MICROSCOPICAL CLUB.—8 P.M. Ordinary Meeting.

Saturday, Feb. 26.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Mr. R. S. Poole, "On Ancient Egypt."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

REGISTRARS AND UNCERTIFIED DEATHS.

WITH reference to cases in which the Registrar of Births and Deaths is in doubt whether a medical practitioner be registered or not, a correspondent asks whether a registrar cannot demand of the practitioner to see his certificate of registration. We are glad to say that neither the law nor the regulations issued to registrars by the Registrar-General give any such right or instruction to registrars. A registrar is, however, precluded from recognising as legal the certificates of, or from supplying forms of certificates to, any unregistered practitioner. It is therefore necessary sometimes to make a personal or written inquiry of a practitioner as to whether he is registered, but registrars are instructed "ordinarily to accept the statement of a medical practitioner that he is duly registered, but that in cases of doubt the circumstances must be reported to the Registrar-General for instructions." If any registered practitioner becomes aware that the written statements of an unregistered practitioner are being accepted as legal certificates, it is clearly his duty, both to the profession and to the public, to report the case to the Registrar-General. In the case of a deceased person, however, who has not been attended by a registered medical practitioner in his last illness, the registrar is acting strictly in accordance with his instructions, to accept the statement of the unregistered or unqualified practitioner for what it is worth, and to enter the cause of death in his death register as uncertified. In the present state of the law no other course is open to him, since the registrar is liable to a penalty if he does not register the death, and there is no possibility in such cases of getting a legal certificate, unless the local coroner should see fit to hold an inquest.

Dr. William Price.—We do not recommend, specially, physicians or surgeons for particular diseases.

Rickmansworth will not, we fear, readily procure what he desires except by specially advertising for it.

Mr. Geo. R. Barnes.—Application might be made to one of the nursing homes.

SMALL-POX AND VACCINATION.

Inquirer.—There is but one known protective against small-pox—vaccination. If a person has been efficiently vaccinated in childhood and efficiently revaccinated at or after puberty, he is as safe against the contagion of small-pox as he can possibly be rendered. Efficient vaccination and revaccination can be obtained without charge at the public vaccination stations. No known drug exercises the least degree of protective influence. A properly vaccinated nurse in a small-pox hospital who has contracted small-pox is, we believe, unknown. Our correspondent should write to the secretary of the Local Government Board and ask for a copy of the Board's Memorandum on Revaccination.

CASE OF SPINA BIFIDA AND TALIPES.

To the Editor of THE LANCET.

SIR,—On the 23rd October, 1880, I was called to attend Mrs. R——, Pimlico-road, in her fifth confinement (natural labour), but the child (male) malformed, with spina bifida and talipes. The tumour is the size of a small orange, reaching from the last dorsal to the fourth lumbar vertebra; it is slightly transparent, and discharges a little straw-coloured fluid. A gutta-percha cone is placed over the tumour to protect it. The child grows, and he is larger than most children for his age. In THE LANCET, 1871, you published a similar case of mine. The child died at four months, the tumour sloughing, and convulsions set in.

I am, Sir, yours, &c.,

Jan. 24th, 1881. FREDERICK T. COATES, M.R.C.S. Eng.

CURIOUS DISPUTE BETWEEN A MEDICAL MAN AND HIS ASSISTANT.

IN the Preston County Court a few days ago a somewhat remarkable claim was lately made by Mr. Charles Allen, an unqualified assistant, from Dr. Bowen, of Ribblesdale-place, Preston. (The case is fully reported in the *Preston Herald.*) Mr. Allen had been engaged in November, 1879, as assistant for twelve months. This period passed over harmoniously enough, and, after some conversation, Mr. Allen understood that his principal was satisfied, and renewed the engagement for a similar time. But in December some unpleasantness arose in consequence of the assistant indulging in a fire in his bedroom, which filled the house with smoke. Defendant thereafter told plaintiff to take a month's notice. The plaintiff, adhering to the view that he was engaged for a year, refused to go, and had to be removed by four bailiffs and two policemen. He then took action in the county court to recover the sum of £50 as damages for a breach of contract. It was not maintained that there was any written contract. The judge, in a lengthy summing up, dwelt on the undesirability of verbal contracts, observing that much litigation would be avoided if contracts were always made in writing. He gave judgment for the defendant, but declined to allow the costs of witnesses.

ENURESIS.

To the Editor of THE LANCET.

SIR,—I assume that your correspondent has looked for and treated any peripheral source of irritation—e.g., any morbid condition of the urine, collections of smegma under a long prepuce, phimosis, ascarides in the rectum, and even examined for stone should he have thought the presence of one possible. None of these conditions being present, I recommend him to try belladonna in increasing doses, and to push the remedy perseveringly for two or three weeks if necessary. In those cases associated with dreams I have found bromide of potassium sometimes useful. I should restrict the patient to water as a beverage, order him to sleep on a mattress with the pelvis raised so as to direct the urine towards the fundus of the bladder, give a purgative once or twice a week, and make him urinate at regular intervals.

One meets with hereditary cases and cases among highly neurotic families that derive little benefit from any treatment, but who overcome the weakness as age advances. I believe this incontinence of urine is often associated with masturbation.

I am, Sir, yours, &c.,

Tufnell-park, N., Feb. 6th, 1881. HAYDON WHITE.

To the Editor of THE LANCET.

SIR,—In reply to the query put by "Ex Fide Fortis" in your last impression, allow me to mention the successful treatment that I have adopted with several young children—boys and girls—who used to habitually wet their beds. It is very simple. Withhold all flesh meat as food, and give good fresh cow's milk freely—e.g., three pints in the twenty-four hours for a child from three to four years of age, and this besides the regular meals. Breakfast consists of stale whole-meal bread and milk; supper the same; dinner (at 1 P.M. or 2 P.M.), potatoes and gravy, with half a pint of milk, and half a pint of milk to be given midway between breakfast and dinner. In troublesome cases a hot bath should be given morning and night, and in all cases the bed should be well warmed before the child is placed in it. Flannel should be worn next to the skin day and night, and the child should be invited to micturate at stated times, and should be taught "to call" the nurse not less frequently than every two or three hours. In only one case out of ten during the past few months have I been compelled to prescribe any medicinal remedy.

I am, Sir, yours, &c.,

BERNARD O'CONNOR, M.D., M.R.C.P. (Lond.).

Brook-street, W., Feb. 9th, 1881.

To the Editor of THE LANCET.

SIR,—In reply to the request of your correspondent "Ex Fide Fortis," I beg to state, in the treatment of the above complaint, I have usually found the liq. ferri perchloridi, combined with tinct. nucis vomicæ, in doses of twenty minims each or less, according to age, invariably beneficial. I think he will do well to give this remedy a trial.

I am, Sir, yours faithfully,

St. Faith's, Norwich, Feb. 7th, 1881. J. HAWKES, M.D.

To the Editor of THE LANCET.

SIR,—In answer to "Ex Fide Fortis," I may state that during the past two years I have had several cases of this unfortunate complaint as well as an old fisherman (nearly eighty), who could not sleep for the urgency of frequent micturition, all of which were cured by the use of that old-fashioned remedy, tinct. mur. ferri (alias tr. sesquichlor. fer.) in small doses, well diluted with water. In the last-mentioned case it was combined with tinct. fol. hyoscyam.

I am, Sir, yours most respectfully,

J. C. REID, M.D., Medical Officer of Health.

Newbiggin-by-Sea, Feb. 9th, 1881.

⁂ Many other letters on this subject have been received, in which the writers recommend remedies similar to those mentioned above.—ED. L.

Sulphur in Wool and in Hair.

In reference to a paragraph in our issue of Feb. 5th on this subject, Mr. J. Lawrence-Hamilton, of Gloucester-terrace, Hyde-park, writes:—"According to the analyses of Frémy and Pelouze, hair contains about 5 per cent. of sulphur, and wool roughly about 2·3 per cent. of sulphur, which quantities of sulphur are returned again from the wool to the soil, after the wool has been worn out in the form of clothes, in the shape of the so-called shoddy-manure, whilst the hair derived from the head of human beings finds its way through the dust-bin and dust-cart to the manure-heap, and thence once more to the earth. Thus no appreciable sulphur waste can occur. In other ways, as by the use of artificial superphosphate manures, enormous quantities of sulphate of lime are supplied to the soil, and in far larger proportions than are removed by the growth of wool and hair. Further, the value of wool and hair as manures does not depend alone upon the contained sulphur, but indeed almost entirely to the contained nitrogen, which in wool and hair manures amounts usually to upwards of 17 per cent."

Medical Student can have no difficulty in obtaining all the information he requires on the subject named. We cannot give any special directions, nor can we conceive that, under the circumstances, they are needed.

G. A.—We regret that we have been unable to trace the communication.

SALICYLATE OF QUININE IN NEURALGIA.

To the Editor of The Lancet.

Sir,—In March and April last year I had the honour to report to you the good results I had obtained from the use of salicylate of quinine in rheumatic and gouty affections, particularly in subacute and chronic cases. These results have been maintained to even a greater extent than I could have anticipated. Many patients continue to have recourse to it when necessary, and recommend it to their friends far and wide.

I said then that I was not aware what the result might be in acute cases, as I had not had any opportunity of so testing it. Since that time, however, I have been favoured with opportunities such as I desired, and I have now to report that salicylate of quinine has not in my hands proved successful in truly acute cases.

But my special purpose in this communication is to make a note of the value of salicylate of quinine in neuralgia. Many, indeed, are the remedies which have been employed in the treatment of the array of these, so to say, non-pathological disorders, which are conveniently enough grouped and set forth under this term. Gelseminum in doses of twenty to thirty minims has a splendid effect, and there are others; but I beg to note here particularly the masterly action of salicylate of quinine in neuralgia in doses of six grains.

I am, Sir, your obedient servant,
Feb. 14th, 1881. Archibald Hewan.

Education of Blind and Deaf-Mute Children.

A Bill for the Better Education of Blind and Deaf-Mute Children, prepared and brought into the House of Commons by Mr. Woodall, Mr. Benjamin Willyams, and Mr. Montague Scott, has just been printed. It provides that, on the application of the parents, boards of guardians may send a blind or deaf-mute child to school, who may be retained there till the age of eighteen years. Provision is made for children being received into schools established in connexion with the religion to which their parents may happen to belong. To the Local Government Board is reserved the power, under certain circumstances, to order the removal of such afflicted child from school.

Sanitary.—The question put is a legal one, and should be addressed to a journal dealing with legal questions—e.g., the *Local Government Chronicle.*

Enquirer.—Too late for this week.

Medical Student.—The extension proposed was tried in the army for four years, and the drawbacks were found greatly to exceed any benefit from it. We cannot, therefore, recommend it.

POISONING BY HYDROCHLORIC ACID.

To the Editor of The Lancet.

Sir,—Perhaps you may think the following notes worthy of a place in your columns:—On September 20th, 1879, I was called to see a woman who had taken three ounces or more of hydrochloric acid, having disagreed with her husband. I was called in three or four hours after she had taken it. I at once gave her magnesia, chalk, and olive oil. She had vomited a short time before my arrival a dark-brownish fluid, and continued to do so for some hours. Milk was given with soda-water and opium, and turpentine applied over the abdomen; also calomel and opium pill was prescribed, to check the inflammation. Gastritis and enteritis followed three days after taking the acid. A great deal of pain for some time remained in the stomach, which was relieved with bismuth and opium, also copper and opium. The patient quite recovered after six weeks.

I am, Sir, yours, &c.,
Jan. 24th, 1881. Frederick T. Coates, M.R.C.S.E.

The General Medical Council.

The remarks of Dr. Fergus at the special meeting of the Council last week were, by an error of the reporter, wrongly attributed to Dr. Scott Orr.

DESQUAMATION AFTER SCARLET FEVER.

To the Editor of The Lancet.

Sir,—The questions asked under this heading by a correspondent in The Lancet of Feb. 12th are of very considerable practical importance. I do not write to offer an opinion upon the particular subject matter of these letters, but I ought not, I think, to withhold on such a fitting opportunity whatever information I may be able to communicate through your columns upon the several strictly medical points involved.

My experience of scarlatina is pretty wide, and, so far as this part of its symptomology is concerned, amounts to this:—1. That in slight attacks of the disorder desquamation of the cuticle is often delayed, sometimes remarkably so. In one instance within my own knowledge, that of a young lady fifteen years of age, the desquamation was not perceived, although daily sought for, until the fifth week from the beginning of her illness. Very fortunately, the patient had meanwhile been strictly isolated from the other members of the family.

2. That in the treatment of scarlatina it is unwise to make any distinction between slight and severe attacks of the disorder. Altogether apart from the question of infection, there is to the patient suffering from a mild attack positive risk to life from exposure within at least the first five weeks, and some of the worst cases of albuminuria and dropsy I have seen were of children suffering from attacks of the fever of such mildness as to hardly deserve the name.

3. That in the matter of sanitary precautions against the dissemination of infection, it is utterly wrong to permit any scarlatinal patient whatever to mingle with the healthy until the expiration of eight weeks from the beginning of the illness, and, in those cases where the desquamation of the cuticle is of late appearance, until this process is completed, and for a fortnight afterwards.

I cannot now enter into details, but if I may be permitted I would refer to my pamphlet on the subject (Facts about Fevers, second edition. Maclachlan and Co., Edinburgh; Simpkin and Marshall, London) for evidence in support of these conclusions. I am glad to express my approbation of the step your correspondent has taken in referring this matter to the columns of a medical journal. Much more harm than good is the almost inevitable result of an appeal to the readers of a general newspaper and the public, even the so-called educated and reading public—ever too ready to seize upon any teaching which errs on the side of laxity, and enables it to dispense for its selfish ends with such proper but tedious sanitary precautions.

Your well-merited censure upon the mischievous nonsense which was lately attempted to be promulgated in the columns of a leading contemporary upon this same subject of scarlatinal infection must have been gratifying to any experienced member of the profession.

Kendal, Feb. 12th, 1881. David Page, M.D.

To the Editor of The Lancet.

Sir,—I beg to send you the following facts of the case alluded to in the correspondence under the above heading, published in your last issue:—

On the 16th December, two days before the boys were leaving for the Christmas vacation, one of their number (who had been visiting elsewhere a few days previously) was found to be suffering from scarlatina. He was at once removed to the infirmary, and I gave instructions that all the others should be closely watched and examined previous to allowing them to return to their homes.

On the following night I was sent for to see the boy referred to in the letter of "Enquirer." I examined him, and found his pulse, temperature, and tongue normal, but fancied I detected (as the matron had previously done) a slight suspicious eruption appearing about the shoulders; the fauces, too, looked a little inflamed, though the lad hardly admitted that he felt any soreness of the throat.

Under all the circumstances, I deemed it prudent to have him isolated, and he was consequently removed to the infirmary. From that time the symptoms were never more marked; on the contrary, on the following day the boy was as well as ever he was. However, in order to avoid all risk, I had him kept to the infirmary for three weeks, and examined him myself frequently to the last for any desquamation of cuticle, of which at no time were there any signs whatever. During the last ten days he had, by my direction, many baths and anointings; and, after complete purification, he left here in entirely fresh clothing (that which he had previously worn being retained to be disinfected) to rejoin his friends.

I believe his father expressed dissatisfaction at his being sent from here so soon, thinking it unsafe but, seeing that the boy has enjoyed perfect health, and that no other persons have suffered from his presence among them, I fail to see what charge I am called upon to answer. Indeed, I feel confident that you, Sir, as representing the opinion of the profession, will consider that in the action taken by me I showed a due regard for the health of the boy and the safety of the public.

As for the desquamation (?) which is said to have been discovered six weeks after he came under my care, it is more likely due to eczema (from which I am given to understand the lad has previously suffered) than the result of scarlatina, which my experience goes to prove immediately follows the attack.

I am, Sir, yours faithfully,
Feb. 14th, 1881. The Medical Attendant of the College.

VACCINATION BY UNQUALIFIED PRACTITIONERS.

A CORRESPONDENT asks whether in case of an unqualified practitioner vaccinating and filling up certificates of successful vaccination, the Registrar-General would interfere. The Registrar-General has no authority for securing the efficient operation of the clauses of the Compulsory Vaccination Acts. Primarily the vaccination officer, who is not always or even often a registrar, would be at fault for accepting a certificate of successful vaccination from any but a registered medical practitioner; and any complaint against a vaccination officer concerning the performance of his duties should be addressed to the Local Government Board. Registrars have certain duties to perform in connexion with the Vaccination Acts, but unless they happen to be also vaccination officers they have nothing to do with the registration of successful vaccinations, and in that capacity they are under the control of the Local Government Board, which is the central authority in vaccination matters.

PAYMENT OF MEDICAL OFFICERS TO ODDFELLOWS' SOCIETIES.

To the Editor of THE LANCET.

SIR,—In reference to the above, I think your correspondent, Mr. Hart, well paid according to the fees received in my district. I have an Oddfellows, Foresters, and Shepherds society, each of which, when I obtained them, paid me the handsome sum of 2*s.* 6*d.* per head per annum, which was afterwards, on my application, raised to 3*s.*, but, owing to want of funds, the Oddfellows have reduced it to 2*s.* 6*d.*, at the same time the following expression being used in the lodge-room:—"There are other doctors in the district who will be glad to take it at that," and to which I add, "Yes, and canvas the members to obtain it." But Mr. Hart's words are true, "the payment is preposterously small, but as there are plenty of medical men ready and willing to accept this small sum, it will have to remain until there is some unity amongst us and a general demand for higher fees." Of course a small amount of private practice does accrue from attendance upon the members' families, but I find in a great many cases that they do not send for their club doctor.

I am, Sir, yours faithfully,

Feb. 14th, 1881. ANOTHER CLUB DOCTOR.

To the Editor of THE LANCET.

SIR,—The answers to your correspondent, Mr. F. D. Lys' letter, on the above subject, in THE LANCET of January 22nd, give such a very wrong impression that I feel justified in asking space for this letter.

Several years ago a meeting was held at Melton Mowbray, at which the medical men practising in that neighbourhood discussed the question of club pay, and unanimously decided to take no Oddfellows at less than 5*s.* per member per annum. It was also decided to stop the practice of examining candidates for admission into these clubs gratis, and 2*s.* 6*d.* is now charged for the examination. It was further decided that tradesmen, innkeepers, and others who were believed to be able to pay the usual fees for medical attendance should not be received on the surgeon's club-list; and it was further understood—and, as far as I know, honourably carried out—that any person who had been refused admission by one man, because able to pay the usual private patients' fees, should not be accepted on the club-list of another. I think the question of charging for attendance in cases caused by intemperance, &c., opens too wide a field for dispute; I prefer exercising the right of crossing off the club-list any such individual.

I agree with Mr. Hart that unity amongst us is very desirable, but the courage which prompts and decides an independent demand for higher fees, where those received are acknowledged to be "preposterously small," is much more desirable.

I am, Sir, yours respectfully,

Somerby Oakham, Feb. 7th, 1881. JOHN JACKSON.

ABSTRACT OF A

Clinical Lecture

ON THE

TREATMENT OF SOME FORMS OF EPILEPSY.

Delivered at the Hospital for Epilepsy and Paralysis,

By J. S. RAMSKILL, M.D. Lond.,

SENIOR PHYSICIAN TO THE HOSPITAL, CONSULTING PHYSICIAN TO THE LONDON HOSPITAL.

Gentlemen,—The boy I show you (L——) says he is eight years of age, and that he has been ill eight months. He looks his age, and is fairly intellectual. He had been at school for five years before the accession of the fits. The shape of his head is good, and there is no particular vaulting of the roof of the mouth. I always examine the mouth both with a view of ascertaining the height of the roof and the state of the teeth, both as regards caries and overcrowding. About the age of puberty the latter condition is not a very rare cause of epilepsy. And it is always well to exclude every source of irritation arising from that most reflex nerve of the body, the trigeminus.

We have no neurotic family history, and no account of any previous illness to note. Examination of the heart and lungs reveals nothing, neither does the ophthalmoscope. The abdomen seems full, some gurgling sounds are heard on palpation, and it is more doughy than natural; but on account of a certain amount of superficial fat, the state of the colon and viscera can hardly be made out. Now, about a month before the commencement of the fits, the boy complained of a bad cramp in the left wrist and upper half of the hand. It remained only a few seconds, but recurred at different intervals; sometimes twice or three times a day, and next day only once. About the end of a month he was knocked down by a blow on the left side of the head. He did not lose consciousness, nor was he sick, neither had he subsequent headache.

Next morning he had a fit, and several during the next fourteen days; then he was free for a month. They then returned, but only by night; but during the following month they came both by night and day. We learn from the parents that the character of the fits is as follows:—He first has the cramp in the left hand and wrist, screams, and also, sometimes, bites his tongue; is universally convulsed, but most so on the left side. The fits last only a few seconds. He occasionally has one in the day, but usually eight or ten every night. It is observed that if he falls asleep during the day he has a fit. There are no sequelæ of note to the attacks.

Such is the aspect of the patient and the history of the case. The first point to decide is this: Is the patient epileptic? and, if so, is the disease idiopathic and primary, or is it secondary or sympathetic? It would be waste of time to argue the first question. The case is clearly epileptic; but it is quite a question as to whether it be idiopathic or not. Modern science would at once say it is centric, and the particular part of the brain most involved was the right ascending frontal convolution, an explosion from which spreads upwards, downwards, and backwards, involving an area which might be mapped out by the presence of convulsion or spasm in the muscles engaged. The aura does not consist of an irritation going to the brain, although a ligature above its seat may stop the fit. You all know aura may exist with coarse centric disease, and a ligature may still stop the accession of the fits. This, I say, is the received opinion; but I am not sure of its universal truth, especially with regard to unfelt aura, which we must suppose to exist. An unfelt aura seems a contradiction in terms; but it is not so, for, as far as I can make out, in the case of a patient who one day has a fit with an aura, and next day another of exactly the same extent and character without any, there must have been a similar, or the same, cause in both.

I think, perhaps, the explanation lies here, that the spread of the discharge was too quick, that the patient had not time to perceive the aura before the attack became general, or before consciousness was lost. But we find on examination the boy has often the aura without a fit. Then I look on his aura as a fit—a minor and localised one. A greater question to my mind is this, Are not most epilepsies eccentric rather than idiopathic and centric at first? Does the existence of an aura really settle everything? Neither physiology nor pathology helps us, but I think practice can. If you prevent both aura and fit, by slight treatment, which cannot reasonably be presumed to have any influence on the cerebro-spinal centres, it is a fair supposition that the cause is not centric, but originates within the sphere of action of your treatment. But I do agree to this opinion, that eccentric soon passes into centric idiopathic epilepsy, or perhaps, that you may, after one has generated the other, have both forms of disease in the same subject. Be this so or not I am inclined, and I dare say you are, to say with the celebrated Trousseau, "Good heavens, gentlemen, a little less science—a little more art." The question then is what line of treatment shall we pursue. This is the programme we adopted.

(*a*) To see if we could find any source of irritation in the abdomen, "for of all the regions of the body there are none which reflect more strongly on the brain than the intestines and visceral organs."

(*b*) To give what remedies we know are able to allay the reflex excitability and force of the cerebro-spinal centres.

With the first object in view, vermifuge aperients, santonine and castor-oil, is the usual combination for children, to be given sufficiently long to make sure of the result.

In our case the result was *nil*. Had a worm been expelled the fits might have vanished; but this is not the rule, unless your treatment has commenced very early in the case after the first attacks. The lumbricus may be dislodged, but the central excito-motor region has taken on morbid action, and the epilepsy remains. Still, in these cases, I always think there is most hope, and most room for treatment; for if the irritation of a lumbricus could by a certain route in the nervous system produce a morbid result on the centre, some remedy acting through the same route may lessen, deaden, and finally stop that morbid process in the same centre.

Let us continue our examination of the abdomen. I want to know the condition of the colon. We have found the abdomen full—that is, tumid, bigger than it should be, but without chloroform we cannot make out anything beyond gurgling.

By the light, then, of experience we make the assertion, that there is probable defect of the colon, as to secretion, spasm, contraction, and alternate dilatation of its calibre. In a post-mortem of an epileptic by Vanderkolk he says: "We found in the abdominal cavity the colon and sigmoid flexure very much dilated and lengthened, the latter ascending to the transverse colon. Above and beneath the sigmoid flexure were many constrictions, which higher up alternated with dilatations; the cæcum, too, was very dilated." This is a severe case; but one cannot help observing in the records of post-mortems the frequent occurrence of a strictured and dilated colon.

What cases of mental depression, of melancholia, have we not all seen associated with loaded, and probably sacculated, colon! In one series we seem to get an irritant; in the other an inhibitory action on the nerve centres. I recollect an old practitioner saying (before the advent of bromide) that a daily morning dose of beaume de vie was of more service in epilepsy than all the medicines in the Pharmacopœia.

To recur to our patient, we kept him in the hospital ten days without treatment, beyond the prelude of aperients, to see his exact condition as to the kind, number, and duration of the fits.

On Oct. 13th he had 5 fits; 14th, 7 fits; 15th, 15 fits; 16th, 13 fits, and one in the afternoon, when he had fallen asleep; 17th, 9 fits; 18th, 6 fits; 19th, 7 fits; 20th, 15 fits; 21st, 9 fits; 22nd, 15 fits. The fits turned out as described. On Oct. 23rd we ordered thirteen grains of bromide of potassium, three grains of iodide of potassium, and eight grains of carbonate of ammonia, three times daily, with this result:—Oct. 24th, 9 fits; 25th, 7 fits; 26th, 11 fits; 27th, 9 fits; 28th, 13 fits; 29th, 9 fits; 30th, 9 fits; 31st, 10 fits. The same rate continued until Nov. 4th, when we added more ammonia in the shape of ammoniated spirit. The rate began to diminish, as for the consecutive days we got 7, 6, 6, 7, 2, 8, 6, 5, 6, 5—plus one in the day—then 5, 6, 9, 5, and about the same rate until Nov. 27th. On that day a mixture of equal parts of chloral, camphor, and vaseline was ordered, a portion equal to a small teaspoonful was to be rubbed into the scalp every night. The mixture of bromide, iodide, and ammonia, to be continued, and a pill containing equal parts of aloes, valerianate of zinc, and extract of conium, given every night.

The result of this treatment was, that we had no recurrence of fits of any kind for more than five weeks. Then we had one fit each night for three nights, and I confess that I was glad to see them return. Vanderkolk quotes some cases showing the danger to life which may arise from the prolonged freedom from fits. And, as a general rule, it may be said that in chronic epilepsy the longer you manage by treatment to prolong the interval between the attacks the more severe the following fit will be. Death occurs from asphyxia or from congestion of lungs and coma. It is astonishing that apoplexy is not frequent, but to me it is simply unknown as a result of the most violent and prolonged attacks.

I have had experience only of three fatal results; all occurred after a so-called cure had been made; all in the night, and the patients were found dead in the morning. What I wish you to remember is that after a prolonged interval of freedom you must apply some counter-irritant, such as a seton, issue, or leeches, to prevent or to break a too violent explosion.

To return to our case, To what is the improvement due? What is the rationale of the action of the means employed? Perhaps we should do best to see these points illustrated in another case.

ON A NEW METHOD OF SUPPLEMENTARY ALIMENTATION.

By A. ERNEST SANSOM, M.D. LOND., F.R.C.P.

(Concluded from p. 289.)

THERE can, I think, be no doubt that the administration of artificially digested food per rectum in the manner previously described is a distinct therapeutic gain, and that when we advise nutritive enemata of the kind that we have hitherto employed, we ought to direct that the pancreatic ferment should be added thereto. But I have now to draw attention to a still more recent method of fulfilling the object which we have in view.

It occurred to my old and valued friend, Dr. Andrew H. Smith of New York, that the artificially dissolved juices of flesh which we have hitherto employed might very probably be inferior to the perfectly fluid and wholly absorbable flesh which nature has prepared for us. In what other substance could we be so certain of finding all the elements of the blood as in the blood itself? Dr. Smith pursued his inquiries, and found that when *blood* was administered per rectum both corpuscles and serum were absorbed. Three or four ounces of defibrinated blood having been injected into the rectum at night, no trace was found in the evacuations of the following morning. An interesting observation was made showing how absorption can take place from a surface much greater than that of the limited portion of the rectum in which the injection is first retained. A man under Dr. Smith's care in the St. Luke's Hospital of New York received every evening an injection of 120 grammes of blood. He was in the last stage of pulmonary phthisis, and died suddenly eight or nine hours after the last enema had been given. At the autopsy it was found that the large intestine was very evenly lined with a coating of thickened blood for a distance of nearly three feet. It would seem, therefore, that in the case of nutritive solutions administered by the rectum there is a retrograde peristalsis, whereby the material is spread over a considerable extent of the absorbing surface of the bowel.

Now, as to the *mode of employment of blood enemata.* Ox blood is usually employed, but sheep's blood may be used. It is necessary that it be defibrinated the moment it is drawn. Butchers understand this process, and will supply what is called "whipped" or "stirred" blood. It is, of course, requisite that the blood be fresh—that it be not kept more than a single day.[1] In urgent cases, where there is no stomach digestion, two or three ounces of blood may be injected into the rectum every two or three hours; the fluid may be warmed by placing the containing vessel in hot water, but it is often borne equally well when cold. For chronic cases, in which it supplements stomach alimentation, it is administered in quantities of from two to six ounces once or twice a day. In some cases its use tends to promote constipation; in a very small percentage the opposite condition of irritability.

Blood enemata thus administered present many practical advantages. The supply is easily obtained; the cost is very small—a really important point amongst the poor when a long-continued course of nutrition per rectum is ordered, one which hitherto has entailed a large outlay for the juice of meat and adjuncts—and the evidence of success is, as I shall presently show, considerable. On the other hand, in procuring the supply of fresh blood there may be some difficulties; especially is this the case when it is wanted in a great hurry, when, for example, the administration of blood per rectum is suggested in a case where direct transfusion might heretofore have been adopted. This difficulty is now overcome because the blood is prepared, concentrated, and preserved in tins, and thus is ready for immediate use. The preparation of this sanguis bovinus exsiccatus is conducted under the direct supervision of Dr. J. J. Craven, inventor of the great ship refrigerators for preserving meat during ocean voyages. The blood is taken from selected animals, and these are bled to death; this, it is said, being the only method of obtaining the blood duly arterialised. The blood is carefully dried at a temperature which never exceeds 110° F. Thus prepared desiccated blood is soluble in water at temperatures below 160° F., and contains all the elements of healthy blood, save water and fibrin. To prepare the injection the concentrated blood is dropped into the warm fluid which is to constitute the injection—a fluid drachm of the concentrated representing a fluid ounce of the ordinary blood.

Now, lastly, I have to consider the evidence of the success of this plan of treatment, and this will involve some indications as to the cases in which it may be employed.

1. Cases in which it has alone sufficed to support life. These, of course, afford the most crucial test of its value, but they are of necessity rare. Dr. Smith has narrated a case of gastric ulcer kept long upon milk diet; finally everything was rejected by the stomach, and for a fortnight the patient was nourished *entirely* by enemata of defibrinated blood. Yet she lapsed into a typhoid condition, and became almost moribund. It was then found that brandy was mixed with the blood at the time of injection; it was considered that the brandy coagulating the albumen militated against absorption. So the blood was administered alone, an occasional teaspoonful of brandy and milk being given by the mouth. Then ensued an astonishing improvement, and the patient made a perfect recovery. Another case is recorded by Dr. Hanks, in which after profuse uterine hæmorrhage all food was rejected by the stomach. Here four to six ounces of fluid blood were injected per rectum three times a day. The patient improved steadily during the use of the injection, till the stomach became tolerant. Dr. F. W. Brown[2] has recorded a case of diphtheritic paralysis in a child of two years in whom starvation was imminent. The desiccated ox blood administered per rectum appeared to cause immediate reaction, and its use was followed by complete recovery. These instances, I consider, are enough to establish a strong *primâ facie* case in regard to the nutritive value of blood enemata.

2. Cases in which it has supplemented nutrition through the stomach. The evidence by which this can be proved is—(*a*) amelioration of symptoms; (*b*) gain of weight.

Perhaps as the least complex condition in which these enemata have been adopted as a method of treatment we may consider dyspepsia. One of Dr. Smith's cases was that of a young man (aged twenty-two), with extreme irritability of stomach. Even the smallest quantity of solid food induced vomiting. "No medicine was ordered, but he was directed to take a teacupful of blood by the rectum twice a day, and to apply a belladonna plaster over the stomach. The epigastric pain and the vomiting ceased within two or three days, and solid food was taken without inconvenience. In seventeen days he gained in weight 11½ lb." In another case (reported by Dr. Geo. Bayles), a patient was nourished for nearly nine weeks with blood injections, only a little claret-and-water, toast-water, or tea with milk being taken by the mouth. Under this treatment there was gain in weight and the patient recovered. In the following case under my own care at the North-Eastern Hospital for Children, the evidence of the direct value of the blood enemata may appear more doubtful, but yet my own belief was that the method was one whereby a fatal result was averted, and difficulties tided over till stomach digestion was resumed. The case was one of peculiarly difficult diagnosis. A boy of eleven complained of excruciating pain after all food in so far that he voluntarily starved himself. Cerebral troubles and many forms of abdominal disease were simulated, but one could not arrive at a precise diagnosis. Under observation in the hospital, however, the following phenomena occurred :—Retention of urine, appearance of some blood in the urine, afterwards a little pus and crystals of oxalate of lime; with this tenderness and a little swelling doubtfully felt deep in the left iliac region. I think it most probable that the pain was produced by the irritation of the left ureter by oxalic calculi. However, the boy lapsed into a most critical state; he took no solid food and very little liquid; and then I ordered blood enemata (four ounces), at first once, afterwards twice a day. At this time he took a very little milk, and occasionally a dry biscuit, but nothing else. After continuing nearly four months in a critical state I got him to take, by the stomach, first milk, beef-tea, and cocoa, then cod-liver oil, then boluses made of bread and raw meat, and lastly boluses made of cooked meat (he could not touch meat in the usual way), and then, strange to say, he took a liking to uncooked Nestle's food. His weight during his illness fell from 3 st. 6 lb. to 2 st. 13 lb., but when he began to mend it gradually rose to 3 st. 12 lb., when he was discharged. During the period of blood enemata it was maintained for two months between 3 st. 3 lb. and 3 st. 4 lb., but the gain of weight was distinctly traceable to the recommencement of stomach digestion. In another case under my care at the London hospital, I consider that the evidence was less equivocal. This case was one of greatly dilated stomach, intense anæmia with purpura on the body, attended with severe pain and vomiting; there had been history of scorbutic affection. Half a pint of defibrinated ox blood was administered night and morning. After three days the patient felt much better, and made a very good recovery.

---

[1] I have just learned by a letter from Dr. A. H. Smith that the addition of a grain or a grain and a half of chloral hydrate to each ounce of the blood serves to avert decomposition, and to prevent any offensive odour in the dejection.

[2] American Therapeutic Gazette, p. 271, Sept. 1880.

In anæmia the plan of treatment would seem to be especially indicated, and Dr. Smith has reported cases which seem to establish its value. Instances are also given in which it has greatly relieved inveterate neuralgia, one case gaining 5 lb., and another about 3 lb., in six weeks. In cases of pulmonary phthisis a decided improvement was recorded in one half the cases reported.

It will be understood that my object in bringing this subject forward is to establish a *primâ facie* case. Enough has, I think, been adduced to point the desirability of further observations. The opportunities of making such observations must occur in the course of the practice of us all.

Devonshire-street, Portland-place, W.

CASE OF STRANGULATED CONGENITAL UMBILICAL HERNIA.

BY FREDERICK TREVES, F.R.C.S.,
ASSISTANT SURGEON TO, AND SENIOR DEMONSTRATOR OF ANATOMY AT, THE LONDON HOSPITAL; ERASMUS WILSON PROFESSOR OF PATHOLOGY AT THE ROYAL COLLEGE OF SURGEONS.

I VENTURE to draw attention to the following case of hernia, not only on account of the rareness of this form of rupture, but on account mainly of its important clinical bearings, the necessity for its early recognition, its remarkable tendency to cure even when seriously complicated by strangulation or rupture of its sac and coverings, and the success attending certain operative procedures for its relief.

An infant was brought to me at the London Hospital in August last with the statement that its bowels had never been opened, and that something was amiss with the umbilical cord. I saw the child on a certain Tuesday afternoon and it had been born in the early morning of the preceding day. The child, a male, was small and wizen, and the umbilical cord at its point of connexion with the abdomen presented an oval and uniform swelling about the size of a bantam's egg. This swelling was in the cord itself, and that structure at its union with the abdominal parietes was but little larger than normal. It appeared, indeed, as if the funis immediately beyond its attachment had undergone a sudden oval enlargement and was normal both on the distal and proximal side of that swelling. The coverings of this swelling and of the cord beyond appeared to be in every respect normal. Nothing had passed the child's bowels since its birth, and a little milk-and-water administered occasionally in a spoon had been in every instance rejected. The infant kept its legs drawn up, the belly was tense and a little distended, and the child appeared to have paroxysms of pain. The nurse, to meet these symptoms, had dosed the infant with castor oil and with honey and water, but the former remedy had not relieved the constipation, nor the latter the vomiting. Before the child came under my notice it had been seen by Mr. Appleford (acting for Mr. Gordon Brown, of Finsbury), who informed me that the tumour, when he first saw it, was slightly larger than at present, and that a small portion of its contents could be reduced into the abdomen, leaving the bulk of the tumour firm and solid, as it was when I saw it. The labour, moreover, had been normal. The swelling, when the case came under my notice, was everywhere uniformly firm, and had precisely the consistence and general characters, as regards both its coverings and its aspect, as the cord itself; it was dull on percussion; there was not the least impulse on crying, nor could the size of the mass be diminished by pressure. The anus was quite patent, and a No. 12 india-rubber catheter passed readily about four inches up the rectum. Nothing came away with the catheter, but its introduction produced much straining. I urged upon the friends the advisability of exploring the tumour; they, however, declined any operative interference at the time, but brought the child to me again on the afternoon of the following day, Wednesday. The infant was then much worse, the abdomen much distended, and evidently very tender; the legs were kept constantly drawn up; the tongue was dry and coated, the pulse extremely feeble, and the eyes and fontanelles sunken. Nothing had passed the anus, and the vomiting had been persistent. Acting upon the presumption that an operation could scarcely render the child's condition more serious, even if it effected no good, I proceeded to explore the tumour. The mass itself had altered but little in appearance since it was last examined, beyond the fact that its colour was somewhat changed, having become greenish in some places and more purplish in others. Its consistence, moreover, was less firm to the touch, and its outline a little less regular. The changes were evidently connected with the approaching disintegration of the cord, and were equally obvious in that part of the funis beyond the tumour. I made a vertical incision along the whole length of the tumour in the middle line, and almost immediately opened a distinct sac, from which escaped about a drachm of opaque blood-stained fluid. In this sac was found about two inches of the lower part of the ileum, the whole of the cæcum, and the vermiform appendix.

The herniated bowel was very firmly strangulated, the seat of constriction being at the neck of the sac, and formed obviously by the unyielding wall of the abdomen. The mouth of the sac was nearly circular, and was about the size of an adult's thumb. The protruded intestine was of a deep claret colour, still firm and resilient. The surface of the herniated portion of the ileum was dull and sticky, and the surface of the cæcum and appendix covered entirely with lymph, and from this surface, on being handled, blood oozed somewhat freely. The aperture into the abdomen was enlarged by an incision directly upwards in the middle line, the small gut was found to be somewhat adherent to the margin of the opening, and to a small portion of the sac wall behind the margin, but the cæcum was extensively adherent to the sac by the whole of that portion of its surface that looked towards the abdomen. In attempting, first of all, to reduce the ileum a large quantity of small intestine escaped from the distended abdomen through the wound. The reduction of this proved a matter of much difficulty—a difficulty evidently due, for the most part, to the great distension of the bowel by gas. I therefore thrust the point of a hypodermic syringe into the inflated gut, and, having removed the piston, allowed the flatus to escape. The reduction now became simple, and soon all the intestine had been replaced into the abdomen, the cæcum being reduced last, its adhesions rendering its replacement slow to effect. Altogether an opening had been made into the abdominal cavity about one inch and a quarter in length. The reduced gut passed back freely into the cavity, but I failed to observe whether the cæcum was or was not provided with a mesentery. The sac was lined with peritoneum, the serous covering on the ileum being distinct enough; but the condition of the cæcum was such as to render any conclusions as to the condition of a peritoneal covering difficult to be arrived at. The edges of the wound were brought together with two harelip pins that included the peritoneum, and by four or five silk sutures that connected the integuments only. The operation was performed without any antiseptic precautions, and the wound was covered simply with dry lint secured by a bandage. Chloroform was administered. The operation was performed exactly sixty hours after birth. The child for some hours after the hernia had been reduced remained in a semi-collapsed condition, but during the evening it began to improve, and within twelve hours after the operation a copious motion was passed. Next day it was fed with the bottle, which it took eagerly and without the least recurrence of the vomiting. The pins were removed in thirty-six hours and the edges of the wound drawn together with strapping. The child's recovery was uninterrupted, and in seven days it left the hospital with the wound healed. From time to time it was brought to my out-patient department and appeared well in every respect. Three weeks, however, after the operation the child became troubled with diarrhœa, due presumedly to improper diet, and died somewhat suddenly of convulsions. An examination of the navel on the day before its death showed the scar to be firm and well healed, and so contracted as to present an appearance but little different from the normal umbilicus. A post-mortem examination of any kind was declined by the parents.

Remarks.—Congenital herniæ at the umbilicus are certainly among the most uncommon forms of rupture, and although mentioned by some few authors, do not appear to have been regarded as of great clinical importance. The majority of the cases of hernia in this situation that have been recorded have occurred in monsters, and have been associated with other and more grave defects incompatible with existence, and have been described usually as mere curiosities of mal-development. One of the most interesting points in these cases deals with the exact situation of the hernial sac, and it would appear from some accounts that the sac is more commonly situated in the immediate vicinity of the cord than located actually in its substance. Dr. James Chadwick of Boston, for example, in a pamphlet on "Rare Forms of Umbilical Hernia in the Fœtus" (1876), describes six cases of congenital umbilical hernia in fœtuses for the most part anencephalous, and in other ways greatly deformed, but in only one of these is it distinctly made out that the sac was actually in the substance of the cord itself. In the brief account of the affection given by Dr. Gross in his "System of Surgery," fifth edition, vol. ii., p. 617, the cord is spoken of as usually placed below or a little to one side of the tumour, while the rupture is described as having a distinct sac "consisting of the transparent envelop of the umbilical cord," but with no cutaneous covering. This description very closely accords with that given by Sir Astley Cooper in his "Anatomy and Surgical Treatment of Abdominal Hernia," p. 265. This description may hold good for monsters so greatly deformed as those depicted by Dr. Chadwick, but I believe it to be certainly unusual as regards the comparatively small herniæ that occur in well-developed infants born alive, and that are referred to in Sir Astley Cooper's observations.[1] Indeed, among such recorded cases as I have been able to find, five at least presented the sac in the substance of the cord itself, as it was in the present instance. From these recorded cases, also, the following facts may be adduced: The herniated gut is usually the cæcum, with more or less ileum. It is not uncommon for the coverings of the hernia to be so thin as to be transparent, and to reveal the nature of the contained gut.[2] In all cases the hernia appears to have been noticed at birth; in two instances the gut was included in the ligature applied to the funis,[3] and both these cases terminated fatally. In one instance[4] the sac ruptured soon after birth, the intestines escaping from the abdomen; they were reduced with great difficulty, but the infant recovered without a bad symptom. I have met with only one instance recorded of strangulation occurring in these herniæ. The case was under the care of Mr. Stanley of St. Bartholomew's Hospital, and is reported in the *Medical Times*, vol. ii., 1852. Symptoms of strangulation existed from birth, and the tumour appears to have closely resembled the one now described. Mr. Stanley saw the child on the day after its birth, but declined to operate; it died on the day following. In Mr. Holmes's case the cord had bifurcated, the gut occupying one of the cornua, and he refers to another case of a similar character. In one instance the hernia, after resisting all attempts at taxis, spontaneously disappeared on the eighteenth day, just a week after the separation of the funis. In the present case, moreover, attention may be drawn to the rapid healing of the wound without a bad symptom of any kind, although the abdomen had been freely opened without antiseptic precautions, and also to the early period—viz., sixty hours after birth—at which the operation was performed.

Gordon-square, W.C.

TREATMENT OF PLEURISY AND EMPYEMA.

BY JOHN E. MORGAN, M.A., M.D. OXON.,

PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY, AND PROFESSOR OF MEDICINE IN THE VICTORIA UNIVERSITY.

DURING the last thirteen years a large number of cases of pleurisy and empyema have come under my care in the wards of the Manchester Infirmary. In the treatment of these cases I have adopted various curative procedures, with a view of meeting special complications and combating symptoms of unusual gravity. In some instances these measures appeared to act favourably, and to contribute largely to the recovery of my patients. In my remarks on this subject I do not intend to classify the whole series of cases I have been called upon to treat, nor to show what proportion of these cases terminated in a return to health. Such statistics are necessarily misleading; and the conclusions drawn from them of comparatively little value. Some cases in which the symptoms are very acute, and the temperature also excessively high, are almost certain to prove rapidly fatal; others, though protracted for years, will yet eventually make a good recovery.

In this paper I propose, in the first place, to direct attention to the spirometer in the treatment of all cases accompanied by pleuritic effusion. I shall refer also to the use of compressed air in assisting to expand the occluded vesicles of the lungs. I shall further call attention to the most satisfactory methods of dealing with some of the difficulties which too often beset us in the protracted after-treatment of many chronic cases of empyema—difficulties which interfere with recovery and sow the seeds of future disease.

Since I paid special attention to the various effusions of the pleural sac, I have felt strongly that if we desire to make ourselves accurately acquainted with the variations in the amount of the fluid present from time to time in the cavity of the chest, something more is needed than the usual methods of physical examination. Percussion, auscultation, and palpation will not give us the information we require. By their aid we cannot even form a rough estimate of the amount of fluid compressing the lung where there are old adhesions. Where also the costal and pulmonary pleura are held together by those adhesions, and the pleuritic effusion is encapsulated, a comparatively small amount of fluid is sufficient to cause absolute dulness on percussion, and a total absence of the vocal fremitus, even though the portion of lung actually compressed be altogether insignificant. If we would measure the extent to which the lung is encroached upon, we shall best succeed in our object by ascertaining how far its air containing capacity is impaired. This information we can only obtain by such an instrument as the spirometer, an instrument which can estimate for us the number of cubic inches of air the lungs contain. By means of Mr. Hutchinson's spirometer very accurate and valuable information may in this manner be obtained. I have used this instrument in several cases, and am prepared to bear my testimony to its value. Still, it is not an instrument that has ever come into general use. It it cumbrous and messy; requires to be adjusted before it can be used, and is by no means portable. These objections do not apply to a spirometer invented by Dr. Jagielski, and manufactured by Messrs. Mayer and Meltzer, of London. The attention of the British Medical Association was drawn to this instrument in the year 1874 at Norwich. Ever since these instruments were introduced to the notice of the profession I have constantly used them. Indeed, I have three of them in my possession at present. I have carefully tested them in a large number of cases both in health and in disease. In healthy persons my observations coincide generally with the conclusions arrived at by Mr. Hutchinson, and published by him in an interesting and exhaustive article in the twenty-ninth volume of the Medico-Chirurgical Transactions. In this article Mr. Hutchinson shows that what is termed the vital capacity of man is modified by four circumstances. Height, weight, age, and disease. The influence of height, however, is very much more marked than that of the remaining factors. Mr. Hutchinson states that for every additional inch of height from five to six feet, eight additional cubic inches of air at 60° are given out by a forced expiration. Hence it follows that if the vital capacity of a man five feet in height is 174 cubic inches, that of a man five feet six inches will be 222; while a man of six feet will be able to expire 264 cubic inches. A very large number of observations on healthy individuals engaged in various occupations led Mr. Hutchinson to the conclusion that the vital capacity of different individuals bears a very close relation to their height—so close indeed that the results obtained from experiments almost exactly tally with the numbers of arithmetical progression.

---

[1] See on this point "Lectures on the Surgery of Childhood," by Athol Johnston, p. 41, 1860.

[2] Medical Times and Gazette, vol. ii., 1870, p. 84.

[3] Ibid, vol. ii., 1852, p. 111. Holmes's System of Surgery, vol. v., p. 820.

[4] THE LANCET, vol. i., 1873, p. 829.

This relation between height and vital capacity will be found of great value in cases of disease of the chest, especially in such a disorder as pleurisy accompanied with effusion, where by far the most important factor we have to consider is the height. Other considerations, such as those relating to weight and age, may for all practical purposes be omitted. The expression "vital capacity" signifies the number of cubic inches of air given out by the most forcible expiration following the deepest possible inspiration. It includes what has been termed the supplemental air no less than the tidal and complemental air. It does not apply to what is known as the residual air, which the lungs cannot get rid of by any effort of the expiratory muscles. This residual air, in a man of average height, may be estimated at about 100 cubic inches. The supplemental air which remains in the chest after an ordinary expiration may be set down at another hundred cubic inches; the tidal air which enters and passes out of the lungs during ordinary quiet breathing at about 30 inches; and the complemental air, or that portion which the lungs can accommodate after a deep-drawn inspiration, at an additional 100 cubic inches. Hence, when a man takes what is popularly termed a long breath, filling his lungs to the utmost possible extent, and then empties them with as much force as he is able into the blowpipe of the spirometer—when supplemental, tidal, and complemental air are together expired—he enables us to measure the air-containing resources of his lungs; in other words, to gauge his vital capacity. If, then, the spirometer in this manner indicates to us the space available within the lungs for the storage of air and for the purposes of respiration, it will readily be seen that when from any cause the boundaries of the thoracic cavity are encroached upon—when, for example, seven or eight pints of serum are effused into the pleural sac—the quantity of air which the lungs then contain must be proportionately reduced. There is no disease in which a diminution in the vital capacity is so rapidly induced as in pleurisy accompanied with effusion. In one case which I have recorded, the air income of the lungs (if I may be allowed to use the expression), fell from 250 to 80 inches in the course of forty-eight hours. Such changes we can measure with peculiar facility by means of the spirometer. This instrument teaches us whether it is necessary to perform paracentesis, and when the operation should be performed. I am in the habit of availing myself of the assistance it affords even in the acute stages of pleurisy, so soon as I discover that the amount of effusion is at all considerable, and I have never known any ill effects to result from its use.

In the very early stages of the disease, however, when the "stitch" in the side is still a troublesome symptom, we would naturally refrain from using this instrument. But so soon as even a moderate serous exudation has occurred the pain usually disappears, and then the information which it affords is very valuable. Objections have been raised to the spirometer on the ground that a certain amount of practice is required before the patient can familiarise himself with its use, and effectively empty his lungs. This objection is altogether groundless; it does not tally with my own experience, or with the far more extensive observations of Mr. Hutchinson. In making his experiments, Mr. Hutchinson directed those whose chests he desired to test to blow three times into the instrument. On each occasion the reading was noted. From these three readings a mean reading, indicating the vital capacity, was deduced. The slight difference usually observed between these several readings testifies to the general accuracy of the instrument and the readiness with which our patents learn to use it. By means of this instrument I have carefully tested in a considerable number of cases the value of some of the different remedies which have been recommended in the treatment of pleurisy with effusion. The general conclusion at which I have arrived is that whenever the amount of fluid is excessive and the disease of long standing none of them can be said materially to influence absorption. Thus in some cases I have persistently tried the most powerful diuretics, prescribing them in large and frequently repeated doses. But I never found that they exerted any decidedly curative effects. In other instances I have tested the efficacy of diaphoretics, subjecting my patients to severe courses of hot air baths, prescribing at the same time such active drugs as the jaborandi. But though excessive perspiration has in this manner been induced, and the weight of the body considerably reduced, I have never learnt from the spirometer that absorption in the pleural sac has been very largely influenced by the energetic action of the skin.

In two cases likewise I adopted a plan of treatment strongly recommended by Niemeyer. It consists in placing the patient on as dry a diet as possible, allowing him to partake of a very small quantity of liquid. Although, however, the inconvenience and discomfort to which I subjected the pleuritic sufferers was very considerable, I did not find any decided increase in the vital capacity when gauged by the spirometer. Drastic purgatives also (including such active drugs as elaterium, scammony, and jalap) have in my hands proved equally unavailing. It would appear that in these cases various internal remedies fail to promote absorption, because the pressure upon the orifices of the lymphatics prevents them from fulfilling their normal functions. This is shown by the fact that when a portion of the fluid contained within the pleura is withdrawn by the aspirator, the remainder is often speedily taken up through their agency. In other cases, again, we may assume that absorption is impossible, partly by reason of the composition of those inflammatory products which surround the effusion, partly because the effusion itself is but little prone to undergo absorption.

In using the spirometer it is my invariable practice to test the vital capacity of my pleuritic patients two or three times every week. Thus we may readily ascertain whether or not the fluid is being absorbed. In some cases we are surprised to find how greatly vital capacity is affected by what appears to be, on percussion, a comparatively moderate exudation. For example, where the area of dulness occupies less than half of one lung the spirometer frequently shows that the vital capacity is reduced, not to one-fourth its normal amount (as we would naturally expect), but to less than half the estimated standard. This is, no doubt, partly owing to the fact that the affected side encroaches to some extent on the sound side; and it is in part also due to the hyperæmic condition of the healthy lung. It must be further remembered that though the effusion occupies but half the pleural sac, the lung floats on the surface of that effusion, and by reason of the compression to which it is subjected admits comparatively little air.

The great value of the spirometer, however, consists in the information it gives regarding the ebb and flow of the fluid in the chest. If the vital capacity steadily increases, if each succeeding week the lungs admit an augmented volume of air, it is our duty to avoid all operative interference. We shall, I think, act prudently if we even abstain from inserting the needle of a subcutaneous injection syringe into the chest, for the sake of satisfying ourselves as to the nature of the effused fluid. Simple as this procedure undoubtedly is, it is not altogether devoid of risk; indeed, I have my suspicions that from this cause a serous exudation is occasionally converted into one that is purulent.

When, however, the spirometer, teaches us that the vital capacity of the chest, so far from increasing, is actually diminishing, or at all events remaining stationary, then we may rest satisfied that the time has arrived when paracentesis cannot any longer be prudently delayed. The first question we have then to decide is where should the opening be made. In the opinion of Dr. Bowditch, the thorax may be most appropriately punctured in one of the intercostal spaces between the seventh and tenth ribs, immediately beneath the lower angle of the scapula. He recommends that a spot be selected about an inch and a half higher than the lowest point at which the respiratory murmur can be heard in the healthy lung of the opposite side. It has appeared to me that the differential stethoscope is peculiarly valuable in enabling us to obtain this information, by mapping out for us the exact boundaries of the two lungs, and enabling us to measure the comparative intensity of the breath sounds on the opposite sides of the back. In a large number of my cases I followed Dr. Bowditch's advice and performed paracentesis in the dorsal portion of the thorax. Of late, however, I have given up this practice. The muscles of the back are frequently thick, and consequently it is at times no easy matter to make out the exact boundaries of the intercostal spaces. Here also we often find, on using the aspirator, that the contents of the pleural sac flow out far less readily than when the puncture is made in some other portion of the thoracic wall. This is probably owing to the trocar having entered a thick layer of fibrin, which naturally gravitates towards the dorsal aspect of the costal pleura when the patient occupies the supine position. It is not possible, however, to lay down absolutely rigid rules regarding the exact spot at which paracentesis should be performed. Each case must be specially studied and dealt with on its own merits. It may be laid down as a general rule that when the effusion is serous the puncture should be made directly in the axillary line just above the sixth rib. If, however, it be purulent, then the anterior portion of the chest should be the place selected for the operation. For, under these circumstances, we may find it expedient to keep the wound open for a considerable time. Here there is less danger of the aperture becoming occluded in consequence of the ribs colliding or actually overlapping one another, as so frequently occurs when the side contracts. Another matter of some importance (if we decide upon operating) is the instrument we should select for the purpose. In many cases I prefer such a syringe as that used by Dr. Bowditch, to the aspirator generally employed. A double perforated cork is attached to this syringe, through one of whose apertures the fluid is drawn into the syringe, while it is discharged externally through the other by a quarter turn of the regulating cork. Whatever plan of emptying the thorax be adopted, it is not advisable to remove any large quantity of fluid at one and the same time.

Among the writers who have discussed this subject, we read of six or seven pints of serum having been withdrawn at a single sitting. If we follow this practice, we shall find that in not a few instances a serous exudation will be succeeded by one which is purulent. In expressing this opinion I am well aware that I run counter to the views of so high an authority as Trousseau, who distinctly states that there is a great advantage in emptying the chest as completely as possible. This, he maintains, is the best means of putting the lung into favourable conditions for expanding freely, and consequently of expediting the cure. These views have not been generally accepted by those who have had the largest experience of this operation; for in not a few instances the lung is too firmly bound down to admit of expansion; while the vessels of the inflamed pleura are greatly distended, and the newly formed capillaries delicate and yielding. Hence we can understand that if the pressure exerted by the fluid on these vessels be suddenly withdrawn, both serum and lymph corpuscles will more readily exude. In this manner a serous effusion is converted into one that is purulent. The condition of the new vessels found in embryonic tissue is naturally favourable to exudation. If exudation be stimulated we get an over-production of cells constituting suppuration. It has further appeared to me that when the effusion is suddenly and completely withdrawn troublesome paroxysms of coughing are liable to occur, while the patient complains of a sense of constriction in the region of the epigastrium. Hence, in cases of sero-fibrinous effusion, unless the symptoms of oppression and dyspnœa be very marked, I seldom withdraw more than from twenty to thirty ounces of serum at one sitting. The removal of so comparatively small a quantity of fluid is often sufficient to stimulate absorption, which afterwards proceeds in a more satisfactory and energetic manner. After the tapping I direct the patient to inhale compressed air once or twice daily for ten or fifteen minutes from a pneumatic apparatus invented by Dr. Geigel of Wurzburg. The operation for paracentesis is repeated at stated intervals until the whole of the fluid is withdrawn. As it is withdrawn an attempt is made to expand the affected lung by pressure from within.

It is said, indeed, that in such cases the contracted airless lung fills itself from its pervious colleague during fits of coughing and other expiratory efforts, while the glottis is closed. This re-expansion of the lung may, I believe, be very much more satisfactorily accomplished by means of compressed air. *(To be concluded.)*

TINEA TONSURANS, ACCOMPANIED BY ALOPECIA AREATA.

BY J. HERBERT STOWERS, M.D.

DR. ALFRED SANGSTER'S communication to THE LANCET of July 3rd has again drawn attention to the interesting fact that occasionally true ringworm is to be met associated with alopecia. As is stated, this circumstance has not been overlooked by several authors, including Dr. Robert Liveing, who, in his work on the "Diagnosis of Skin Diseases," remarks that "tinea tonsurans occasionally produces perfectly smooth, bald, and shining patches of skin, bearing a very close resemblance to alopecia areata, and for which they may be easily mistaken." The discovery that the spores of a vegetable fungus were not infrequently found connected with alopecia, led Audouin and Gruby to advocate that area was due to their presence, and that the so-called tinea decalvans was a parasitic affection produced by the fungus, afterwards known as the "microsporon Audouini." The elaborate and comprehensive paper published by Dr. Dyce Duckworth in the St. Bartholomew's Hospital Reports for 1872, vol. viii., proves, I think, beyond doubt, the true nature of alopecia areata, so far as the microscope of the present enables us to judge.

On p. 162 Dr. Duckworth says: "The remarkable series of cases reported by the late Dr. Hillier in a large school at Hanwell has no doubt influenced the opinions of the profession upon the contagiousness of area. Dr. Bristowe is disposed to believe that these cases were probably examples of ringworm. The two diseases sometimes co-exist. Mr. Hutchinson states that area rarely shows any tendency to spread by contagion,[1] but he has recorded three cases occurring in one family, in which he found epiphitic elements.[2] I am," continues Dr. Duckworth, "unable to offer any explanation of these cases, which are carefully recorded by this most able observer, and I can only express my belief that they may have been *mixed* cases of area and tinea tonsurans." My present purpose is merely to record several cases, which have occurred under my own observation, of what Dr. Duckworth describes as being of "mixed" character, and to mention the chief points, careful attention to which will enable us to arrive, under apparently doubtful circumstances, at a correct diagnosis.

CASE 1.—The following I have copied from my notes in the case-register of the skin department of St. Bartholomew's Hospital, presided over by Mr. Morrant Baker.

James T——, aged eleven years, was first seen on Oct. 24th, 1879. It was stated that the hair was noticed to fall off about four weeks previously, over the right parietal bone. About the same time two small bare patches occurred over the occiput. Upon examination a circular bald patch was found, with a diameter of two inches and a half, situated over the right parietal eminence. The surface is smooth and shiny, and, with the exception of a few short "stumps" at the lower part, completely bereft of hair. The anterior and inferior margins are abrupt and well-defined, the contiguous hairs presenting perfectly natural appearance. Towards the posterior and upper edges the exposed surface becomes slightly scaly, and leads up to the border line, which is distinctly altered in character, exhibiting considerable branny desquamation, together with a number of irregularly fractured hairs of a dull yellowish colour, and interspersed among others of more healthy type. Some of these broken hairs I examined microscopically, and found them to be abundantly covered with spores of the tricophyton tonsurans. The few scattered stumps observable towards the lower part were "club-shaped" and "brush-like" at their extremities, but after careful preparation with ether and liquor potassæ presented no vestige of fungous element. The other two smaller patches in the occipital region exhibited solely the characters of non-parasitic alopecia.

---

[1] Med. Times and Gazette, Feb. 1858.
[2] Path. Soc. Trans., vol. vi. p. 379.

CASE 2 I saw in June last in consultation with Mr. A. Glover Williams. It was that of Bertha A——, aged seven years. The child was first noticed to have ringworm six months before. As the disease had extended the hairs became dislodged until extensive baldness resulted. The affected scalp was almost entirely destitute of hair, and the surface presented a distinct scurfy roughness, the epithelial scales upon microscopical examination disclosing mycelia and spores of the tricophyton tonsurans.

CASE 3 came under my notice in private practice at the end of last summer. The patient, a boy aged eleven years, presented three well-marked circular patches of alopecia areata, smooth, shiny, and well defined, situated over the left temporal and parietal bones. The largest, about the size of a florin, was absolutely bald, the two smaller were more or less oval in form, and presented diameters of little under an inch, with two or three fractured and clubbed hairs peculiar to alopecia areata. I may mention that the above were thought by the mother to be ringworm, and supposed to have been contracted while on a visit in the country. Upon examining the back of the head my attention was drawn to a small, slightly reddened, and scaly patch at the junction of the hairy and cutaneous surfaces, immediately to the left of the middle line, which with the aid of a lens proved to be tinea tonsurans. Seeing a few fractured and twisted hairs, I subjected them to microscopical examination, when spores of true ringworm fungus were visible. This had been overlooked previous to my seeing the lad. Microscopical examination of the hairs upon and around the three other bald places, with reagents, proved the absence of parasite.

CASE 4.—Mr. Morrant Baker informs me that he has a case now under his care in private practice in which alopecia areata is combined with ringworm of the scalp. The patient is a little girl, eight years old, and the ringworm is extensively distributed over the crown of the head, while in the post-mastoid and suboccipital regions there is on each side a nearly symmetrical smooth, almost hairless, patch of alopecia, the short broken hairs from which were found under the microscope to present the appearance characteristic of alopecia areata. Some slight redness was noticed in these situations two or three months before the ringworm attracted attention, but the baldness was not observed until about the time of the discovery of the latter disease.

In Case 1, besides the two small patches of circumscribed alopecia, it will be observed that the third or large one presented two sets of characters. At the anterior and lower part the surface was pale, smooth, and shiny, with an abrupt and well-defined outline. Upon it a few short hair-stumps are seen lying loosely in their follicles from atrophy of the roots. Immediately above this each stump becomes distinctly darker in colour and enlarges "club-shaped," and terminates in a ragged "brush-like" extremity. This last condition is produced by the line of fracture occurring through the site of the dilated or bulbous portion observable in the early stage, and brought about by separation of the fibrillæ. Frequently refracting sebaceous granules are seen in clusters along the margins of the hair-shaft attached to the epidermic imbricated scales, and likely to be mistaken for mycelia and spores. Proper reagents will, however, immediately disclose the fallacy. Again, as we approach the upper and posterior portion of the described patch, slight branny desquamation commences, until at the margin, which is irregular and ill-defined, broken, twisted, dull sulphur-coloured hairs are seen peculiar to true ringworm, and thickly studded with spores, and mycelia of the vegetable parasite trichophyton. This case illustrates well the coincidence of the two affections, and goes far to explain the mode in which, when patches of tinea tonsurans and alopecia areata coalesce, the latter and more conspicuous one is mistaken to be of parasitic origin.

Cases 3 and 4 serve well to support this view. In each of them we have co-existing the two diseases in separate parts of the scalp, quite distinct from each other. Very probably had the patients not been examined at the time they were, by gradual extension the several patches would have run together as in Case 1, and a similar condition would have been brought about.

In Case 2, as I have said, "the child's head was almost entirely destitute of hair," and in consequence those who yet cling to the belief that alopecia is parasitic may look upon this as an example of the same. But my notes further say, "the surface presented a distinct scurfy roughness, the epithelial scales upon microscopical examination disclosing mycelia and spores of the trichophyton tonsurans," indisputable evidence of true ringworm. Hence the difference between the two: the roughness owing to furfuraceous desquamation, the presence of mycelia upon the epithelial scales, the existence here and there of stubby hairs, broken and disorganised by spores on the one hand, and, on the other, the absence of the smooth, shining, more or less well-defined ivory-like baldness characteristic of alopecia. Future investigation will doubtless prove more certainly the true cause of this latter affection. It is in the hope that other observers, whose experience extends over a longer period than my own, will record their views upon the connexion, if any, between these two interesting diseases, that I am led to desire the publication of the accompanying notes, and if among them so careful and scientific an investigator as Dr. Sangster will do so, for I observe in his short communication he does not express any definite opinion of his own, I, for one, shall be really obliged.

Finsbury-circus, E.C.

ON CONGESTIVE DYSMENORRHŒA.[1]

BY G. ERNEST HERMAN, M.B. LOND.,
ASSISTANT OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL, PHYSICIAN TO THE ROYAL MATERNITY CHARITY, HONORARY LIBRARIAN TO THE OBSTETRICAL SOCIETY OF LONDON.

IT has long been customary for writers upon the diseases peculiar to women to describe three kinds of dysmenorrhœa—namely, neuralgic, *congestive*, and mechanical or obstructive. In the present communication I propose to consider first briefly the present usage of the term "congestive dysmenorrhœa," and then what it seems to me we should mean by it. It is necessary to comment upon its present meaning because although nearly all authors employ the term, yet there is no agreement as to what cases should be included under it, and consequently the term has no definite and generally accepted signification. There are two chief usages of the term—the one wide, embracing every case of menstrual pain in which congestion is presumed to be present, and to contribute to the pain, and therefore including a great number of different conditions; and the other narrow, applying the term only to cases in which congestion appears to be the sole morbid condition present, cases which are so infrequent, and perhaps so imperfectly described, that their existence has been doubted. The use of the term with the wider meaning I will illustrate by a quotation from the work of Dr. Galabin. I refer to it as being the most recent manual, and that which contains the clearest and shortest account of commonly accepted doctrines. He says,[2] "the old division of dysmenorrhœa, or painful menstruation, into the neuralgic, congestive, and obstructive forms, is still the most useful and comprehensive. Most cases of dysmenorrhœa, however, do not belong exclusively to one or other of these classes, but partake in some degree of the character of two or even of all three of them. The names therefore should only be understood as indicating the preponderating element in each case.......By some authors separate classes are made of inflammatory, ovarian, and membranous dysmenorrhœa. Inflammatory dysmenorrhœa should, however, rather be regarded as a variety or subdivision of congestive dysmenorrhœa, since in inflammation the pain is mainly due to the concomitant congestion, and it is frequently impossible to draw an absolute line between congestion and inflammation. Ovarian dysmenorrhœa, again, is a variety of congestive or inflammatory dysmenorrhœa, and membranous dysmenorrhœa is one form of obstructive dysmenorrhœa, commonly associated with signs of congestion. Three forms, however, of inflammatory dysmenorrhœa specially deserve attention—(1) that in which the pain in menstruation is a symptom of fresh and active inflammation; ...... (2) that in which the dysmenorrhœa is the sequel of peri-uterine inflammation; ...... (3) that in which it is the result of corporeal endometritis." This quotation shows how many and how different are the forms of disease commonly brought together under the title of congestive dysmenorrhœa. In every point of the paragraph there are other authorities in full accord with Dr. Galabin, so that his statement is not the expression of an isolated opinion. To prove this statement, I may refer to Thomas's work, who defines "congestive dysmenorrhœa" as that due to hyperæmia of the pelvic tissues, and says, "it may result from almost any pelvic inflammation, or from any influence which exaggerates and prolongs the congestion excited by ovulation. Chief among these may be mentioned—general plethora; exposure to cold and moisture; sudden mental disturbance; sluggishness of portal circulation; displacement of the uterus; fibrous tumours; areolar hyperplasia; endometritis; peri-uterine cellulitis; pelvic peritonitis;"[3] and to Churchill, who includes under the term cervical endometritis, retroflexion, and membranous dysmenorrhœa,[4] the latter form of painful menstruation being also classed as congestive by West[5] and Scanzoni.[6] Atthill makes it also comprehend pain in the ovary.[7] Heywood Smith adopts the view of Thomas.[8]

---

[1] Read before the West Kent Medical and Chirurgical Society.
[2] Student's Guide to the Diseases of Women, p. 328.

If we use it thus, we make the term "congestive dysmenorrhœa" comprise a number of conditions which differ widely as to their causes, treatment, and prognosis. Consequently when applied to a case it carries with it no information, and we must go further before we can understand the disease, or do anything for its relief. Therefore used in this sense, the term seems useless. It is true that congestion is present, as it usually is at the menstrual period; but in many of the conditions enumerated it is not certain that the congestion is the cause of the pain, and that neuralgia and obstruction are absent. The objection which Schrœder makes to this use of the term seems to me a just one. He says, "We ought not by any means to include under the head of dysmenorrhœa those pains accompanying the period, and which are commonly designated as congestive dysmenorrhœa, for in these cases the regular symptoms of uterine diseases are only intensified by the menstrual congestion."[9] The other and narrow meaning of the term to which I have referred is thus defined by Simpson: "There is usually nothing to be found further than an exaggeration of the ordinary phenomena of menstruation. At every menstrual period there occurs a certain amount of congestion. ...... This congestion, which goes on not only in the uterus but in the ovaries as well, may, and sometimes does, rise beyond the normal standard, and then uneasy sensations may be produced, and all the symptoms of perfect dysmenorrhœa."[10] This is the meaning given to the term by the more recent French writers. Monat divides dysmenorrhœa into two classes—"idiopathic" and "symptomatic." By "idiopathic" he means that which is not associated with any appreciable lesion either of the uterus or of other parts; by "symptomatic," that which results from such lesions. "Idiopathic" dysmenorrhœa he divides into "nervous" and "congestive"; and "symptomatic" into inflammatory, mechanical, and membranous. Inflammatory dysmenorrhœa, he says, is "that which shows itself during the course of acute or chronic inflammation of the uterus or the peri-uterine tissue. ...... The symptoms of this dysmenorrhœa are those of congestive dysmenorrhœa, complicated and aggravated by the symptoms of uterine or peri-uterine inflammation. The diagnosis of inflammatory dysmenorrhœa depends entirely upon the discovery of inflammatory lesions of the uterus or its appendages."[11] Courtz[12] adopts the same classification. If we compare this with the quotations previously made from the works of Simpson and of Thomas, it will be plain that Monat's congestive form of idiopathic dysmenorrhœa is that which corresponds to the definition of Simpson; while congestive dysmenorrhœa, according to Thomas, includes not only this, but Monat's inflammatory form of symptomatic dysmenorrhœa. And other authors give the term a still more comprehensive meaning.

The foregoing will be sufficient to show that congestive dysmenorrhœa is not a term which has a definite and generally accepted meaning; but that, on the contrary, it has been used in several more or less wide significations. It results from this, that each one who ventures to write upon or speak of congestive dysmenorrhœa must inquire for himself what is the best way in which he can use the term in question. Unless it can be employed with some exact meaning it had better be abandoned.

The simplest way of deciding what a term ought to mean is by looking to its natural etymological signification. Congestive dysmenorrhœa suggests at once menstrual pain caused by congestion. The mere presence of congestion cannot be a distinctive mark of congestive dysmenorrhœa, for some amount of congestion is present at every monthly period. We cannot make the degree of this congestion the criterion, for we have no means of measuring its amount. We have therefore no way of defining one degree of menstrual congestion which is natural and another which is morbid, except by assuming that the congestion which is accompanied by symptoms severe enough to demand treatment is excessive in amount and the cause of such symptoms. But to do this is to beg the question. The comprehensive definition given to the term by Thomas and others takes it for granted that in all cases in which there is a greater degree of congestion of the pelvic organs than is usual, and at the same time a greater degree of pain at the menstrual period, that the congestion is the cause of the pain. To use the term in this way seems to me objectionable—first, because the causes which may lead to congestion of the pelvic organs and consequent pain are so numerous that even if we are sure that congestive pain is present, we have done nothing for the patient until we have gone further, and found out its cause; and in most cases it will be useless to treat the congestion directly, without removing that which is setting it up. Therefore no practical end is served by grouping all these different cases under a common epithet. And if there be no practical advantage in it such a nomenclature is only defensible if some leading fact as to the nature of the cases is expressed by it. If there be cases included in the group in which it is not certain that the pain is due to congestion, it cannot be held that the term "congestive dysmenorrhœa," used in this wide sense, imparts knowledge any more than it helps in treatment. It therefore seems to me preferable to call these cases by the name of the disease of which the dysmenorrhœa is a symptom rather than by a general phrase which serves no useful purpose.

The only way in which it seems to me that we can make the term "congestive dysmenorrhœa" useful clinically is either by restricting it altogether to those cases in which there is reason to think that congestion, or a slight degree of inflammation, is the sole or chief morbid condition present; or at least, by following the French school, and drawing a distinction between the cases in which the congestion is a part of some definite disease of the pelvic organs, and the menstrual pain an exaggeration of the symptoms of that disease (symptomatic); and those in which the dysmenorrhœa, presumed to be due to congestion, is the patient's only trouble (idiopathic). Perhaps it would be better to speak of the latter as primary, of the former as secondary, congestive dysmenorrhœa. In the remainder of this paper I propose to speak only of primary congestive dysmenorrhœa.

My reason for bringing this subject forward is that I believe such cases exist, although they are not common, and that they have characteristic clinical features, although they have not been adequately described. I have found allusions to these cases which showed me that I was not singular in my clinical experience or in my interpretation of it. Believing, therefore, that these cases form a class capable of being more exactly defined, I shall try to contribute towards doing this.

The definition of congestive dysmenorrhœa given by Simpson, and which I have already quoted, applies to these cases, but it is of no practical use, being hypothetical only; he does not narrate or refer to any cases of the kind, or give any information as to how such cases are to be recognised, if they exist. Other authors, among whom I will name, but need not quote, Aran,[13] West,[14] Monat,[15] and Courtz,[16] though they describe a class of cases under the title of congestive dysmenorrhœa, yet do so in vague language, without pointing out any distinctive marks, so that their description does not help one to identify the cases. West, however, points out that there are two forms, one in which menstruation is profuse, another in which it is scanty. This I think a very important distinction, and I shall refer to it again. Barnes refers to the subject in a manner which well displays the present position of the question. Evidently accepting the same definition of the term as Simpson, he says: "Of course, in the case of simple congestion, we assume a normal uterus as to structure, form, and position. ...... But this coincidence I believe is rare. ...... What is the cause of this congestion? We can hardly conceive the idea of primary congestion. This condition is almost necessarily the consequence of some morbid process or injury. These are manifold."[17] The question that arises, therefore, is whether there is such a thing as dysmenorrhœa due to congestion of an otherwise healthy uterus. It is undoubtedly rare. Scanzoni[18] says he has never met with it except from "the irritation of the genital apparatus which depends on the sexual functions," and "certain affections of more distant organs which cause various troubles in the circulation," and may produce engorgement of the uterus. Byford says he has never seen a simple case of congestive dysmenorrhœa. Others, among whom I may instance Beigel[19] and Gasserow,[20] reject the term altogether. It may be presumed from their doing so that they recognise both the inutility of applying the term to a great number of widely different morbid conditions, and the rarity of the cases in which congestion is the only departure from health present, and that they have not found the descriptions commonly given of such cases correspond to any definite group of phenomena met with in practice.

The present usage, therefore, of the term is this. Some writers apply it to so many different conditions that it becomes valueless. Others apply it to a small class of cases rarely met with. A third group banish it from their nosology. Whoever then would apply the term congestive dysmenorrhœa to cases in which congestion is the sole morbid condition present, has to show reason for thinking that such cases exist, and to point out the marks which distinguish them.

(To be concluded.)

CASE OF FATAL SUPPRESSED HÆMORRHAGIC VARIOLA COMPLICATED WITH RENAL CALCULI.

BY R. D. R. SWEETING, M.R.C.S. ENG.,
MEDICAL SUPERINTENDENT OF FULHAM SMALL-POX HOSPITAL.

FLORENCE Y——, aged ten years, a pale, strumous-looking girl, was admitted into Fulham Hospital on the afternoon of Jan. 8th. She was sister to two other patients who had been admitted with variola on Dec. 29th and Jan. 7th respectively, and occupied the same room. Her illness began the day before with vomiting, backache, and some suppression of urine. — Family history: Father and mother "delicate," the former having succumbed to some chest complaint; brothers and sisters subject to scrofulous swellings and ulcerations.

On examination only a few faint non-typical red papules were seen, and these on the arms. She complained of intense nausea, and her temperature was 99·4°. She vomited several times during the afternoon and evening, and the egesta were once observed to contain a slight tinge of blood. Evening temperature 99°. When seen at midnight, the child was restless, lying on her abdomen, retching occasionally, and crying with severe pain over the loins. Had passed no urine since admission, though several attempts at micturition had been made. The bladder appeared to be full, and orders were given to catheterise if necessary. However, soon after this she passed a large motion mixed with urine, which could not be collected, but which, as far as could be judged, was high-coloured, and not bloody. At 6 A.M. on the 9th, her mouth and hands were suddenly observed to twitch violently, her surface became blue, blood of a red colour issued from the oral cavity, and she expired in a few minutes.

At the necropsy, thirty-two hours after death, on opening the abdomen, the anterior wall and lesser curvature of stomach were seen to be dark and mottled. On raising it the posterior wall was black with extravasation, and the tissues around the pancreas and the pancreatic and splenic vessels were infiltrated with a large subperitoneal hæmorrhagic clot, which also extended downwards on the left side of the spine for some inches. The interior of the stomach presented numerous hæmorrhagic stigmata. The peritoneal surface of the small intestine and the mesentery itself presented venous extravasations in their substance; mucous lining of former intensely congested. Spleen very soft, and exuding thick venous blood on pressure. Liver-substance soft and friable; vessels on exterior congested and arborescent; portal vein enormously distended. Basic congestion of lungs, without consolidation. Both kidneys were purple with congestion, but in addition the infundibula of the left presented a sacculated appearance, each pouch or recess containing one or more calculi. These consisted apparently of urates, were twenty-two in number, and varied in size from a mustard-seed to a good-sized thumb-nail, and in weight from half a grain to forty-four. No other calculi were found in the peritoneal cavity, ureter, or bladder. The latter organ contained some clear pale urine of acid reaction, and non-albuminous; muscular wall somewhat hypertrophied; no hæmorrhages. Ureters and reproductive organs apparently normal.

Remarks.—This case seems worthy of notice, not only for the abeyance of objective manifestation of the most virulent form of variola, the suddenness of death, and the curious complication that was found, but also clinically for the community of the symptoms to both conditions. There seems to be little doubt, from the history of infection and the visceral lesions, that this was a true, though suppressed, case of hæmorrhagic variola; but the question remains how much of the nausea, retching, and vomiting, and of the lumbar pain and suppression of urine was due to this, and how much to nephritic colic. The convulsions immediately preceding death seemed to be the only sign differential of the latter, suppression of urine being a not altogether rare phenomenon in the course of the former.

Fulham Hospital, W.

NERVE-STRETCHING IN ANÆSTHETIC LEPROSY.

BY GERALD BOMFORD, M.D. LOND.,
BENGAL MEDICAL SERVICE.

THE practice of stretching the nerves in leprous anæsthesia was first brought to the notice of the profession by Dr. Edward Lawrie, then of the Medical College, Calcutta, but now Professor of Surgery, Lahore.[1] The operation has since been performed in a considerable number of cases, but in only a few has it been possible to observe the result for any length of time afterwards, so that it is still undecided how far the improvement is persistent in the majority of cases. The following case is remarkable on account of the fact that the ulnar nerve broke completely across as soon as traction was attempted, and that this accident made no difference in the ultimate result.

The patient, a line-man, aged forty, employed as a common labourer on the roads, came to the Simla Charitable Dispensary on Aug. 5th, complaining of loss of power in his hands, which inconvenienced him when working. His left hand was markedly wasted, the muscles supplied by the ulnar nerve being so atrophied as to have almost disappeared, and the grasp of the hand was very weak. There was also complete anæsthesia of the ulnar side of the left wrist and hand. In the right hand there was well-marked anæsthesia of the ulnar area, but the wasting of the muscles was very much less than on the left side, though the grasp even of this hand was decidedly weak. The right ulnar nerve could be felt through the skin above the elbow as a uniformly thickened cord about three times the size of a normal ulnar nerve. The left nerve was enormously thickened, but not uniformly so. High up in the lower third of the arm it was as large as one's middle-finger, while at a point lower down, about half an inch above the condyle, it suddenly diminished to about the same size as the nerve of the right arm.

The operation was performed on Aug. 6th. The nerve of the right arm was easily exposed, and, except in the matter of size, presented a normal appearance. It was thoroughly stretched and incised longitudinally, and the wound, stitched with a catgut suture, was dressed with antiseptic gauze. This and the operation on the left arm were both conducted under strict Listerian precautions. The nerve of the left arm hardly resembled a nerve at all. It was greatly thickened and nodulated, and so adherent to the surrounding tissues that it was very difficult to raise it from its bed, so as to pass the finger round underneath it. After this difficulty had been overcome, on the first attempt to stretch the nerve, it broke at the point mentioned above, where there was a sudden diminution in size. After this accident I separated the two ends of the nerve, as far as possible, from the tissues to which they adhered, and joined them by an ordinary thick catgut ligature, dressing the wound as before.

Result.—In the right hand sensation was apparently completely restored by the operation, and the muscular strength rapidly returned, so that before he left the hospital the grasp was as powerful as that of most men. The dressing was opened for the first time on August 13th, a week after the operation, and the wound found to be completely healed. In the left hand sensation began to return two days after the operation (August 8th), on which day it was well marked on the ulnar side of the fourth finger, and every day from this date a distinct increase of the sensitive area could be noted. As the patient complained of some pain in this arm the dressings were opened on August 12th. The wound was firmly healed except in the centre, where the suture had caused slight inflammation. This disappeared on its removal, and a few days afterwards the incision had cicatrised completely. By August 17th sensation was restored over the whole of the previously anæsthetic area with the exception of the extreme tip of the little finger. The grasp of the hand was now very fair, though there was still an evident wasting of the muscles. As he was anxious to begin work again, he was allowed to leave the hospital on this date. I have not seen him since, but he is now (Nov. 30th) working on the roads, and is reported by his friends to be quite restored to health.

Fort William, Calcutta.

The Levee.—At the Levée, held on Monday at St. James's Palace, by the Prince of Wales, on behalf of Her Majesty, the following members of the medical profession were presented to His Royal Highness:—Dr. John Watt Reid, Director-General of the Medical Department of the Navy, on appointment as Hon. Physician to Her Majesty, by the Secretary of State; Brigade-Surgeon Oliver Barnett, on promotion, by the Adjutant-General; Surgeon-Major George J. H. Evatt, on return from Afghanistan, by the Adjutant-General; Surgeon-Major R. T. Lyons, M.D., Bengal Army, by the Secretary of State for India; Surgeon W. M. Collins, M.D., Royal Horse Guards, by Field-Marshal Lord Strathnairn, G.C.B., &c.; Surgeon Raglan W. Barnes, by the Adjutant-General; Surgeon T. Moloney, 3rd Sikhs, by Major-General Sir F. Roberts, V.C., K.C.B.; Surgeon Frank Smith, 2nd Kent Artillery Volunteers, by Lieutenant-Colonel Edwin Hughes; Surgeon Michael Ronan, R.N., by the Director-General of the Medical Department of the Navy; Surgeon Andrew Duncan, M.D., on return from Afghanistan, by Major-General Sir Frederick Roberts, V.C., G.C.B.

GUY'S HOSPITAL.

SURGICAL CASES.

(Under the care of Mr. Bryant.)

Vesical Calculus; Lateral Lithotomy; Abscess opening through Umbilicus; Recovery; Remarks. (From notes by Mr. Palmer.)—Jas. B——, aged five, was admitted into Lydia ward on Nov. 8th, 1879. Eighteen months before admission the child was in the Evelina Hospital with swollen prepuce, and some general eruptions on the head and limbs. At that time the mother noticed that the urine was thick, but as there was no difficulty in passing the water, nothing was suspected. Four weeks before admission the child was noticed to pass his urine in drops, and with great pain. On Nov. 7th, not having passed urine for twenty-four hours, it was taken to the hospital, when the water was drawn off. Two days later the house-surgeon passed a sound, and found a small stone.

On admission, patient was an unhealthy-looking child. The penis was somewhat red and swollen, and the prepuce was rather long; the child passed water frequently in the bed; the water seemed to pass "with a rush," and caused the child to shriek with pain.

On Nov. 11th the child was put under chloroform, and lateral lithotomy with Key's straight staff was performed, and a small (probably lithic acid) calculus was removed. One artery was twisted, and a sponge was introduced into the wound. For an hour or two after the operation hæmorrhage caused some trouble, and was controlled by pressure.

On the 19th patient passed urine by incision. The temperature was normal.

On Dec. 5th the wound did not appear to be closing, and the child had not passed a drop of urine by the urethra. A catheter was passed, but no obstruction was encountered in the urethra.

On the 10th urine passed by the urethra for the first time since the operation; the wound was closing; the urine was turbid, and had acid reaction, but cleared on boiling; no albumen present. Temperature normal.

On the 22nd an induration in the abdominal wall, extending up to the umbilicus, had appeared, and some fluid smelling like urine escaped from the upper part of the induration, near the umbilicus.

On the 28th some pus came from the same opening from which the urinous fluid escaped to-day.

On the 29th the wound in the perineum was quite healed; the child could retain his urine for four or five hours; the induration in the abdominal wall was less, and localised to the middle line, but could still be made out; the sinus from which the pus, &c., escaped had closed.

On the 31st he was discharged cured. He was able to pass urine without pain, and to retain it some hours. No signs of abscess were present.

Remarks.—The formation of a urinous abscess, and its discharge from the umbilicus after the operation of lithotomy, is a very unusual occurrence, and in the case related it is difficult to explain, as the operation was not complicated with any difficulties, nor was there any evidence of severe bladder disease beforehand to account for it. Still, there can be no doubt as to the fact, for urine escaped through the umbilicus, together with pus. Mr. Bryant was disposed to think that some ulceration of the bladder had existed before the operation, and that perforation with extravasation had taken place about the fundus of the organ, and, as a consequence, the formation of an abscess. Since he had seen the same series of events occur in cases of stricture.

Incontinence of Urine seven years after Passing Stone; Phosphatic Concretion in Bladder; Washing out Bladder; Relief. (From notes by Mr. H. H. Wright.)—Esther S——, aged thirty-five, was admitted into Lydia ward on June 2nd, 1880. She was a married woman, and mother of three children. Ten years before admission she had typhoid fever, and after this she was troubled with her water. It was scanty, and caused pain when passing. Seven years before admission she passed a large stone, and since, on and off, she had suffered with urinary trouble and incontinence. She had passed gravel at times.

On admission she complained of pain down the back and in the loin. Her general health was not bad. Urine was acid and blood-stained, and was constantly dribbling.

On June 4th she was put under chloroform and the bladder was examined, and a copious phosphatic deposit was found. Next day the bladder was washed out with warm water. A week later she was able to retain urine for a quarter of an hour. From this time she continued to improve, and on July 16th she left the hospital, well able to retain her urine for two hours, and to pass it without pain. On June 28th the temperature rose to 103°, but fell next day to 100°. On July 2nd it was normal, and did not afterwards rise above this level.

Piece of Catheter Broken in Bladder; Formation of Stone; Cystotomy; Old Perineal Section; Well. (From notes by Mr. Pitt.)—Thos. H——, aged forty, was admitted into Job ward on June 19th, 1879. He was married, and his wife had had one child. He had had gonorrhœa twice, last time sixteen years ago, and had always since had difficulty in passing water. In December, 1874, he was admitted under Mr. Bryant, and Syme's operation was performed for stricture and extravasation of urine. He remained in hospital until September, 1875, and was then discharged convalescent, but passing his urine through the perineum, the penile portion of the urethra being quite obliterated. Since then he had always passed a catheter regularly about every third week. Four months before readmission, when using a No. 4 catheter part broke off, and remained in the bladder. A No. 8 was passed frequently afterwards. About a month later he began to feel a burning sensation at the neck of the bladder; his water became dark, and deposited a thick light-coloured sediment.

On admission he seemed in moderate health. Pulse and temperature normal. When standing he passed water by the perineal opening. There was no blood or albumen in the urine. The meatus urinarius was quite closed, and had been so since he was in the hospital four years before. On June 24th he was put under chloroform, and lateral cystotomy was performed, the staff being introduced through the perineum. A piece of catheter, thickly coated with phosphates, was removed, measuring about three-quarters of an inch by one-third of an inch.

Everything went on well, and on July 8th the patient was discharged. The incision was nearly granulated up, and the patient was able to retain his water as usual. Temperature never rose above normal.

ROYAL INFIRMARY, GLASGOW.

CASE OF LEAD POISONING, ENDING IN CONVULSIONS AND DEATH.

(Under the care of Dr. CHARTERIS.)

FOR the following notes we are indebted to Mr. J. Macpherson Lawrie, resident physician.

William W——, aged sixteen, worker in a pottery, was admitted on the 22nd September last, complaining of paralysis of both wrists, of six weeks' duration. The family history was unimportant. The boy had been employed in a pottery in Glasgow for the last five years.

At a certain stage of the manufacture of earthenware, the various products are rubbed against each other in order to smooth away any roughnesses and irregularities. In this way a fine dust is disseminated, containing a small percentage of lead. At a later period they are dipped into a thick glazing solution containing 10 per cent. of white lead, and afterwards placed on a convenient perforated shelf to drain. The boy's duty was to lift the articles from the shelf on to another receptacle, for removal to the furnace. Most probably the poison had been introduced into the system through eating food with dirty hands.

The patient was in fairly good health till six weeks before admission, when his attention was attracted to a slight weakness in both wrists, which he thought due to overfatigue, and paid no attention to. This symptom gradually became more marked, and in the course of a week he was unable to raise his hands in the slightest degree. He remained at his work, and fell off in general health. About a month after the commencement of his ailment he suffered from cramps, occurring chiefly at night, in front of both thighs. These were followed by severe pain in his abdomen, accompanied by constipation. Under the influence of remedies the abdominal symptoms entirely disappeared in four days, and his bowels returned to their normal condition.

On examination the patient was found rather emaciated, with a heavy exhausted appearance, and in a very unsatisfactory state of health. When his arms were raised, the hands hung down in a helpless manner, like the forepaws of a kangaroo. The muscles of both arms were wasted and soft. The action of the supinator longus, when the forearm was extended against the patient's will, was found as usual intact. An interrupted electrical current applied over the extensor muscles was followed by no response. On the flexor aspect slight contractions of the fingers were produced. His gums exhibited the characteristic blue line. His teeth were coated with tartar, and somewhat discoloured. The abdomen was quite natural in appearance, soft, and elastic, and pressure caused no pain. His pupils were dilated. The sight was quite natural. The pulse was rather weak and about 70 per minute. His urine was found to have a specific gravity of 1012, neutral, of pale colour, without sediment, and without albumen; phosphates appeared on heating, but otherwise the physical examination yielded normal results.

The patient was put on six grains of iodide of potassium three times a day, and nourishing food, with maltine. Three days afterwards he complained of very severe cramps in the knees. They were relieved for a time with equal parts of belladonna, opium, and chloroform liniments, applied on lint, with a poultice over all. Subsequently the cramps returned, and proved extremely obstinate under treatment. The iodide of potassium was reduced to three-grain doses, and subsequently replaced by the bromide in two-grain doses every four hours without any relief to the symptoms. On the 30th, about 7 A.M. (eight days after admission) the nurse on night duty reported that the patient was getting into a "stupid condition." He was visited at once and found in a semi-comatose state, replying to questions in a vague manner when roused up. In the course of ten minutes he suddenly uttered a loud cry and was attacked with severe clonic convulsions, first on one side of his body (the right), then on the other, involving the head as well as the limbs, and latterly extending to the trunk. These symptoms were accompanied by complete unconsciousness, insensible and dilated pupils, foaming at the mouth, retracted abdomen, involuntary micturition, with a pale, clammy face and rapid and forcible action of the heart. In a few minutes the convulsions ceased, but he still remained comatose. Within the course of two or three hours he had nine or ten repetitions of the attack. During the remainder of the day he lay in a restless state with dilated pupils, but could not be got to answer any questions. His parents stated that they had never observed such symptoms before in the boy. Next morning his condition was the same. His bowels were cleared out with sulphate of magnesia assisted by an enema of soap and water. Chloral hydrate was administered in one and a quarter grain doses every hour, the bromide of potash being discontinued. In the evening his pulse became very rapid, breathing rather stertorous, and temperature 102°. On Oct. 2nd his urine was again examined and found to contain a good deal of albumen, but no lead was detected either with sulphuric acid or iodide of potassium. On Oct. 3rd he was evidently sinking. Towards night his breathing became very shallow and hurried—over sixty respirations per minute. His pulse was weak and thready and about 130. He sank very gradually, and death took place at 11.50 P.M.

Remarks.—In this case the epileptic symptoms commenced eight days after admission, and remained till he expired, nearly four days afterwards. During this period he had only one or two snatches of sleep for about half an hour at a time. As far as could be ascertained he was only conscious on one occasion, when he recognised and named his mother and brother. He took nourishment well all through, averaging about two pints of milk and beef-tea each in the twenty-four hours. The attacks of convulsions occurred at intervals of about two hours, diminished to one hour towards the end, and were all marked by the same characters as those first noticed.

A partial post-mortem examination was made, permission being only granted to examine the head, and to a limited extent the abdomen. The brain presented to the naked eye nothing abnormal. The organs of the abdomen were also apparently healthy. Portions of muscle from the left fore-arm were excised, and after being hardened in alcohol and solution of chromic acid, fine sections were made; these sections were stained with logwood, and subjected to microscopic examination. For the sake of comparison, the supinator longus was taken as normal, and with it was compared the extensor carpi radialis longior. In the latter, which was one of the muscles paralysed, there were observed, even in untinted specimens, parts in which the muscular fibres were markedly narrower than normal. This condition was not present everywhere, but, on the contrary, there were places where the cylinders were of normal diameter, this being confirmed by their measurements being the same as that of the fibres in the supinator longus. From a series of measurements the narrowed fibres were found to be on the average about half the diameter of the normal ones. The narrowed fibres existed in groups, although there were occasional single fibres of a narrow diameter. The transverse striæ in both sets of fibres were found to be equally distant, indicating that the narrowing was not due to a different state of contraction. It was also observed that in the narrowed fibres the transverse striæ were very much less marked than in the normal, being sometimes almost, or entirely, lost. These conditions were easily made out in unstained specimens, but the condition of the muscular nuclei was best determined in specimens treated with logwood. In the paralysed muscle it was at once seen that the nuclei were more abundant than in the normal, and this was, to a slight extent, the case even in fibres of nearly normal diameter. But when the narrow fibres were examined an enormous increase of the nuclei was observed, these being closely set, and in some cases almost concealing the fibres. It is impossible to dissociate these two conditions—increase of the nuclei and narrowing of the fibres, and they both indicate a marked nutritive change in the muscle. It is to be added that in some cylinders of the affected muscle there was a transparent, glassy condition, which has been variously designated as hyaline and colloid degeneration, and which is met with in the muscles in typhoid fever, &c. This was not present in the narrowed fibres, and is probably of little importance in connexion with the pathology of this disease.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Two Hundred Additional Cases, completing One Thousand Cases of Ovariotomy.—Development of a Layer of Elastic Fibres in Duct Cancer of the Breast.—Trephining in Epilepsy.

THE ordinary meeting of this Society was held on the 22nd inst., J. E. Erichsen, Esq., F.R.S., President, in the chair. The chief contribution was a paper by Mr. Spencer Wells, summarising the results of two hundred cases of ovariotomy, completing one thousand cases under his care. The President complimented Mr. Wells in glowing terms, and observed that the subject had been so recently and fully debated that there was little room for discussion.

The following is an abstract of the paper "On Two Hundred Additional Cases, completing One Thousand Cases of Ovariotomy, with Remarks on Recent Improvements in the Operation," by Mr. T. SPENCER WELLS. The author presents in a table (similar in form to those in which he has brought before the Society all his cases of ovariotomy up to the eight hundredth), the particulars of 200 additional cases. The mortality of the ninth series was seventeen, of the tenth, eleven. Among the 1000 patients 231 have died and 769 recovered; but the mortality has steadily diminished from thirty-four in the first hundred to eleven in the last. Since the eight hundred and eighty-eighth case all the operations have been in private practice, and all have been done antiseptically, the result being a mortality of 10·6. The author inquires how far this lessened mortality is due to antiseptic precautions or to other recent improvements in the mode of operating, describing in detail various modifications in each step of the operation. —The PRESIDENT said he would be expressing the feelings not only of the Society, but of the profession and public generally by conveying their very best thanks to the illustrious author of this great work. For no man had done such a work in surgery as to have recorded 1000 cases of any one great operation with so small a mortality. Nothing can redound more to the credit, not only of Mr. Wells, but of surgery that such great results had been achieved by him. "I have lived," continued Mr. Erichsen, "through the whole period covered by the operation, and have been present at meetings of this Society when the introduction of the operation was being discussed; and I cannot but call to mind the obloquy (in which I never myself shared, for I performed the operation myself until I left it in better hands) which attended the operation and the operator. It is something to have lived through an epoch of surgery which has seen an operation of this magnitude not only survive that obloquy, but become one of the most successful operations in surgery, when performed with sufficient care, attention to detail, and, of course, personal skill. Surgeons may go further, and say this, that surgery is more indebted to obstetricians (I do not use that word—which I abominate—gynæcologists) for great improvements effected in operative surgery, for it is to them we owe the great precautions which, independently of antiseptic or Listerian method, tended to lower the mortality of ordinary surgical cases. One cannot but feel that the thanks to the author of the successful completion of 1000 cases should extend far beyond the limits of this room and this Society; they are due to him from the profession and suffering humanity at large."—Mr. WILLETT asked the author if he had in any way modified the after-treatment of his cases, especially as regards the practice of free sweating; for he himself had found in nearly every case a rise of temperature to 102° or even 104° about twelve hours after the operation. This rise was quite ephemeral, the temperature falling below 100° within the next twelve hours; nor did it appear to act injuriously. He had associated this symptom with the practice of placing the patient in a heated room and covering her with hot blankets, with the intention to promote free action of the skin. Out of twenty cases Mr. Willett had had a mortality of three.—Mr. SPENCER WELLS, in reply, said that for several years past he had discarded the practice of extreme overheating. In former days this was carried to a great extent, even to filling the room with steam. He believed Mr. Willett's explanation of the rise of temperature in his cases to be correct; and it was certainly curious that whereas now, in a whole year, he (Mr. Wells) had not had one case with a temperature above 101°, he used frequently to have cases with the temperature reaching 104°, or even 106° and 108°. He thanked the President for his kindly remarks, and said that such an approbation from the Chair was quite sufficient reward for his work.

Dr. GEORGE THIN read a paper "On the Development of a Layer of Elastic Fibres in Duct Cancer of the Breast." The paper gives a summary of the results of an examination into the nature of a layer of elastic substance described by the author in a paper read before the Society last session as surrounding epithelial masses in duct cancer. The layer is analogous to the elastic layer described by Henle as surrounding the lactiferous ducts, is composed of interlacing minute elastic fibres, contains no white fibrous tissue, although a few capillary bloodvessels and leucocytes are found in it, and is separated from the cell-mass by a membrana propria. Its significance is to be found in its association with a new epithelium which takes its origin in duct epithelium, and in the illustration it affords of the retention by a cancerous epithelium of one of the distinctive attributes of the special epithelium from which the morbid growth sprung; and, further, in the unexplained connexion between the development of epithelium and of elastic fibres. A nucleated membrana propria is described as being present around some cell-masses. It is of secondary formation, the nuclei on its surface having the characteristic flat elongated form. An outer and inner line of these nuclei was sometimes detected.

A paper was communicated by Mr. JAMES F. WEST (Birmingham), "On a Second Case of Trephining for Epilepsy." The author called attention to the fact that the patient on whom he had performed the operation two years previously, and whose case was narrated at the Society's meeting of Nov. 25th, 1879, remained in perfect health, and had since been perfectly free from epileptic attacks. He then brought forward the case of a young woman, aged twenty-five, whom he trephined on March 25th, 1880. The operation had proved unsuccessful. Epilepsy began when she was five years old, but was not serious until she was nine, when she sustained a severe cut on the forehead, the cicatrix of which was seen a little to the right of the middle line. The operation was performed at the side of the injury with antiseptic precautions, and was followed by little, if any, constitutional disturbance. No fits occurred for ten days after the operation, but they then recurred, though less frequently than before the operation. She became after a few months dangerous, and in October, 1880, was placed in an asylum.—The PRESIDENT remarked that trephining had fallen into disrepute, because it was generally performed in cases of grave injury, to the effects of which the patients succumbed. The operation was much practised in former days, and where the brain and its membranes were intact the results were not so serious. The case was of interest, as showing that trephining could be had recourse to without much risk, in certain forms of epilepsy.—Mr. HOLMES said the two cases recorded by Mr. West involved two points of interest. Although the author was to be commended for the publication of this second case, yet it was one hardly comparable with the first, where the traumatic nature of the epilepsy was far more evident. For there could be no doubt that trephining was only applicable to those cases of epilepsy traceable to injury. He had seen a few cases of trephining in supposed traumatic epilepsy—one was that of a young man who when a lad had been trephined with temporary relief; the symptoms recurred, but there was not sufficient evidence for a second operation. In Mr. West's first case an apparent cure had resulted from the operation. The other point was as to the effect of the antiseptic dressing. Accepting the principle of perfect cleanliness and drainage, which was the essence of this method, whilst rejecting the theory and details of Listerism, Mr. Holmes had seen great benefit from its application to head injuries. Of this he had lately had a striking example. Two men were thrown out of a cart upon some area railings; one sustained a compound fracture of the thigh, from which he died. The other had a small punctured wound of the skull, only admitting the tip of the little finger, with escape of brain substance. He had also a fracture of the lower jaw; but he was quite free from any symptoms referable to the cerebral injury. Mr. Holmes washed away the loose pieces of brain substance with carbolic lotion, and dressed the wound with ordinary precautions as to cleanliness and drainage. For some time there was protrusion of the brain whenever the patient coughed, but he recovered completely without any symptoms. The case showed how a very severe injury to the skull and brain would get well when treated on the principles of the antiseptic method. He had not seen much mortality after trephining. Of two fatal cases, one was due to meningitis from injury to the dura mater after operation. The case was one of injury to the skull, which was thought to have left depression of the inner table, as in Cline's famous case. The bone was greatly thickened at the seat of injury and adherent to the dura mater. The second case was one under Mr. H. Lee, where the trephine was applied to remove the external table only; here death occurred from inflammation of the diploë. He concurred with Mr. West as to the importance of cleanliness in the treatment of trephine wounds, and believed that when the brain was lacerated, it was important to remove the lacerated portions by washing, as insisted on by Mr. Callender.—Dr. SILVER asked Mr. Holmes if he could give the exact seat of the injury in the case he had cited, as it would be of interest in connexion with the doctrine of localisation of cerebral function.—Mr. HOLMES said the injury was a little above the temporal ridge on the right side, in front of a vertical line from the ear.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Epithelioma of Œsophagus.—Atrophy of Testicle following Traumatic Orchitis.—The Prospects of Valvular Disease of the Heart.

AT the meeting of this Society on the 14th instant, F. J. Gant, Esq., President, in the chair,

Dr. GILBART SMITH exhibited a specimen of Stricture of the Œsophagus, due to Epithelioma, removed from the body of a labourer, aged fifty-eight, who was admitted into the London Hospital, Nov. 27th, under the care of Dr. Andrew Clark. The onset of the man's illness was sudden. He had, seven months previous to his death, experienced a choking sensation on swallowing a piece of meat on one occasion. Subsequently to this solid food always made him choke, and only by repeated efforts was he able to overcome the difficulty, which gradually increased. He continued working until six weeks before his admission. He was then very emaciated; complained of no pain; had a slight hacking cough, with mucous expectoration; had no hæmatemesis; heart-sounds very feeble; liver dulness diminished. Nothing marked about the chest. There was frequent vomiting after efforts to swallow. On Dec. 20th the following note was recorded:—"Can, yesterday and to-day, swallow without vomiting. He feels something 'go' in his throat sometimes, and then swallows better." Bougies were passed several times, and were arrested "half-way." The last attempt to pass one, made on Jan. 4th, was unsuccessful on account of the retching. On auscultation at the back during swallowing the fluid appeared to meet with obstructions at a point corresponding to the upper part of the sternum. Notwithstanding nutritive enemata and the internal exhibition of iodide of potassium and subnitrate of bismuth he rapidly wasted, and died on Feb. 4th, although "about" until the time of his death. The autopsy made by Mr. M'Carthy revealed a hard zonular tumour, surrounding the œsophagus, just above the bifurcation of the trachea. The upper part of the stricture had commenced to ulcerate on the right side. The base of this ulcer was on the point of opening into the trachea. The calibre of the œsophagus was reduced almost to *nil*, but the dilatation of the tube above the stricture was not so great as is often seen. The specimen showed the danger of passing bougies in the later stage of stricture of the œsophagus. In this case there was no history of syphilis or gout.—The PRESIDENT considered that the great distinction to be made in these cases was as to whether the stricture were due to organic disease or to simple spasm. In the latter on getting the patient to swallow hot fluid it was generally at once ejected; in the former it was retained. Scirrhous disease he had never seen above the sternum, but often encephaloid.—Dr. HALL alluded to two cases of marked dysphagia due to syphilis, in which the use of bougies and iodide of potassium had led to complete recovery.

Mr. ROYES BELL showed a case of Atrophy of the Right Testicle due to a severe orchitis following a blow. The patient was nineteen years of age, and came under care for a varicocele on the left side, when it was found that the right testicle and epididymis were reduced to two small fibrous bodies, the vas deferens being apparently normal. Four years and a half ago he had struck the testicle; acute orchitis set in, and he was treated by local applications at a metropolitan hospital for four weeks; the gland then began to waste. On the left side there is a varicocele, and the left testicle is slightly softened. It was not thought prudent to attempt the radical cure of the varicocele, as the opposite testicle was lacking. Mr. Royes Bell referred to the discussion in THE LANCET a few years back, arising out of Mr. H. Smith's advocacy of puncture of the testis in acute orchitis—a procedure much decried on the theoretical ground that it would lead to atrophy of the organ. The present case illustrated a rare sequence of traumatic orchitis, which had been treated in the ordinary way.—Mr. HENRY SMITH considered the case bore out his views with regard to the question. Although he had punctured the testicle in several hundred cases without ever seeing any resulting atrophy, yet in two cases in which he had followed the ordinary plan of treatment recommended in text-books, complete atrophy had taken place. He therefore strongly advocated puncture.—Mr. PEARCE GOULD asked if Mr. Bell punctured in cases of epididymitis as well as in cases of true orchitis, which are exceedingly rare; and whether, if so, it was attended with relief. — Mr. **BELL** said it was his practice to puncture in both, but that relief was better marked in cases of orchitis.

Dr. **MILNER FOTHERGILL** read a paper on the "Prospects of cases of Valvular Disease of the Heart." He pointed out that the well-marked cases, as described in text-books, were generally recognised and appraised correctly. But there were other cases marked by the presence of a murmur when the prospect was very much better. Much misery to patients, and considerable discredit to the profession, were the result of transferring to such cases the prognosis of the most serious forms. Practitioners scarcely ever erred about the grave cases, but they were not always so accurate about the less serious cases. Stokes long ago pointed out that there were cases where the mischief did not progress, or imperceptibly; and Latham differentiated three forms of mitral mischief after endocarditis of varying severity. It was important to recognise the fact that in many cases the injury done is quiescent, like a scar, and the patient is only conscious of something wrong on effort. All light work was not incompatible with length of days. He then related the history of four cases, all well known to him, of mitral disease. 1. A girl, who had a loud mitral murmur at the age of eight. She is now twenty-four, in fair health, as a village schoolmistress. 2. A man whose murmur was first heard in 1867, sometimes ailing, but at work as a blacksmith, only troubled when shoeing very heavy horses. 3. His sister, with disease of two years' standing, last year flooded in labour. She became anæmic, and then some dropsy followed, which quite disappeared under treatment. 4. A man with some mitral disease of twenty-seven years' standing, who had dropsy for the first time last autumn after a short illness. He is now free from any dropsy and feeling well again. Another case of severe mitral disease, lasting thirty-eight years, was cut short by bronchitis last spring. Even aortic regurgitation does not always progress rapidly, and he knew of a number of cases where no perceptible progress had been made in four or five years. Consequently we are not to take a hopeless view of all cases of valvular disease of the heart.—Dr. **DE HAVILLAND HALL** spoke of the life assurance aspect of heart disease, and gave instances in point. Death from bronchitis in valvular disease was directly due to the heart affection, and he agreed with Dr. Fothergill as to the advisability of great caution in prognosis.—Dr. **GILBART SMITH** said the difficulty of arriving at an accurate prognosis was in many cases very great. In one case of præcordial pain a soft bruit came out on exertion and the apex was displaced outwards. In such a case a reservation of opinion for further observation would be construed by the patient as a verdict of "heart disease." In another case, one of aortic regurgitation, apparently not advanced, sudden death occurred from the patient taking a journey contrary to advice. Such cases caused considerable hesitation in forming a prognosis. In life assurance, mitral murmurs, when unaccompanied by dilatation, accentuated pulmonary second sound, or venous engorgement, might readily form a good investment, for the slight risk would be more than compensated by the increased premium.—Dr. **ALTHAUS** thought the views in the paper confirmed by the fact that most of the deaths from heart disease in the Registrar-General's return were set down from sixty to seventy years.—Dr. **BROADBENT** agreed with the views of the author, and considered that heart disease was not necessarily fatal. It was his practice in such cases as those referred to to give a straightforward opinion as to the existence of heart disease, explaining at the same time that sudden death was not to be feared, and that with care a long life might be looked forward to.—Dr. **FOTHERGILL**, in reply, said many of these cases were fit cases for life assurance. He had been in the habit of testing the effect of exertion in evolving murmurs by getting the patient to lift a heavy weight.

EPIDEMIOLOGICAL SOCIETY.

AT the meeting of this Society, held at University College on Feb. 2nd, the President, Sir Joseph Fayrer, in the chair, Surgeon-General C. A. **GORDON** read a paper "On Certain Considerations regarding Cholera and Fever, more especially with reference to India and China." He took as his text weekly reports of health conditions in India, as published in the papers of the day, and from those reports argued that the phenomena of fever, cholera, and small-pox thus presented could not be explained either by the theory of specific poison or by that of contagion. He supported this view by numerous statements, some of which were the result of personal observation, but the greater number were expressions by writers and authorities to whom he referred. In summarising the results at which he thus arrived the following appeared to him the most important—namely, there is reason to believe that although no actual relationship exists between cholera and small-pox, yet the same, or a similar, law applies to the manner of their prevalence as epidemics. Between cholera and malarial fevers a relationship is indicated as existing, alike in respect to causation and phenomena. Both these diseases in India present a general relation to season. Both in India and in England a relationship appears to exist between the type of prevailing fever and locality. Bowel affections generally, in India and elsewhere, present a relation to season and locality, this relation being as defined as that of vegetation to the same circumstances. In endemic fevers intestinal lesions, and those of abdominal glandular tissues, occur as complications in particular cases. Cholera in India occurs under a variety of circumstances, and in different manners, but neither furnish a specific name applied to particular cases as indicating one particular manner of causation. Fevers vary in phenomena and intensity, according to conditions, geographical, climatic, and individual. Among our soldiers in India fevers in the mass and in individual cases are less sthenic in type than they formerly were. Reasons for this circumstance are assigned. Specific poisons are of two categories, as described. Innocuous liquids can, by artificial means, become converted into poisons; hence analogy indicates the likelihood of corresponding changes being effected by means of vital action. But diseased liquids do not necessarily communicate their particular disease when inoculated or swallowed. Certain diseases named by him, which are propagated by infection or contagion, are induced by particular combinations of conditions. Fever in some of its types and forms is of this class; so is cholera. Between these diseases themselves, and with regard to several others occurring epidemically, an affinity is indicated. The expression *malaria* is but another term for climatic influences. The existence of organisms peculiar to malaria has yet to be confirmed. No specific poison is necessary to account for the phenomena of Indian fevers. The theory of specific poison does not explain those in "typhoid" or "enteric" fever. It is opposed as insufficient by a number of authorities. General insanitary conditions predispose to disease; but do they to any one specific disease more than another? It is not established that such is the case. Polluted air induces certain diseases, but not necessarily a specific form of fever. In China, air intensely polluted is compatible with health and activity. The theory of local pollution, if sufficient to account for the occurrence of some epidemics, is altogether insufficient in respect to others. Although contaminated water may induce cholera, the occurrence of that disease is not always thus accounted for. Water induces cholera after that disease has become epidemic; not before. The relation of water supply to cholera in India is not established by recent observations. Very striking instances are adduced where the use of extremely foul water has not resulted in fever, enteric or other. While instances are recorded, particularly in places where cholera is endemic or epidemic, of cases of that disease following the use of contaminated milk; instances are related of infants suckled by women ill of cholera, yet the former not becoming affected by it. Cases said to have been of typhoid fever, due to the use of diseased meat, were subsequently stated to have been cases of trichinosis and sausage poisoning. Although specific typhoid, like several other forms of fever, may be conveyed by milk, this circumstance by itself fails to explain the diffusion of that disease as an epidemic. As a rule, cholera has no relation to age. In India and the tropics generally, the young and the lately arrived suffer more from endemic diseases than the older in age and residence. Infant mortality of Europeans in India is excessive. Individual conditions and habits predispose to particular forms of disease and complications. Climate influences the geographical distribution of disease, and determines its type and incidence. Although cholera has undoubtedly been propagated by means of masses of persons and individuals in numerous instances, there are others equally numerous in which it has not been so. Fevers of particular kinds in India may be propagated by means of infection; but, of the cases investigated by Dr. Gordon, not one was thus accounted for.

In the discussion which followed, Dr. Murray, Dr. Norman Chevers, Dr. Russell, Dr. Thorne, Dr. Thin, and Dr. Collie took part.

HARVEIAN SOCIETY OF LONDON.

A Case of Temporary Hemiplegia after Localised Convulsion.—On Types of Imbecility.

A MEETING of this Society was held on Thursday, February 5th, Henry Power, Esq., F.R.C.S., President, in the chair.

Dr. HUGHLINGS JACKSON read a paper on a case of "Temporary Left Hemiplegia after an Epileptiform Seizure, beginning in the Left Foot," from which the following is an extract:—"I will put the events of the case briefly in stages—1. A man, thirty-five years of age, came into my drawing-room at ten o'clock January 16th, 1881, apparently quite well: he felt well. He had walked from near Temple-bar to my house. 2. In about two minutes he had an epileptiform seizure, the spasm beginning in his left foot; in less than a quarter of an hour the fit was over; there was no defect of consciousness in the seizure. 3. Directly after the fit the left leg was so much paralysed that he could not stand; later on (but after a slighter fit almost limited to that limb), his left arm was weak. I did not test the arm carefully until after the second attack, as I had not finished examining his leg. At any rate, by the time of ending of the second fit (about 10.30) there was hemiplegia, the epileptic hemiplegia of Todd, or, as I think it is better to say, post-epileptiform hemiplegia; the face and tongue were not affected; there was no loss of sensation. 4. He left my house at twelve; by his own account his leg was all right again at ten minutes to two o'clock; possibly it had recovered before; but then only did he try to walk, and was astonished to find that he could. It had recovered to my observation when I visited him at a quarter past four. His arm had, then, also recovered its full movements; he could use it to button, &c.; the exact time of recovery of the arm I did not ascertain. At luncheon (two o'clock) his fork dropped out of his left hand; once he put his left hand on his chop instead of on his fork. Let us say he recovered in a few hours; not wishing to be indefinite, but wishing the reader to take the time as he likes, either from the patient's statement that he recovered in about four hours, or from my observation, that there was recovery in about six: on either account the recovery was prompt. The fact of quick recovery from so much paralysis is very striking, but the case is clinically pointless without noting that the paralysis recovered from was after a convulsion, and there is little point then, unless the particular sort of convulsion be noted. It was an epileptiform convulsion, the spasm beginning locally and unilaterally, and spreading comparatively deliberately; it was a seizure of a class described by Bravais in 1824. It is one of the class depending on disease of the mid-region of the brain. It is one of the seizures whose anatomy and physiology are so much elucidated by the researches of Hitzig and Ferrier into the so-called motor region. The fit my patient had was one of the rarest; it began in the foot. I said that the patient came into my room apparently well. He was not well. He had had three such seizures before the one I witnessed—proof-positive of persisting local disease. In the third one, as in the one I witnessed, there was no loss of consciousness. I got no account of any decided paralysis after the first three seizures; but then he said he was weak, and if this weakness were local he was paralysed. Five minutes after the last of the three he could walk. He had not bitten his tongue in any one of them. The mode of onset is a matter of extreme importance, and, therefore, it may be noted that he referred the sensation at the onset of his seizure, to the outer side of the ball of the big toe. During the paralysis the knee phenomenon on the paralysed side was in great excess, and clonus was easily obtained on that side. These abnormal conditions were not found on the patient's recovery." Dr. Hughlings Jackson then stated the several hypotheses as to the process by which post-epileptiform paralysis results. He adopts the hypothesis of Todd and Alexander Robertson, that there is temporary exhaustion of nerve fibres consequent on the excessive discharge in the paroxysm.—Dr. FERRIER and Dr. BUZZARD spoke.—Dr. HUGHLINGS JACKSON, in reply, said that he attributed the paralysis but little to "running down" of tension of the cells which discharged, but rather to exhaustion of fibres affected by the discharge. There was no evidence of exhaustion, in the sense of general bodily exhaustion; before the fit the man walked well. Dr. Jackson admitted that in cases of persistent cerebral lesions there might occur occasional symptoms from mere general bodily exhaustion, and in illustration mentioned a case of organic brain disease where the patient always spoke badly when he had gone a long time without food. He alluded also to the well known case of Sir Henry Holland, who, when fatigued, lost his German but not his English, regaining his German after rest, food, and wine. But in the case related there was no general exhaustion, and there was a convulsion. The case after the fit differed from a case of ordinary hemiplegia in that, during the prior paroxysm, effects had been produced from the cortex to the muscles convulsed. Dr. Hughlings Jackson believed that some fibres in the lateral column were exhausted, and he believed that the exaggerated knee-jerk and the foot clonus were owing to loss of cerebral influence—to "loss of control."

Dr. FLETCHER BEACH then read a paper "On Types of Imbecility." The author commenced by referring to the different systems of classification of cases of imbecility which have been adopted and brought forward, one of which by experience he had found useful in describing the disease. Cases under this system are classified under the headings of congenital and acquired imbecility, including under the former those occurring at the time, under the latter those supervening after birth. The following classification was the one suggested by the author:—*Congenital Imbecility.*—1, Simple congenital; 2, Microcephalic; 3, Hydrocephalic; 4, Scalphocephalic; 5, Pearly tic; 6, Cretinism (sporadic, endemic). *Acquired Imbecility.*—1, Eclampsic; 2, Epileptic; 3, Hydrocephalic; 4, Paralytic; 5, Inflammatory (*a.* Hypertrophic); 6, Traumatic; 7, Cretinism (endemic). It was shown that under the heading "Simple Congenital Imbecility" are included cases of a very low, and others of a fairly high, type. The cause of microcephalic imbecility was discussed, and the difference between the hydrocephalic and rickety head was pointed out. The cause of scaphocephalic imbecility was said to be obscure. Pearly tic imbeciles were shown to make good progress mentally, but little physically. The characteristics of sporadic and endemic cretinism were usually the absence of a thyroid gland, and generally the presence of fatty tumours in the posterior triangles of the neck. More improvement was stated to take place in cases of acquired than in congenital imbecility, and the reason for this was explained. Eclampsic imbecility was shown to be due to convulsions coming on soon after birth, continuing some years and then ceasing, but so injuring the structure of the brain during their continuance that the patient becomes imbecile. Under the heading "Epileptic Imbecility" are included some cases where with cessation of fits the greatest improvement takes place, and others who go on from bad to worse and finally end in utter dementia. Inflammatory imbecility was said to be due to measles, typhoid fever, and other acute diseases, as a result or complication of which inflammation of the brain and membranes was produced not sufficiently grave to be fatal, but serious enough to cause mental impairment. The reason for placing hypertrophic imbecility in this class was explained, and the difference between hypertrophy of the brain and chronic hydrocephalus was pointed out. Traumatic imbecility was stated to be due to some injury of the brain, hereditary predisposition acting as a predisposing cause in these, as in other, cases where a slight exciting cause seemed scarcely sufficient to produce so grave a result. Cases illustrating the different classes were related, and the paper was accompanied by photographs of patients under the author's care.

Dr. Hughlings Jackson, Dr. Buzzard, Dr. Ferrier, Dr. Mahomed, and the President thanked Dr. Fletcher Beach for his able and interesting paper, and briefly criticised various portions of it. Dr. Beach replied.

OBSTETRICAL SOCIETY OF LONDON.

Deep Depression in the left Frontal Bone.—Modification of Hodge's Pessary.—Extra-uterine Fœtation.—Villous Degeneration of the Endometrium.

AT the annual meeting on Wednesday, Feb. 2nd, 1881, Dr. W. S. Playfair, President, in the chair,

Dr. GODSON exhibited two children, each of which showed a deep Depression in the left Frontal Bone, the result of pressure from the sacral promontory during delivery. One, four days old, was delivered by forceps, the pelvis of the mother being much deformed, and at the time of birth the indentation was so great that the bone appeared to have been fractured. The blade of the forceps encircled the left malar bone, quite clear of the depression, and had not slipped. The second child, seven weeks old, was also delivered by forceps in a rickety pelvis, the sacrum presenting a sharp angle. It appeared to him natural that the head in the first position, endeavouring to rotate into the antero-posterior diameter, should receive the pressure on the left frontal bone, when the sacrum was unduly prominent.—Dr. WILTSHIRE had seen several such cases of depression produced by the promontory of the sacrum, not by the forceps, in connexion with rickety pelvis. Generally the depression did not persist, and it could sometimes be removed by atmospheric exhaustion. He had seen convulsions produced by deep depressions.—Dr. J. WILLIAMS did not see how a depression so situated on the frontal bone could be produced by the promontory of the sacrum.—Dr. FANCOURT BARNES had lately seen a child born with just such a furrow as was seen in one of the children shown by Dr. Godson. The sacrum was projecting, but forceps had not been used.—Dr. CARTER mentioned a case in which the pelvis was contracted in the conjugate diameter; labour was protracted, but the forceps were not put on till the head was in the pelvic cavity. The left parietal bone of the child had a depression large enough to contain the bowl of a dessertspoon. It had no symptoms of pressure on the brain, and in about three weeks' time the bone had almost recovered its normal contour.—The PRESIDENT was inclined to think that the appearance of the depression in the younger child seemed to indicate that it might have been produced by the blade of the forceps, the skin being somewhat abraded.—Dr. GODSON, in reply, said that after the birth of the child he reapplied the forceps over the mark left by it. He was perfectly certain that the instrument was no factor in the causation of the depression.

Dr. GERVIS exhibited a Modification of Hodge's Pessary, in which the sacral end instead of being, as usual, rounded, presented a considerable central depression. The advantages claimed for this were that the tendency of the fundus to roll to one side of the pessary was obviated, and a much steadier pressure on the fundus was maintained. The makers were Messrs. Walters, Palace-road.—The PRESIDENT remarked that one of Thomas's retroflexion pessaries had a similar concavity at the sacral end.—Dr. BARNES said that the pessaries sold as his were not of the form in which he used them. They were made of flexible metal, and he moulded them himself. According to the conditions of each patient he thought the square shape of the lower end of Dr. Gervis's pessary objectionable.

Dr. BURTON showed a specimen of Extra-uterine Fœtation. The patient was thirty-one years old, mother of five children, the youngest of which, seven months old, she was still suckling. The menses had been on from the 17th to the 22nd of January. On the 24th, at 5 P.M., while lounging in an easy chair, she had coitus with her husband. Towards the end of the coitus she slipped forward over the edge of the chair, and immediately felt a sharp pain at the lower part of the abdomen, became faint, vomited twice, and had several actions of the bowels. When she was seen, at 10.30 P.M., she had severe pain at a defined spot two inches from the mesial line. The pulse was scarcely perceptible, extremities cold, and she was evidently sinking rapidly from internal hæmorrhage. She died nine hours after the injury. At the post-mortem examination a large clot of blood was found filling the pelvic cavity and extending some distance upwards towards the umbilicus. The right Fallopian tube about an inch from the uterus was expanded into a cyst about the size of a Barcelona nut, on the upper surface of which was a small opening. The cyst contained a fœtus of six weeks' gestation. The left ovary contained a corpus luteum a quarter of an inch in diameter. The uterus was lined with a smooth decidua. Mr. Burton, by a negative process of reasoning, was led to the diagnosis of ruptured Fallopian tube, but considered it too late when he saw the patient to attempt operative interference.—Dr. WILTSHIRE said that this case was another and an emphatic illustration of the importance of carrying out, where feasible, a practice he had already repeatedly recommended in such cases—viz., the ligature and removal of the burst Fallopian tube.

Dr. MACCALLUM narrated a case of Villous Degeneration of the Endometrium. The patient, aged fifty-one, was admitted into the Montreal General Hospital on Oct. 4th, 1879, for metrorrhagia. Her mother died from melanotic cancer of the hip. After the menopause, which occurred at the age of forty-five, she suffered from leucorrhœa for several years. Metrorrhagia came on three years ago, and had recently become profuse. The uterus was less movable than usual, the sound passed three inches, and caused moderate bleeding. There was a greyish discharge from the vagina, which became offensive in November, and continued so until her death. She suffered severe pain, not constant, but periodic. She went out on Jan. 8th, but was readmitted on May 13th, being now emaciated and cachectic in appearance. The uterus had increased in size. The cervix was dilated with a laminaria tent, and more full dilatation was effected by four tents on June 9th. The whole surface of the endometrium was found to be covered with soft projecting granulations. These were scraped away with a curette, and fuming nitric acid applied. On July 16th dilatation was repeated. After removal of a second tent, symptoms of collapse came on, and she died on July 17th. The uterus was found dilated into a cavity large enough to contain a hen's egg. On the anterior wall was an ulcerated patch as large as a crown. The rest of the uterine wall was thickened, and covered internally with villosities. A teased-out specimen of a villosity showed two elements: (1) Cells, epithelial in character, the majority of the columnar type; (2) a fibrous stroma, made up of irregular spindle-shaped cells. Considerable doubt existed as to whether the disease should be grouped with malignant affections.—Dr. GALABIN thought that, from the character of a teased-out specimen, there could hardly be a doubt that the case was one of the so-called "cylinder epithelioma." It was clear from the history that it was clinically malignant, and distinct from simple forms of villous degeneration. He had met with several cases in which cylinder epithelioma affected the whole internal surface of the body of the uterus uniformly, so that it might appear at first doubtful whether the case was one of malignant disease at all. Such cases might possibly admit of eradication by extirpation of the uterus.

The PRESIDENT then delivered the annual address, which was published in our last issue.

Dr. PRIESTLEY, in eulogistic terms, proposed a vote of thanks to the President. It was seconded by Dr. GERVIS, and carried with acclamation.

MEDICAL OFFICERS OF HEALTH SOCIETY.

AT a meeting of this Society, held at Adam-street, Adelphi, on February 18th, Dr. Bristowe in the chair, Mr. SHIRLEY MURPHY read a paper "On the Duties of Medical Officers of Health in relation to the present epidemic of Small-pox," of which the following is an abstract:—After referring to the fact that medical officers of health are practically deprived of any but indirect influence over the one measure which, above all others, is able to prevent an extension of small-pox, Mr. Murphy stated, that if they could ensure the proper vaccination of every person in their district, small-pox would be altogether unknown to them; but when thought is directed to the number of persons who by birth are constantly added to the unvaccinated population of London, and that these, as a rule, remain unvaccinated for a period of three months, or more, it is at once seen that from this one cause alone there are some thirty thousand persons in the metropolis in the highest degree susceptible to small-pox. When to these are added the remnant who altogether escape vaccination, and the enormous number of those who are badly vaccinated, it is in a crowded city like London, with the constant opportunities afforded for the dissemination of disease by the free intercommunication of people, that small-pox so constantly prevails. This would continue until time gives the Compulsory Vaccination Acts an opportunity of exerting a large influence over the community, and until London more clearly appreciates the fact that vaccination, to be thoroughly effectual, must be properly performed. It was a matter for regret that the enormous protective power of vaccination was not more fully recognised and acted on by medical men. Seeing that vaccination is the one means above all others of preventing small-pox, it is somewhat extraordinary that the officers whose duties relate to the proper performance of this operation should be under the control of the Guardians, instead of the Sanitary Authorities of the metropolis. By the regulations of the Local Government Board the vaccination officer is to give his first attention to localities in which small-pox exists, and to ascertain what children are unprotected by vaccination. No better arrangement could exist if this officer were to make his inquiries from person to person in the infected house, and if his duties had relation not only to those unvaccinated, but also to those who are unprotected against small-pox. Unfortunately, experience shows that this is not likely to be done with that efficiency which is required to prevent this disease from recurring in the household. There is no supervision of the performance of his duties in this respect; he is responsible to his Vaccination Committee alone, and the small fee which encourages him to secure the vaccination of unvaccinated persons is not granted for the same duties in regard to those who need revaccination. Again, although the public vaccinator may attend at houses in which small-pox exists with a view to vaccinating the inmates, he receives payment only for those who have never been vaccinated, and for the revaccination of those who are over twelve years of age, leaving a proportion of children who may not be sufficiently protected against small-pox. The district poor-law medical officer may also vaccinate in these houses, but he is as much limited as the public vaccinator, and is at the disadvantage of not having the same means of keeping up a supply of lymph. To prevent the recurrence of small-pox in houses in which a case has already existed, there should either be no thought of payment by the case; or, if this plan must be maintained, the public vaccinator should be entitled to charge for the revaccination of every person in the house who is not protected against small-pox, whatever his age may be. Good as are the arrangements of the Public Vaccination Department for securing the vaccination of infants as they are born, they cannot be altogether depended upon for preventing the extension of small-pox. The aim of the Vaccination and of the Sanitary Departments is different. It is the duty of the former to vaccinate persons of certain ages—of the latter to prevent small-pox; and for this purpose health officers ought to have at their command the means of immediately vaccinating those who are unprotected. No arrangement which does not permit this operation being performed without loss of time can be regarded as satisfactory, seeing the very great importance which attaches to the vaccination of those exposed to infection within the first few hours after their exposure. One of the evil results of the dissociation of public vaccination from the sanitary authority is that the officers of the latter have thought rather of hospital accommodation and disinfection as the chief weapons for fighting small-pox. The removal of the sick to hospital is not an unmixed good. It is undoubtedly optional to every person to escape from small-pox if he choose, and the time cannot be far distant when the vaccinated will raise objections to paying large sums for the maintenance of hospitals to prevent unvaccinated persons from contracting a disease against which they can so easily protect themselves. Moreover, the effect of providing hospital accommodation is to encourage people not to resort to vaccination, but to trust to other means for safety. However, the question with medical officers of health is immediately less how to teach future generations than to save those amongst whom they live; and knowing that a large proportion of the population at the present time is susceptible to small-pox it is their duty to isolate the sick, while at the same time they use their best endeavours to educate the public in the knowledge that the expense to which they are put is but the price of ignorance. Without entering into the question how far a small-pox hospital is a source of danger to a district in which it is placed, it may be stated that it ought to be able to exist without being such a danger. As the Metropolitan Asylums Board cannot receive small-pox cases to the same extent as they have in previous epidemics are health officers to advise their sanitary authorities to provide the necessary accommodation? If the disease were either typhus or scarlet fever there would be no hesitation upon this point; with regard to small-pox, of course, the facts are very different. But, recollecting that so many persons are still susceptible to small-pox, it is the duty of the health officer to recommend the provision of hospital accommodation until the community at large has decided how far unvaccinated persons are to be treated with special consideration. At the present moment health officers can do much by obtaining the daily visit of the public vaccinator at the vaccination station at a time when all can attend; and if the guardians are unwilling to increase the number of vaccination officers to the extent required, do far better by obtaining from their sanitary authority leave to engage the services of a number of medical students for the purpose of a room-to-room inspection of the infected area. Upon the medical officer of health devolves the whole responsibility of organising the various steps which should be taken to combat this disease. He should visit the houses of the sick, and aid in inspecting the vaccination of the household, while the inspection of the vaccination of school children will also be one of his duties. He should also make it his business to investigate the circumstances under which each person has contracted his disease. Lastly, Mr. Murphy reiterated the statement that medical officers of health should have more directly under their control the power of obtaining the immediate vaccination of persons resident in the house with small-pox patients, and that in future the health officer should trust rather to this course than to the methods upon which he is wont to rely in dealing with other infectious diseases.

In the discussion which followed the President, Dr. Buchanan, Dr. Tripe, Dr. Dudfield, Dr. Corner, and Dr. Gwynn took part.

Reviews and Notices of Books.

Relapse of Typhoid Fever, especially with reference to the Temperature. By J. PEARSON IRVINE, M.D., F.R.C.P. London: J. & A. Churchill. 1880.

IT is with a deep feeling of sadness that we have perused the pages of this book, for they reflect strikingly that steady purpose and unflagging energy combined with a rare talent for critical analysis, which would have made for its author a deserved reputation had his life been spared. No one who takes up the work and carefully follows its argument can fail to admire the extreme care and painstaking which must have been bestowed upon it. It deals with but a small corner of medicine, it is true, yet the author has submitted the nook to most penetrating scrutiny, and cleared it of much that made it dark and obscure. The profession will be the richer for this book, and will the more regret that the bright intellect which produced it will no longer aid them in the search after truth.

The task attempted by Dr. Irvine might at first sight seem to be almost a hopeless one. It was to analyse the pyrexia of the relapses of typhoid fever so minutely as to endeavour to extract some definite laws regarding their onset and duration. Could it be possible that so uncertain and variable a condition as a relapse really followed as definite a course as the primary attack? To this question Dr. Irvine, backed by a number of careful observations, felt himself enabled to give an affirmative answer. He has been able to show that many cases of the disease, when they first come under notice of the medical man, are really relapses following upon a mild and unheeded primary attack; that other cases in which the duration of the fever far exceeds the usual limits without an intermission are cases in which a relapse has, so to speak, occurred intercurrently, while the primary fever was still in force. Again, he shows that relapses are more frequent than is commonly supposed, and that they are often confounded with accidental complications; and the importance of this cannot be gainsaid. In ordinary cases he has found that there is an interval averaging five days between the primary attack and the relapse, an interval during which the temperature is normal or subnormal. This apyrexial interval may, as we have just said, be wanting; it may last only twenty-four hours, or it may be prolonged to ten days; but if a longer interval than this should occur, it is likely that a mild relapse has taken place unobserved, and has been succeeded by a more severe one. The occurrence of one relapse appears indeed to predispose to a second. The average duration of a first relapse is from twenty to twenty-one days, apart from complications, and when two or more relapses occur the later are shorter than the preceding ones, just as the primary attack with a duration of twenty-eight days exceeds the primary relapse. The subject, however, is one of much difficulty, owing to the varying elements introduced by complications and "intercurrent relapses," and the confusion of true relapse with sequelæ. Perhaps the point which stands out most clearly in the research is the determination of the temperature curve of the relapse. The numerous charts, which go so far to enable the reader to follow the author's statements, bring this out in a striking manner. The onset of the relapse is sudden, the temperature reaching its height by the fifth day, and maintaining a high level till the eighth or ninth day, when it falls decidedly, rising, however, afterwards, to decline gradually to the twentieth or twenty-first day, when the relapse comes to an end, having passed through three distinct and well-marked stages. To most of us this must come like a revelation, and it will be well if the statement made on such good grounds should lead to a careful scrutiny of the temperature curves of typhoid fever. Firmly impressed with the truth of this, the author has frequently been able to determine, from a study of the thermometric curve, the existence of a relapse where it was unexpected; and in cases of "ambulating" typhoid, where the relapse is the condition calling for treatment, the knowledge of the course and duration of the pyrexia is of inestimable value.

The foregoing is only a small part of the conclusions arrived at by the author. Some of his statements require to be carefully studied before their full import can be grasped; but his main conclusions are so rational that we have no doubt they will be fully verified by others. Of late the temperature in typhoid fever has been less studied than it should have been. The exceptions to "Wunderlich's law" seemed to be too numerous to justify the conclusions drawn from it by that acute observer. Now, however, we have some explanation of such exceptions, and we have almost formulated for us a "law of relapse." The modern treatment of typhoid does not lend itself very favourably to such studies; for undoubtedly, if it do not prevent relapse, the practice of cold bathing interferes with the natural thermometric curve. But, of course, this fact does not detract from the great merit of this book, one of the most careful and original contributions to the clinical study of disease that has appeared for a long time.

Pseudo-Hypertrophic Muscular Paralysis. By W. R. GOWERS, M.D., F.R.C.P., Assistant-Professor of Clinical Medicine in University College, &c. London: J. and A. Churchill. 1879.

THIS valuable monograph is a reprint, with additions, of an interesting lecture which appeared in our columns in July, 1879, and contains analyses of 44 original cases, which, with others referred to by various authors, make a total of 220. A description of many of the cases is followed by a succinct account of the etiology, symptoms, prognosis, pathology, and treatment of this peculiar disease, so that in this small work of sixty pages we have by far the most complete account of this interesting malady which has appeared in any language, and all clinical physicians must be greatly indebted to Dr. Gowers for such an excellent synopsis of the main features of an affection which, although comparatively rare, is so very striking that it immediately attracts attention. Among the chief points on which Dr. Gowers lays stress are that it is almost always a disease of early life, that it affects boys much more frequently than girls, and that it is usually inherited through the mother. The prognosis is very grave, inasmuch as most of the sufferers die from broncho-pneumonia, and as treatment—cod-liver oil and mechanical exercise being the most important—has but little effect on the progressive nature of the malady. The symptoms are clearly described and explained, and the simultaneous increase of many muscles, especially those of the calf, with decrease in others, such as the sterno-costal portions of the pectorals and the serrati, is shown by numerous drawings. The curvature of the spine in advanced examples is also strikingly illustrated. With regard to the pathology of the disease, the author, after discussing the theories which ascribe it to a primary affection of the spinal cord, the sympathetic, or the "trophic nerves," is of opinion that it is a primary disease of the striated muscular tissue due to a congenital nutritive and formative weakness, and is in this opinion supported by Friedrich. This view is well argued, but we cannot say that we are quite convinced that this is a complete explanation of the strange development of fat and fibrous tissue in the affected muscles. Detailed accounts of future cases will, we think, show that there is something behind the mere muscular changes. A complete bibliographical reference to the cases on record completes a most valuable work.

STEEVENS'S HOSPITAL, DUBLIN.

IN 1878 a coroner's inquest was held at this hospital on a man named Anderson, a member of the constabulary, who had been an inmate, in consequence of serious charges made against the management of the institution. As a result of the evidence given at the inquest, a correspondence took place between Colonel Hillier, the Inspector-General of Constabulary, and the governors, relative to the treatment of constabulary patients in the hospital, and which has now been issued as a Parliamentary paper, on the motion of Mr. Callan, M.P. for the county Louth, that the correspondence in question should be published. Colonel Hillier, in a letter dated September, 1878, drew attention to the system at that time in force which permitted constabulary patients, who were charged 1*s.* 4*d.* daily for their maintenance in hospital, to purchase from an *employé* of the hospital articles of food in addition to the dietary ordered by the medical officers. Further, that the patients in the constabulary ward were left during the night without any nurse being in attendance. He recommended that for the future no post-mortem examinations should be undertaken, except where permission had been obtained from the nearest relative of the deceased. The governors in their reply (October, 1878) acknowledge that the ward attendant had been in the habit of selling food as alleged; that there were nurses hired to go through the wards at night and attend on such patients as required their assistance; and they promised to comply with the recommendation of the inspector-general as regarded post-mortem examinations. As two years elapsed from the date of the inquest to the time the member for Louth obtained the order for the publication of the correspondence above referred to, it is probable that he intends again to draw attention to the management of Steevens's Hospital.

THE Board of Medical Studies of Cambridge University recommend that Mr. W. Hillhouse, B.A., of Trinity, be approved as a University teacher of botany, and Mr. James A. Lister, B.A., of St. John's, be approved as a University teacher of comparative anatomy.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 26, 1881.

IF the Government decide to refer the questions constituting medical reform to a Royal Commission we may reasonably expect them to be dealt with much more thoroughly than they could be if disposed of now. It has always been our contention that time and discussion were not thrown away upon this subject. Accordingly, in 1871, when a Bill dealing mainly with the consolidation of the nineteen examining bodies, ten at least of which were superfluous, was pressed upon the House as a practical settlement of all the evils of our present system, we felt it our duty to maintain that it was better to postpone the whole question than to settle it so. Everything has moved since then but the mind of the corporations, and of the Medical Council, and it has moved too—only backwards. It is now universally admitted (outside of these charmed circles) that the whole examining system is a survival of the unfit and indefensible, not to say the unjust and the absurd.

If Lord SPENCER has come to the conclusion that a Royal Commission is needed to dispose of this subject, we may fairly conclude that he means to deal with it in a way less piecemeal and patchy than has been the case in former attempts at legislation. When the Bill of 1858 passed it gave Imperial importance to institutions that previously had a very limited jurisdiction. The holder of a half diploma of the humblest corporation in any division of the kingdom, before 1858, was empowered only to practise under the more immediate eye of his "Body." Since 1858 each "Body" has given a claim to registration and a licence to practise in all parts of Her Majesty's dominions. All territorial restrictions were broken down, and properly so, by the Act of 1858, and men holding the licences have crossed borders and channels, and gone to the colonies and dependencies, with a claim to be recognised and registered everywhere. Unfortunately with the widened virtue of the licences of the corporations, there has been no corresponding enlargement of their sense of responsibility. Like all corporations, they have aimed at making money and retaining privilege, and the chief conception of reform in their view has been to reconcile the fact of the cessation of their individual importance with the perpetuity and aggrandisement of their individual interests. When it became apparent that there were far too many medical corporations, and that it was a public evil and scandal that examining bodies should have a pecuniary interest in parting with their half diplomas, the remedy which presented itself to us, and to all simple-minded reformers, was to allow the superfluous corporations to die a natural death by withdrawing from them all diploma-granting duties, and further representation at the board of the Medical Council. Very different was the conception of the bodies themselves. They saw they were *de trop;* that individual existence could only be continued by competition, by easy conditions of examination, and they acted accordingly. When the scandal was exposed, as in 1871 and in 1878, they were compelled to give up individual action, and they did it in 1871 with reluctance, and in 1878 with resistance. But—and here is the discreditable feature of *nearly* all the Medical Bills for the cure of numerous and competing boards—under what conditions did they consent or were they compelled to give up individual examinations? Under the conditions that they should all be maintained superfluously in perpetuity. The principle of the Medical Bills of the last two Governments for dealing with the nineteen corporations was to keep on nineteen corporations, and to mulct successive future generations to keep going institutions which ought to be allowed to rest and be thankful. Such a proposal as this can surely not live before a Royal Commission. It could emanate only from a Medical Council that saw it was composed of corporations like unto glass-houses, and only to be saved by holding all together. We shall expect a Royal Commission to see that we want three medical examining boards, to give us three medical examining boards, and not to give us nineteen in another form and with all the present cost and the existing complication of interests.

Similarly with the question of the Medical Council. A Royal Commission could scarcely be content on this subject with the evidence of the Medical Council itself, composed predominantly of gentlemen admirable and eminent in their individual capacity, yet sent to the Council to represent corporations and interests. As we have already said, we think the case against the Council already made out. It is, indeed, made out by simply stating its composition, which includes strongly the bodies which everybody sees, though possibly adapted to the sixteenth, seventeenth, and eighteenth centuries, to be an anachronism now, and which reflect very feebly the working and, after all, the principal part of the medical profession. For it must never be forgotten that the end of Acts of Parliament in medical matters is to provide, not Court physicians and shrewd councillors for Royal Medical Corporations, but educated men for the hard and responsible duties of general practice.

Such, then, in our view, is the shape which the question of a Royal Commission should take, and which we may confidently believe it will take in the view of the Government. A Commisson is not needed for the small reforms which have been embodied in past Government Bills, for getting rid of one superfluous corporation in each division of the kingdom, nor for a proper representation of the general practitioners of the country on the Medical Council. But for a complete view of the question how to put the examining authorities and the controlling authority in medical education into a satisfactory state, just to medical students and to medical practitioners, and beneficial to the public and the State, it is not too large a proposal, and, if wisely and fairly composed, may end in a most salutary reform.

◆

WITHOUT the least wish in the world to quarrel with our friends the druggists, we cannot acquit them of inflicting grievous wrong on the medical profession and the public by what is known as "counter-practice." We make no apology for placing our own grievance foremost, not because it is the greatest, but because it is the key to the whole mystery of mischief which is unquestionably wrought by the practice we condemn. Not content with being a preparer and dispenser of medicines, the druggist must needs prescribe. The explanation of, or excuse for, this enlargement of his functions resolves itself into a contention that in the course of his business the dispenser necessarily picks up a considerable acquaintance with the properties of the drugs he compounds, and that it is, therefore, only natural and commercially inevitable that he should recommend the medicinal substances which form his stock-in-trade according to their value as remedies. We are fully prepared to concede this position, but it affords no ground or cover for "counter-practice." If druggists simply supplied "an aperient" or "a saline" when asked for these medicaments, we could have no reasonable cause of complaint. This, however, is not what takes place. A mother brings her child, or an adult applies personally, not for any particular class of remedy, but describing certain symptoms, and asking for something suitable to the relief of those symptoms! This is a widely and essentially different matter from the supposititious "case" which the druggists set up in their own defence. It is not to the dispenser's knowledge of drugs and their properties the public appeal, but to an assumed power on his part to recognise the nature and significance of certain symptoms, and to select and apply an appropriate remedy. We cannot hesitate to characterise the druggist who responds to this sort of appeal as a *quack* not one whit less offensive to the public interests than the unqualified practitioner who holds himself out as a "Doctor."

Counter-practice of the most objectionable kind is scarcely less common in the shops of fashionable chemists and druggists than in those lower-class establishments which do the largest share of the prescribing for the "lesser" ailments of the community. Anyone, lay person or working practitioner, who will take pains to observe what is going on in the shops he visits may satisfy himself that this is the fact. Mixtures, pills, plasters, lotions, and medicines of all sorts, for internal and external use, are freely prescribed by druggists for the affections of children, for the coughs, "indigestions," "bilious attacks," "sore-throats," and what not, of adults, and if the patient is not injured the legitimate fees of the practitioner are intercepted. We do not say the druggists take the fees, but they prevent medical men from getting them. This may not seem a very important matter, but in the aggregate it is; and look at counter-practice as we may, it is a system of irregular privateering, to which the members of a skilled calling like that of pharmacy should decline to stoop.

One form of counter-practice to which we have an especial objection is really too bad to characterise. We refer to the practice of repeating physicians' prescriptions, or even altering them so as to make them answer for ailments other than those for which they were prescribed. The system of "copying" and entering prescriptions has little purpose except for this subsequent use. While there is any chance of a patient requiring to have a particular prescription again dispensed, he may be confidently trusted to preserve it. When that time has passed the sooner the paper is destroyed the better. If on any future occasion the physician should desire to employ the same combination he is pretty sure to find a memorandum of it in his own book. If he does not find it there nothing is more unlikely than that he will send to the druggist for a copy! In short, the dispenser of a prescription copies it simply to obtain a hold on the patient as a customer, and with a view to reference and repetition at some future time. Such objects are totally opposed to the professional interests of the legitimate practitioner, and it is passing strange that respectable druggists do not see the wrong their system perpetually inflicts. A prescription is not a thing for all time, or for any other time than that for which it is given. To perpetuate it is to incur a risk of injuring the patient, and in any case to wrong the practitioner.

Druggists have no knowledge of anatomy, physiology, medicine, surgery, the signs of health, or the symptoms of diseases. It is therefore preposterous that they should be themselves willing or trusted by the public to prescribe. We do not hesitate to affirm that a notable proportion of the worst cases the physician is required to treat are those in which precious time has been wasted, and positive harm done, by the preliminary endeavours of the "family chemist and druggist" to enable the sick person, or parents, or friends, to do without the "doctor." This, as we have said, is not an evil confined to the poorer neighbourhoods, but common to all. In the better-class localities, it is of course done less openly than in the poorer districts, but it is done everywhere. Setting aside *professional* interests, the consequences are sufficiently serious to the public to render an energetic protest indispensable. Cases of grave enteric disturbance are treated as diarrhœa with "carminative" or "cholera" mixture; cases of laryngitis are dosed with jujubes and gargles, supplemented by poultices and liniments. Commencing fever is plied with "something to throw the patient into a perspiration," and "act gently on the bowels." The pains of acute rheumatism are to be "cured" by embrocations; while rose- and elder-flower-water and sulphate of zinc, nitrate of silver, or even acetate of lead, in solution, are recommended as "eye drops" at the outset of destructive diseases of that most delicate organ. In short, every form of ill that flesh is heir to, if only it assails the patient slowly, is pretty sure to be "treated" by the druggist before competent advice is sought. The public suffer, and the medical profession suffer too, not simply in pocket but in repute, for it is incomparably more difficult to grapple with a disease after it has been subjected to a few days or even hours of ignorant dosing, than to deal with it at once, when the diagnosis is easy, and the indications for a scientific course of treatment are plain.

No measure of medical reform will be satisfactory which does not provide for the suppression of "counter-practice" by druggists. The seller of "patent medicine" is a distributor of sealed packages, which the public may misuse; but the prescribing chemist is a pretender who trades on the inability of the uninitiated to distinguish between a knowledge of drugs and a knowledge of disease. We appeal to the Pharmaceutical Society to deal with this question before it comes under the consideration of the Legislature. It would be a graceful and judicious act on the part of the examining and licensing corporation, which has done much to raise the standard of education among druggists, to take this matter seriously in hand. We repeat that we have no wish to quarrel with the fraternity of dispensers. They form a class of skilled tradesmen with whom the relations of the medical profession must always be close, and as practitioners are able to trust the druggists and give up dispensing for their patients, must needs be closer. At the same time, it cannot be permitted that a Medical Bill should pass through Parliament without some attempt being made to guard professional interests in this matter, and to protect the public. We should be glad if the first move could be made by the Pharmaceutical Society, and with this intent we state the facts candidly, and point plainly to the evils we desire to see remedied. A request so reasonable and urgent must certainly be held to call for compliance.

◆

FROM both a clinical and pathological point of view there is special interest attaching to the small tumours developed in the skin and called Molluscum Contagiosum. Its contagious nature, often denied, has again been apparently incontestably proved by certain well-attested facts; but the demonstration of any element in the peculiar structure of the growths to which its contagious properties could be ascribed has been wanting, and observers have therefore been divided into those who preferred to trust to clinical evidence on the one hand, and those who set most value by the minute anatomy of the growths on the other. Until comparatively recently molluscum contagiosum has been looked upon as a disease starting in and peculiar to sebaceous glands, and certain naked-eye characters lent weight to such a view. But, among others, VIRCHOW in Germany and SANGSTER in England have shown that this is not the case, but that the tumours are developed from epidermic cells principally of the root sheath, and not from glands at all. A short time ago, at the Pathological Society of London, Drs. CROCKER and THIN showed several microscopical preparations exhibiting various steps of the growth. As traced by them—and they agree in all essential facts with the earlier description of SANGSTER,—the little tumours most often start in a special development of the epidermic cells of the inner root sheath of the hair follicles, the hair falls out, and the connected sebaceous glands waste. In the altered and proliferated epidermic cells the molluscous bodies are formed from a gradual coalescence of certain dark granules which appear in the protoplasm of the cells along with clear spaces or vacuoles. These molluscous bodies form a firm plug in the centre, which may perchance fall out, leaving a central duct-like cavity. The tumours commonly seen are developed by the formation and coalescence of several separate nodules, and bud-like sproutings of the growth can be traced. Around the epidermic elements there is evidence of irritation in a small cell infiltration of the connective tissue. In all this there is a good deal to suggest the influence of some foreign substance infecting the skin at different spots, and inoculating neighbouring parts of the epidermis from the original growths, especially as it has been shown that the growths, and particularly those coalescing with the primary ones to form the naked-eye tumours, often start in the upper layers of the rete Malpighii, and that they are not limited to the epidermic cells of one special part. But although the suggestion of an infecting something is obvious enough, neither Dr. CROCKER nor Dr. THIN spoke to having seen it. An Italian observer, Dr. A. ANGELUCCI, states that by staining his preparations in methyl-violet and gentian-blue he has been able to demonstrate a micro-organism which he believes to be the specific cause of the disease, and infective in its nature. Immediately around the molluscous bodies in the centre of the growths he finds small heaps of darkly refractive granules in the protoplasm of the epidermic cells. In support of the view that these granules are really micrococci or spores, he alleges that they stain deeply with methyl-violet, gentian-blue, or hæmatoxylin; that they resist the action of caustic potash, ammonia, and acetic acid; and that they can be seen actively moving in fresh specimens prepared by teasing. If these observations, which are recorded in the *Centralb. f. d. Medicin. Wiss.*, are corroborated, there can be little hesitation in attributing to these micrococci a causative influence. Dr. ANGELUCCI explains the histological appearances by assuming that the organisms induce first a proliferation of epidermic cells, and then subsequently a special degeneration or mummification of these cells, and, as this mummification may overtake the proliferation of the cells, spontaneous cure may take place. The micrococci are found only in the layers of epidermic cells surrounding the molluscous bodies, and not in the outer layers; these possibly may act as a barrier against the spread of the organisms into the connective tissue, or which they may avoid from its not being a suitable nidus for their development. They thus occur just where Dr. THIN describes the occurrence of the fine granules and vacuoles preliminary to the formation of molluscous bodies, and there can be no reasonable doubt that Dr. THIN'S granules and Dr. ANGELUCCI'S micrococci are one and the same. If these statements prove to be correct, they will support the view of those who hold that well-observed clinical facts are more trustworthy than anatomical investigations; they will bring our knowledge of the pathology of molluscum contagiosum into harmony with our clinical experience of it; and, each deriving support from the other, there is the great probability that many of the disputed points about this strange affection will be permanently cleared up.

◆

A DEPUTATION of inhabitants of Fulham, Chelsea, and Kensington, accompanied by Mr. FIRTH, M.P., was received by the Metropolitan Asylums Board at their meeting on the 19th inst., and had the opportunity of setting forth certain grievances as to the Fulham Small-pox Hospital. The reception the statements of the deputation met with from the Board was characteristic of the attitude that body has taken up from the beginning in regard to the asserted harmfulness of these hospitals to residents in the immediate vicinity—that is to say, an attitude of determined know-nothingism, and a demonstrative exhibition of injured innocence, that, because they had done their work well in one direction, they were not credited with having done it well in all directions. The Chairman actually deprecated the statements of the deputation as premature regarding the influence of the hospital in promoting small-pox in its neighbourhood. An inquiry, he observed, was now being made into this allegation by the Local Government Board, and the least to be expected was that the residents in Fulham, Chelsea, and Kensington should suspend their judgment until the inquiry was completed and its results reported. Dr. BREWER had evidently lost sight for the moment of the good old adage, "What is sauce for the goose is sauce also for the gander." For, clearly, if it were desirable that judgment should be suspended on the fact of the small-pox hospital tending to increase in some way or other the prevalence of small-pox in its neighbourhood, it was much more desirable that the Metropolitan Asylums Board—nay, morally incumbent upon them—not to add to the accommodation for patients in the hospital until the official inquiry had been brought to an end. Nevertheless, the Board persists in its intention to increase the number of beds for small-pox cases at Fulham, although the Local Government Board deems the report of extension of the disease from or in connexion with the hospital so serious as to call for special investigation. And notwithstanding the gravity of this report, the Local Government Board has actually assented to the increase of beds proposed by the Metropolitan Asylums Board! But a member of that Board, following the chairman, declined to concede to the deputation even a probability in their statements. He took issue at once with them, characterised the movement represented by them as got up for the purpose of hampering the Asylums Board in performing its difficult public duty, and did not hesitate to aver that neither at Fulham nor at Homerton was there the slightest foundation in fact (nor had there been at Hampstead, Stockwell, or Deptford) for the assertion that the small-pox hospital had been a source of small-pox among the houses in its vicinity. The audacity of this statement would have been sublime if it had not simply been an example of the parochialism of the Board—of the oracularity of the parish beadle; for it must be observed that the Board generally were disposed to concur with this speaker, and the denial merely meant that it "is none of our business to know what happens in the next parish, so we shut our eyes to what occurs beyond the hospital walls." The contradiction of the deputation by this speaker may be measured in some degree by the events which have recently taken place at Homerton, and which cannot have been unknown to the Asylums Board.

Not long ago we had occasion to take exception to certain general statements made by Dr. TRIPE as to the occurrence of small-pox in the vicinity of the Homerton Small-pox Hospital. The data on which these statements were based were withheld at the time, but they have now been submitted to the Hackney Vestry, and will presently be published in detail. So far as we have had the opportunity of considering them, they appear fully to support Dr. TRIPE'S statement as to a greater prevalence of small-pox in the vicinity of the hospital. Dr. BRIDGES, however, has been holding inquiry as to this matter for the Local Government Board, and we shall content ourselves with this general statement of our conclusion as to the fact of greater prevalence until we are able to compare Dr. TRIPE'S data with those collected by Dr. BRIDGES. But Dr. TRIPE has not contented himself with attempting to prove this greater prevalence, but endeavours to show how it happens that the prevalence in the vicinity of the hospital has come about. His views have been accepted by the Hackney Sanitary Committee, and, as made known in the *Hackney Gazette*, certainly constitute one of the most formidable denouncements of a public body, or, rather, of two public bodies — the Metropolitan Asylums Board and the Local Government Board—for ignorant and careless performance of a serious public duty that we remember. The statements of Dr. TRIPE and the Hackney Sanitary Committee go to show that the approaches to the small-pox hospital are such, the arrangements for the reception of patients at the gates, the mode of intercourse of the hospital tradesmen with the hospital, and the position of certain parts of the hospital to neighbouring houses, *that extension of small-pox contagion from the hospital itself, or from patients in transit thereto, to people living in the vicinity of the hospital, is a necessity.*

This is pretty much the case of the inhabitants of Fulham and the other districts neighbouring to the hospital there. Similar negligences, it is well known, have been averred of the Hampstead, Deptford, and Stockwell hospitals. In fact, it is now, we fear, becoming apparent that while the Metropolitan Asylums Board hospitals have been advantageous as means of isolation of small-pox to the metropolis at large, they have been distinctly and, we may add, needlessly mischievous to the localities in which they have been placed, and this, probably, owing to an unjustifiable negligence in management, the responsibility for which must be divided between the Asylums Board and the Local Government Board.

The sort of talk which took place among members of the Asylums Board on the 19th inst., when the Fulham deputation was received, explains much as to the failure of that body in one of its most important duties as regards its small-pox hospitals; the failure of the Local Government Board is equally due to its persistent dealing with the public health administration of the metropolis in respect to hospitals as if it were a matter of poor-law administration only. It might be anticipated that accuracy of statement could at least be looked for from both Boards, or at least not misleading statements. But it would now appear we are not to have even this small offset against their blundering. A member of the Asylums Board, speaking for his body, we must assume, informs the public that the Board is "simply" making increased provision for the accommodation of nurses at Fulham; and the President of the Local Government Board adopts pretty much the same tone in respect to the same subject, in his reply declining to receive a deputation from Fulham. The ordinary reader would interpret both statements as signifying that the number of beds for the reception of small-pox patients in that hospital was not to be increased; whereas the new accommodation to be provided for nurses is to be made in order to set free portions of the building—containing some sixty beds, we believe—now occupied by the nurses for small-pox cases!

THE Bishop of Manchester, whose utterances are listened to with respect by the vast majority of his countrymen, pleaded the cause of hospitals last Sunday in a sermon at St. Ann's Church, Manchester, Dr. Fraser said:—"Like all human institutions, hospitals had their advantages and disadvantages; but he ventured to think they had as few disadvantages as any human institution could have. He knew something of the working of the hospitals in that locality, and it seemed to him they were administered with economy and prudence, and yet with a liberal generosity which enabled them to meet all the necessities of the large and closely packed population of Manchester and Salford. Given these things, he knew of no institutions which appealed more directly to the finest feelings which God had implanted in the breast of man. In that triple galaxy of graces—faith, hope, and charity—faith was the root and fair charity the flower."

Annotations.

"Ne quid nimis."

THE UNIVERSITY OF CAMBRIDGE AND THE GENERAL MEDICAL COUNCIL.

A SHARP rebuke from a very unlikely quarter has come to the General Medical Council. Our readers will remember that the General Medical Council last year "recommended" important changes in the preliminary examination of students, though only the year before, and indeed in almost every other year before of its history, it had touched this subject. The Board of Medical Studies of the University of Cambridge, having the latest "Recommendations" of the General Medical Council under consideration, and having Professor Paget, an ex-president of the General Medical Council, in the chair, has somewhat sharply retorted on the Medical Council. The report agreed on by the Medical Board complains that if these "Recommendations" are to have force—which by the way they have not—none of the examinations in Cambridge, nor any one of the several examinations conducted elsewhere by the University (such as the Local Examinations, the Higher Local Examinations, and the Oxford and Cambridge Schools Board Examinations), will fulfil the conditions of the Council. The report complains very naturally that while the Council is always arguing in favour of leaving preliminary examinations to the Universities and other "National Educational Bodies," it is passing "Recommendations" that invalidate the examinations of the Universities. This is very severe criticism from a University Board presided over by an ex-president of the Medical Council—a Council at which Oxford is doubly, and Cambridge well, represented. Professor Paget must have a little pity on the Council. It is paralysed and discredited, in present circumstances, as a Council of Medical Education, and only falls back on the subject of Preliminary Education as an easy and pleasant way of occupying July days. It knows, too, that the Universities will take care of themselves, and not rashly adopt "Recommendations" that cost so much money and so much of the Council's time.

TUBERCULAR DISEASE IN JOINTS.

THE repetitions of history are often witnessed in scientific investigations and beliefs, and the contention that Mr. Croft sought to maintain at the last meeting of the Pathological Society is by no means a new one, although he exhibited what he considers to be new and important evidence in its support. Many years ago it was supposed that the part that tubercle played in chronic articular diseases was very important, as may be seen by referring to an early edition of Dr. Wilks' Pathology. More recently other and contradictory views have been in the ascendant, and Mr. Croft asks that surgeons and pathologists should revert to the opinions held a generation back. In this course he is supported by several German authorities and by Billroth, who until quite recently denied that chronic diseases of joints are essentially tubercular in origin or nature. These alternations in the opinion of authorities within a few years only, and the marked discrepancy now existing between the views of the most prominent English and German surgeons, suggest that the question must be largely a matter of words and not of facts. The disease itself cannot have changed, nor can it be so very different in the several European countries as to lead us to suppose that such discrepancies of opinion are to be explained by differences in the cases examined. The question has to be studied from both a clinical and pathological point of view. As regards the former, it is noteworthy that Mr. Croft brought forward no new facts to support his contention, nor did he advance any arguments with which surgeons were not familiar when they abandoned the view he now seeks to re-establish. And it is also a striking fact that while he spoke of these "tubercular" cases as being characterised by a very tedious course, Mr. Macnamara, who alone of all the subsequent speakers supported him, said that in his experience they were to be recognised by continued high temperature—an opposite condition. It must be admitted, then, that clinically these cases are not to be clearly recognised. And when we find that the cases reported to the Society were all that have been examined in this investigation, we are still further led to the conclusion that if Mr. Croft proves his point, he will not have established a special class of tubercular disease of joints, but have shown that chronic arthritic disease is generally, or perhaps always, tubercular. From a pathological point of view the question presents considerable interest, and there are several views which may be taken as explaining the facts. If the arbitrary definition of tubercle given by Mr. Croft—and we presume sanctioned by Dr. Greenfield—be accepted as clearly distinguishing a special and specific structure to which we are to give the name of tubercle, the specimens exhibited decide at least the one point that such growths are found in chronically diseased joints. The first great histological question is whether this particular arrangement of tissues be specific or only one form of lowly and slowly organised inflammatory material. This question can be answered by facts in relation to other organs and tissues, and while there is such a wide divergence of opinion as to the true meaning of the histological changes in pulmonary phthisis, where this problem has been so often and so long worked at, it will be vain to expect a ready acceptance of Mr. Croft's views on the corresponding processes in joints. It is difficult to realise a true primary growth of tubercles in the structures of one joint alone, but obviously there is little value in mere *à priori* arguments. The subject is one of great practical importance, and while we cannot now speak in more detail on it, we must draw attention to the fact, that if certain chronically diseased joints are in their essence tubercular, and if that tubercle be incapable of organisation, it is evident that removal of such joints at the earliest date that a diagnosis can be made is the proper course of treatment. In such cases delay holds out no hope, but exposes the patient to systemic tubercular infection. Does the records of clinical surgery sanction this?

INSURANCE IN FRIENDLY SOCIETIES.

THE last Report of the Registrar of Friendly Societies, which has recently been published, relates to the year 1879, and contains but meagre reference to that important feature of Friendly Societies, their insurance operations. One of the obligations conferred on societies by the Act of 1875 is that which insists upon the production of a registrar's certificate previous to payment of money on the death of a member. It would at first sight appear that this provision of the Act would have been welcomed by the Societies as affording them protection from fraud. This, however, appears not to have been the case, as the Societies do not all view in a favourable light the restriction which is thus placed upon the over-insurance of infants. Very little reference is made in the report for 1879 to the subject of infant insurance, and this is of an unsatisfactory nature. It is reported that the Chief Registrar has learned through a registrar of births and deaths in Lancashire, that the provisions of the Act bearing upon the insurance of children are "still systematically evaded by certain societies, which profess to pay, as gratuitous, sums in excess of the legal limits." It is stated that the Chief Registrar awaits more precise details before taking further steps in the matter. Prosecution for infringement of the clauses governing infant mortality should be encouraged as far as possible, and penalties should be strictly enforced, as the evasion of the clause in question is a direct incentive to infanticide. It is much to be regretted that the Registrar of Friendly Societies does not furnish in his report statistics of infant insurance, and of the mortality among those insured.

THE NAVY ESTIMATES.

THE Navy Estimates are presented to Parliament in a form which makes it very difficult, if not impossible, to ascertain the cost of the medical establishments and services. No summary is given in them of the number of medical officers, and of their pay and allowances, but this information must be collated from the details given under the explanatory statement of the different votes. Again, as regards Medicines and Medical Stores, &c., although there is a vote under that heading, so many things are included under "&c.", as to render the title misleading. Instead, therefore, of commenting upon the amounts to be voted under the two general headings of "Medical Establishments at Home and Abroad," and "Medicines and Medical Stores," we shall bring to the notice of our readers some of the more important items gathered from a careful examination of the estimates. As regards the *personnel* of the Department, the numbers provided for are 1 Director-General, 3 Inspectors-General, 9 Deputy Inspectors-General, 75 Fleet Surgeons, 107 Staff Surgeons, and 167 Surgeons, making a total of 362 officers. No mention is made of any new grade, corresponding with that of brigade-surgeon in the army. Nor is there any indication of the number of candidates who will be required to fill up vacancies in the service. A sum of £1485 is taken for "Instruction at Army Medical School, Netley," instead of £2185 as last year, and it is stated in a note that "a reduced amount only has been provided for this service, as arrangements are in progress under which the instruction of naval medical officers will in future be conducted at Haslar Hospital." This justifies the meaning we attached to Mr. Trevelyan's statement in the House of Commons, that "successful candidates will receive full pay as surgeons from the moment of entering the service." (THE LANCET of Feb. 12th.) If the arrangements referred to in the note resemble those which were in force before the naval candidates were sent to Netley, we can only express our deep regret that the Admiralty should have decided to take so retrograde a step, and one which cannot fail to act injuriously upon the service. They may thus effect a saving of money, but it will be at the expense of what is of far more value—health and efficiency.

The sum estimated for the pay and allowances of the 362 officers amounts in round numbers to £133,500, being above that taken in the preceding year. The excess does not arise from any increase in the number of officers, but, we presume, from the addition to the pay and allowances intended to be granted by the promised Warrant, and for which a sum of £6560 appears under the head of "improved pay to medical officers." As we have already stated, the manner in which the vote for medicines and medical stores, &c., is taken prevents our estimating the amount really required under these two heads.

We are glad to see that sanitary improvements are at last receiving some attention from the Admiralty. Thus, for the naval yard at Portsmouth £600 appear under this head, and for the victualling establishment at Gosport £500. At Haslar it is proposed to spend £1500 on sanitary improvements in hospital buildings, and £3000 on new sewers. The events of the past year can only make us regret the long delay which has occurred in undertaking works of such importance. At Plymouth £400 are to be appropriated to improvements in drainage and water-supply at the hospital, and at the Marine Barracks, Forton, £1400 are put down sanitary improvements. We regret to observe that no similar grants are asked for any of our naval establishments abroad, although we have strong reason to believe that some at least of them greatly require it. We can only hope that the beginning thus made may be continued from year to year until all recognised causes of preventable disease in these establishments have been removed.

COLLEGE OF PHYSICIANS OF IRELAND.

IN a recent number (p. 186) we referred to the fever certificates required from candidates for the licence in medicine of this College, a regulation which came into operation on the 1st January last, and to which was attributed in a great measure the great falling off in the number of candidates last January as compared with the two preceding months. As this regulation caused considerable inconvenience, the College, by a resolution dated the 11th February, have provided that the by-law as to fever cases shall not be compulsory in the case of students who had commenced their necessary hospital attendances prior to October, 1879. Candidates who commenced their hospital studies between September, 1876, and October, 1879, will, however, be required to furnish evidence either of having, during nine months of their hospital attendances, studied in a hospital containing fever wards, or of having conformed with the by-law referring to fever wards.

SUPRA-PUBIC CYSTOTOMY.

THERE will always be considerable interest attaching to this operation, for in some obvious ways it is marked out as the best means of opening the bladder for the removal of foreign bodies. But the two dangers of wounding the peritoneum and of urinary infiltration have caused its abandonment in general practice, although for the removal of very large stones it is still sometimes employed. Petersen, in the *Arch. für Klin. Chir.*, has recently drawn attention to plans by which he hopes both of these dangers may be minimised, and the operation brought into more general use. He supports Braune's observation, that if, after the bladder is distended, the rectum is also distended, the bladder is so pushed up and forwards that the peritoneum on the apex of that viscus looks upwards rather than forwards; and in two cases thus operated upon the serous membrane was not even seen, while in two others it was easily pushed up and kept out of the way of injury. To prevent urinary infiltration he has practised suturing the incision in the bladder with catgut to get union by primary adhesion. If this is attempted the operation must be conducted with special precautions; the incision in the bladder must be free, and no dilatation of the wound practised either in introducing the forceps or removing the calculus; for all dilatation means greater or less bruising of the edges of the wound, which will entirely prevent union by first intention. We are not surprised therefore to read that in his last case Petersen was not successful in procuring this favourable healing of the wound. Stitching up wounds in the bladder with catgut is not a novel procedure, and Mr. Heath raised the subject for discussion at the Clinical Society a few years ago in connexion with a case of rupture of the peritoneal surface of the bladder, in which he had followed out this practice. The case is not strictly analogous to that we are noticing, but near enough for rough comparison. Petersen formulates the conditions suitable for the "high operation": (1) large hard stones; (2) encapsuled stone or stones lodged in saccules behind the prostate; (3) hypertrophied prostate; (4) hæmorrhoids; (5) very fat people; (6) tumours of the bladder; and (7) impermeable stricture where it is desired to pass a fine catheter from the bladder along the ureter.

THE ARMY MEDICAL DEPARTMENT.

WE are glad to learn that Mr. Childers has decided to retain Sir W. Muir as head of the Army Medical Department for another year. It would have been a very serious loss to the public service had he been removed before the system, which it fell to his lot to introduce, and which has proved to be so successful on service, was firmly established abroad as well as at home. We understand it is now being brought into working order in India under the able superintendence of Surgeon-General Crawford. While this change is in progress and many questions connected with the future of the medical service in India are under the consideration of the authorities, it is of the utmost importance that the Secretary of State for War should have, as his responsible adviser, an officer so thoroughly conversant with the details of the service, and of such decided administrative ability, as Sir W. Muir, to whom to refer in all questions of doubt or difficulty.

THE VESSELS OF THE RETINA.

PROFESSOR HIS, in the third part of his *Archiv* for 1880, gives an interesting description of his observations upon the distribution of the vessels in the retina of man and some animals. He makes this communication *à propos* of a paper by Dr. Hesse, who has demonstrated the existence in the retina of the rat of an internal arterial and an external venous layer of capillaries. Professor His depicts the arteria centralis in man as running in the nervous fibrous layer, and giving off from either side lateral capillary branches, which he names the arteriæ afferentes. These leave the main trunk almost at right angles. After a short course they divide and subdivide dichotomously, and form a tolerably distinct network of arterial capillaries, the individual vessels passing in and out through the spaces of the inner granular layer, where they form the deeper-lying or more external venous plexus. These, again, transmit the blood they contain into the venæ efferentes. The arteria centralis retinæ possesses a muscular tunic whilst it is still embedded in the optic nerve; but this coat becomes thinner as the artery approximates the lamina cribrosa, and loses itself after the artery has traversed that lamina. In the retina itself the arterial branches are surrounded by a tunica adventitia, which gradually becomes thinner. There are no horizontally running capillaries in the molecular layer. All the vessels here have a radiating direction. Another point which he believes he has made out, though he is not quite certain, is that the portion of the optic nerve which is situated distally to the lamina cribrosa is provided with a very close network of large capillaries.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE annual meeting of this Society for the election of officers and other members of the Council for the ensuing year, to receive the auditors' report and the report of the Council, will be held on Tuesday next, March 1st, at 8 P.M. The following nominations to vacant offices have been made by the Council:—President: Dr. A. W. Barclay. Vice-Presidents: Dr. S. O. Habershon, Mr. T. Holmes, and Mr. Spencer Wells. Treasurer: Dr. C. B. Radcliffe. Secretary: Mr. Berkeley Hill. Librarian: Dr. E. H. Sieveking. Other members of Council: Drs. Jas. Andrew, W. Cholmeley, Sydney Ringer, Reginald Southey, and Mr. J. Langton. Dr. Barclay, who has been nominated to the Presidency, in succession to Mr. Erichsen, was elected a Fellow of the Society in 1847.

THE ACCIDENT TO THE PREMIER.

MR. GLADSTONE, as our readers will have learned from the daily press, slipped on the snow and fell when entering the garden in the rear of his official residence in Downing-street on Wednesday evening. The right honourable gentleman received a severe blow on the back of his head. We are happy to learn, on inquiry of the medical gentlemen in attendance, Dr. Andrew Clark and Sir James Paget, that the Prime Minister has not sustained any serious injury. The latest news, as we go to press, is that Mr. Gladstone has slept, and is progressing satisfactorily.

THE DESTRUCTION OF TRICHINÆ.

IT is commonly believed that ordinary cooking will destroy trichinæ and render infested meat innocuous. Without doubt, as has been stated in the daily press, "the encapsuled parasites cannot survive a certain elevation of temperature, and death renders them harmless.' Is it, however, correct to say that a "complete means of protection is furnished by the heat incidental to cookery"? Considerable doubt is thrown on this statement by M. Vacher of Paris, whose authority is of considerable weight. He affirms that the protection given by cooking is quite illusory, and that in the thorough cooking of an ordinary joint of meat the temperature in the centre is not sufficient to ensure the destruction of the parasite. He took a leg of pork of moderate size and boiled it thoroughly. A thermometer placed within it at a depth of two inches and a half, registered after half an hour's boiling 86° F., after boiling for an hour 118°, after an hour and a half 149°, and after two hours and a half, when the joint was thoroughly cooked, 165°. This temperature M. Vacher maintains is insufficient, and we must remember that at the centre, which is still further from the surface than the bulb of the thermometer was placed, the temperature would not be so high. "Trichinæ would escape almost entirely the action of boiling water" in cooking. M. Vacher's note was communicated to the Chamber of Deputies, and no doubt has influenced the decision of the French Government to prohibit entirely the importation of American pork.

AT a meeting of the Westminster Liberal Union on the 19th inst., held for the purpose of considering the question of hospital reform, a memorial to the Home Secretary was agreed to, praying the right honourable gentleman to appoint a Royal Commission to inquire into—"1. The existing hospital accommodation of London. 2. Its revenues from all sources, and its expenditure. 3. What improvements experience may suggest as practicable in association with the present Poor-law administration, or a new central authority. 4. The welding of the whole hospital accommodation of London into one great administrative system, adequate to the possible wants of a population as large again as that in our midst, so that the inefficiencies of to-day and the necessary development may be adequately controlled and maintained in the future."

THE Senate of the Royal University of Ireland last week had under consideration the scheme of organisation, arrangement of examinations, provision for professorships, exhibitions, and proposal to erect suitable buildings, &c., presented by the Committee appointed for the purpose. The report was placed before the Senate on the 18th, and on the 19th inst. revision and ratification took place. The scheme will be submitted to Earl Cowper for his approval, and the Government may shortly be expected to declare their views and intimate the amount of funds they intend to devote to the new university.

The Local Government Board has declined to receive a deputation representing inhabitants of Fulham, &c., respecting the small-pox hospital there, on the ground that as the hospital exists, and is managed under an Act of Parliament, of which both the Local Government Board and the Metropolitan Asylums Board are but the agents in carrying into operation, no good would arise from an interview with the deputation. In other words, we presume this means that the Legislature is the author of the evils complained of. But who first moved the Legislature to act? and upon whose representations did the Legislature act? The active agency in these matters was the Poor-law Board, which the Local Government Board succeeds and represents. The question is not to be allowed to rest. We understand a public meeting will be held this day (Saturday) at the Town-hall, Kensington.

We learn that within the past few months instructions have been issued by which the expenditure in connexion with post-mortem examinations in Glasgow will be considerably reduced, and that the number of such examinations will also be much less than formerly. Till recently post-mortem examinations in cases of persons dying suddenly were very numerous, but orders have been given that they are to take place only in special cases where there may be circumstances of such a peculiar nature as to call for an after-death examination. This change does not emanate from the authorities at Glasgow, but is due to instructions from the Government department to economise. This can scarcely be regarded as a wise economy.

We have repeatedly pointed out the necessity for a perfect system of ventilation in connexion with Turkish baths. The Hammam in Jermyn-street has long stood almost, if not quite, above reproach in this matter. It is, however, with great satisfaction we find that the directors have secured additional land in the rear of their present premises, and that they contemplate enlarging the capacity of the bathrooms as a whole by something like six thousand cubic feet. It is, we believe, intended to construct new hot rooms with radiating stoves and improved ventilation. The scale of charges for medical men is reduced, so that members of the profession generally will now be able to test the efficiency of the Hammam for themselves.

The Education Committee of the Council of the Royal College of Surgeons in Ireland have completed their report upon the proposed Scheme of Education and Examination for candidates for the licence in Surgery. It has been received by the Council and will be discussed in Committee. At present we do not wish to go minutely into the various suggestions made, but we may remark that the report is one which is most revolutionary in its character; and which may be expected to be met with strenuous opposition.

We regret to record the death of the Honourable George Charles Grantley Fitzhardinge Berkeley, which occurred at Lanfleet, Poole, on the 23rd inst. Mr. Grantley Berkeley was well known for, among other amiable traits of character, his love of the lower animals, and particularly dogs. In relation to the subject of rabies and hydrophobia, he has for many years been recognised as a prominent contributor to the public and special journals.

Surgeon-Major Alfred Sanderson, M.D., Madras Medical Service, has been appointed by H. M.'s Secretary of State for India, member of the Indian Medical Board, India Office, in place of Surgeon-Major Palmer, who has retired.

We have received a communication to the effect that Dr. Chadwick, late of Leeds, has been paid the compliment of being nominated to the Council of the Royal College of Physicians of London. We regret, however, to learn that the state of his health will not permit of his accepting the honour. This is the first time, we believe, in the history of the College that such a compliment has been paid to an eminent provincial physician.

We regret to have to record the death of another distinguished member of our profession in the Scottish capital. Dr. Peter David Handyside, F.R.S.E., Examiner and Teacher of Anatomy at the College of Surgeons, Edinburgh, expired on the 21st inst., at his residence in Lansdowne-crescent.

The proposed testimonial to Mr. G. D. Pollock is, it is announced, to take the form of a Scholarship in connexion with the Medical School of St. George's Hospital. The treasurer is Mr. Timothy Holmes, to whom subscriptions may be forwarded.

Messrs. W. H. Beynon & Co. have produced an admirable portrait of Sir John Lubbock. The likeness is excellent, and as a good specimen of the lithographic art the picture will be much appreciated.

John Housley, M.D. St. And., M.R.C.S. Eng., has been elected Coroner for East Retford and District without opposition.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORT OF MEDICAL INSPECTOR OF THE LOCAL GOVERNMENT BOARD.

Shadwell (*Yorkshire*).—We have frequently had to deal with the subject of new buildings and with the anomalous action of the Legislature in regard to them sanitarily—to wit, that, while careful after a fashion to provide for the abatement of nuisances from structural defects in buildings after they have been committed, it has been pre-eminently careless in providing that new buildings shall not be erected so as to repeat the conditions under which nuisance arises. Not long ago we expressed the opinion that while the Legislature betrayed anxiety for the removal of existing nuisances, it was questionable whether, from the want of regulation of new buildings, the conditions under which the greater number of nuisances occurred were not supplied as fast as the older ones were removed. The Legislature was, in fact, engaged in the ingenious game of endeavouring to diminish one set of evils by cutting off at one end while adding at the other. Matters are perhaps a little better now in urban districts which have adopted building by-laws, but not so much better that our sanitary policy in this matter can be looked upon with gratification. This report on Shadwell, from the pen of Mr. John Spears, is a capital illustration of the anomalous nature of legislation on the subject to which we refer. Shadwell is a beautifully situated village in the neighbourhood of Leeds, and partly through the neglect of the sanitary authority, partly from want of by-laws regulating building operations, it has been given up as a prey to speculative builders. The consequence is that in and about the village there have sprung up a number of new houses, some, we presume, styled "villas," which appear to set at nought almost every principle by which it is sought to make a building wholesome to live in. The builders seem to have had in view the ruin of life insurance societies by these ingenious arrangements for destroying the health of the occupiers. But then the buildings are erected, and there they must remain, without the possibility of remedying, thoroughly, the sanitary evils attaching to them, an incessant trouble to the sanitary authority, and a standing scandal to legislative procedures, which are careful to remedy a completed evil, but are indifferent to the prevention of that evil occurring. Mr. Spear's report is of much interest.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Salford.—This report is for the year 1879, and not for 1880. Indeed the report is dated October, 1880. As previous reports of Dr. Tatham, it is so elaborate that we cannot affect surprise that it should appear at so late a date, and that we should receive the report for one year when the report for the next year is, so to speak, due. But the value of reports thus carefully prepared more than compensates for the delay in receiving them. The present report confirms the judgment Dr. Tatham had expressed on two previous occasions of a steady improvement in the sanitary condition, and a marked decline in the death-rate since 1864. The average annual death-rate in the decenniad 1864–73 was equal to 28·0 per 1000 persons living. In the five years 1874–78 it was 27·0 per 1000, and in the year 1879 it did not exceed 24·9. There is evidently still much to be done in Salford before its sanitary administration can be spoken of as so advanced as becomes an important Corporation, and it is with some surprise that we learn that the borough is still so very backward in its arrangements respecting excrement removal and disposal. One of the most interesting parts of the report refers to the use made of the borough hospital for infectious diseases. In the arrangement of this report, Dr. Tatham has adopted the Local Government Board's suggestion as to form of reporting, with considerable advantage to the reader. A very well devised diagram illustrates the diarrhœa mortality and meteorology of the borough in 1879; but we are promised a fuller consideration of the subject of infantile diarrhœa in Dr. Tatham's next report.

Torquay.—Mr. Karkeek is dissatisfied with the facts he has to report in regard to Torquay in 1880, but it is that healthy sort of dissatisfaction which is not content unless it turns what is unsatisfactory into a source of benefit. He laments that a perfected scheme for a sanatorium (otherwise infectious disease hospital) was at the last moment upset by the perversity of certain landowners, but he has to report that a gentleman of large public spirit, Mr. W. Kitson, has come forward and relieved the sanitary authority from an awkward difficulty by presenting to them, for the use of the town, a plot of ground admirably adapted for the site of a "sanatorium." All honour to the generous giver! Mr. Karkeek is far from satisfied with the flushing arrangements of the sewers, but he is in good hopes to see this soon amended. The works necessary for the continuous supply of water to the town are advancing. The construction of new houses is carefully supervised, thanks to the cordial co-operation of the manor authorities with the sanitary authority. Systematic inspections are carried out with benefit; but alas! the death-rate was not so low as the medical officer of health says it should have been, and this, the loss of the sanatorium for the meantime, and the defective flushing sewers, have made Mr. Karkeek unhappy. But no doubt the increase of the death-rate, and, at any rate, the more noticeable deaths, are made a cause of converting evil into good. Six deaths were registered from typhoid fever; all occurred in houses in which the sickness was associated with sanitary defects. These deaths were made the occasion of inducing over two hundred householders to have their houses examined, with a view of making them fever proof, and of these houses one hundred and fifty had their sanitary appliances altered according to the most approved plans.

GRATUITOUS REVACCINATION OF CHILDREN.

At a recent meeting of the Chelsea Vestry Dr. Barclay, the medical officer of health, reported that the public vaccinator had revaccinated some youths under fifteen years of age, for which he was entitled to no remuneration. The present epidemic prevalence of small-pox in some parts of London renders it especially advisable that some provision should be made to secure the revaccination of all children between the ages of twelve and fifteen years who bear no vaccination marks, or whose marks are of such a character as afford evidence of imperfect vaccination and scant protection from small-pox. As the Local Government does not sanction any payment for revaccination of children under fifteen years of age, Dr. Barclay supported an application for the sanction of the Vestry to the payment for such cases performed by the public vaccinator during the next two months. The proposition was referred to the Sanitary Committee for report. The increasing number and proportion of fatal cases of small-pox occurring among children at these ages suggest the most urgent reasons for the adoption of Dr. Barclay's suggestion in Chelsea, and for similar action on the part of other metropolitan sanitary authorities. [Revaccination may be given at the public expense if the applicant has attained the age of fifteen years, or, if during any immediate danger of small-pox, the age of twelve years, and has not before been successfully vaccinated.]

CEMETERIES.

The Local Government Board have quickly followed up the publication of Dr. Franklin H. Parson's memorandum on the Sanitary Requirements of Cemeteries, with a series of model by-laws for the guidance of sanitary authorities who establish cemeteries under the Public Health (Interments) Act, 1879, in their management. The by-laws are only twelve in number, but appear to provide for the essential requisites, from a sanitary point of view, of the interment of bodies. A circular letter accompanying the by-laws points out that the power of making by-laws is only one of several means which the local authority may employ for the proper control of their cemetery.

A question of nuisance from certain "butterine" works came recently before the stipendiary magistrate at Birkenhead. "Tallow-melting" and "butterine" manufacture appeared to have been treated pretty much as equivalent terms in this case, a dash of "essence of putridity" (to use the words of one of the medical witnesses) being added to the customary stench of tallow-melting. A fine of £5 with 8*s.* costs was inflicted on the defendants.

The Chelsea Vestry have had under consideration the case of a woman going backwards and forwards from one part of the parish to another to visit her mother, reputed to be suffering from consumption, but who, it afterwards proved, was lying ill with small-pox. The Metropolitan Board of Works has been appealed to by the Vestry to assist in obtaining an amendment of the law to meet such a case, when opportunity occurs.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality is now considerably below its average for the season. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5690 births and 3267 deaths were registered last week. The births exceeded by 504, and the deaths by only 4, the average weekly numbers during 1880. The deaths showed a further decline of 80 from the recent weekly numbers; and the annual death-rate, which had been equal to 31·0, 28·0, and 22·9 per 1000 in the three preceding weeks, further fell to 22·4 last week. The lowest death-rates in the twenty towns last week were 17·5 in Newcastle-upon-Tyne, 18·0 in Birmingham, 18·7 in Bradford, and 18·7 in Portsmouth. The rates in the other towns ranged upwards to 25·8 in Leeds, 25·9 in Liverpool, 28·3 in Manchester, and 28·5 in Sunderland. During the past seven weeks of the current quarter the death-rate in the twenty towns averaged only 25·4 per 1000, against 27·2 and 28·1 in the corresponding periods of 1879 and 1880.

The deaths referred to the principal zymotic diseases in the twenty towns, which had steadily declined from 390 to 316 in the four preceding weeks, were 315 last week; these included 75 from whooping-cough, 68 from scarlet fever, 56 from small-pox, and 38 from fever, principally enteric. The annual death-rate from these seven principal zymotic diseases averaged only 2·2 per 1000 in the twenty towns, and ranged from 0·7 both in Plymouth and Wolverhampton, to 2·7 and 2·8 in Leeds and Liverpool. Scarlet fever showed the largest proportional fatality in Bristol, and whooping-cough in Leeds. Ten of the 14 deaths from diphtheria in the twenty towns occurred in London. The death-rate from fever (principally enteric) was highest in Sunderland, Liverpool, and Sheffield. Small-pox caused 56 more deaths in London and its suburban districts, one in Manchester, but not one in any of the eighteen other large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased in the sixteen preceding weeks from 77 to 683, further rose to 704 on Saturday last, a higher number than in any week since May, 1878. The number of new cases of small-pox admitted to these hospitals, which had been 234 and 176 in the two previous weeks, was 183 last week. The Highgate Small-pox Hospital contained 53 patients on Saturday last, against 30, 37, and 46 at the end of the three preceding weeks.

The deaths referred to diseases of the respiratory organs in London, which had been 702, 606, and 408 in the three previous weeks, further fell to 364 last week, and were no less than 135 below the corrected average number in the corresponding week of the last ten years; 211 were ascribed to bronchitis, and 94 to pneumonia. The annual death-rate from lung diseases (excluding phthisis) was equal to 5·1 per 1000 in London; the rate from the same diseases was equal to 10·0 in Liverpool.

In the twenty towns last week the causes of 87, or 2·7 per cent., of the deaths were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths did not exceed 1·1 per cent. in London, while it averaged 4·1 per cent. in the nineteen provincial towns. No uncertified deaths were registered last week in Newcastle-upon-Tyne, while their proportion was largest in Hull and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate averaged 23·9 per 1000 last week, against 34·7, 28·9, and 24·3 in the three preceding weeks; this rate was, however, 1·5 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 13·6 and 19·7 in Perth and Greenock, to 26·0 and 29·7 in Leith and Paisley. The deaths referred to the principal zymotic diseases in the eight towns, which had been 125, 94, and 89 in the three previous weeks, further declined to 87 last week, and were equal to an annual rate of 3·4 per 1000, which was 1·2 above the average rate from the same diseases in the twenty English towns. The zymotic death-rate in the eight Scotch towns ranged last week from 0·6 and 1·9 in Greenock and Perth, to 5·3 and 6·1 in Paisley and Leith. The fatal cases of scarlet fever in the eight towns showed a further decline last week to 13, of which 7 occurred in Edinburgh, 4 in Glasgow, and 2 in Leith. The 22 deaths from whooping-cough also showed a further decline from recent weekly numbers; they included 14 in Glasgow, 4 in Edinburgh, and 2 in Paisley. The 17 fatal cases of diphtheria, on the other hand, showed a further slight increase; 7 occurred in Glasgow, 3 in Edinburgh, 3 in Dundee, and 2 in Paisley. The deaths referred to "fever," which had been 10 and 8 in the two previous weeks, rose again to 10 last week, and included 5 in Glasgow and 2 in Edinburgh; the annual death-rate from fever in the eight towns averaged 0·40 per 1000 last week, against 0·26 in the twenty English towns. Four of the 6 deaths from measles and 11 of the 19 from diarrhœa were returned in Glasgow; the fatal cases of diarrhœa continue to show an excess for the season. The deaths referred to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy), in the eight Scotch towns, which had been 348, 261, and 200 in the three preceding weeks, further declined to 193 last week, and were equal to an annual rate of 7·6 per 1000; the death-rate from the same diseases in London did not exceed 4·4 per 1000. The largest excess in the fatality of lung diseases in the Scotch towns occurred last week in Glasgow, Aberdeen, and Paisley.

HEALTH OF DUBLIN.

The rate of mortality in Dublin showed a further decline last week, although it still shows a marked excess upon that prevailing in the large English and Scotch towns. The annual death-rate from all causes in the city, which had steadily declined from 47·4 to 41·8 in the three preceding weeks, further fell last week to 38·5. During the past seven weeks of the current quarter, however, the death-rate in the city has averaged no less than 41·0 per 1000, against 24·9 in London, and 23·2 in Edinburgh. The 246 deaths in Dublin last week included 31, or nearly 13 per cent., which were referred to the principal zymotic diseases, against 21 and 22 in the two previous weeks. These 31 zymotic deaths included 17 from fever (typhus, enteric or typhoid, and simple continued), 7 from whooping-cough, 3 from scarlet fever, 2 from diarrhœa, one each from measles and diphtheria, and not one from small-pox. The annual death-rate from these zymotic diseases was equal to 4·9 per 1000 in Dublin last week, while it did not exceed 2·5 in London, and 3·8 in Edinburgh. The deaths referred to fever, which had been 17 and 7 in the two previous weeks, rose again to 17 last week, and was equal to an annual death-rate from fever which was more than ten times as high as the average rate from the same cause last week in the twenty large English towns. The fatal cases of whooping-cough in Dublin last week exceeded the numbers in recent weeks, while those of measles and scarlet fever showed a decline. The deaths of infants and of elderly persons showed a considerable decline from recent weekly numbers.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

TOTTENHAM SANITARY ASSOCIATION.

Last week, with reference to a decision of the Local Board of Tottenham, that the annual report of their medical officer of health should be "amended and revised"—in other words, "cooked"—before being published, we asked what had become of this Association. We are glad to find from its report for 1880, which has just come to hand, that it exists, and is still pursuing its useful function of keeping the inhabitants of the place informed, independently of the sanitary authority, of the health condition and interests of the place. So long as this Association does the work it has set itself to do, we feel pretty sure that any attempts of the sanitary authority to escape from the performance of its proper duties will be frustrated. The report shows that the population of Tottenham is still very largely increasing, and that it now far exceeds the Registrar-General's estimate. According to the latter the death-rate of the district in 1880 was 19·12 per 1000; but according to the Association it did not exceed 16·55. Without losing sight of the influence exercised on infant mortality by improper feeding and ignorance in management, the Association is of opinion that in Tottenham unwholesome conditions arising out of defective sanitary arrangements play a prominent part in determining fatal infantile diarrhœa, and not without good cause they point to a marked reduction of the mortality in Tottenham of late years concurrently with great improvements effected in the ventilation of the sewers and the purity of the water-supply. Several interesting particulars are given indicative of a gradual deterioration of the water-supply of the district, a deterioration which, having regard to the previous history of the water-supply, should enlist the very serious attention of the sanitary authority.

SANITARY ECONOMICS.

What sort of men can those have been who formed the deputation despatched by the St. Pancras Vestry to the north on the recent "dusting and slopping" tour? They discovered that Manchester had adopted the questionable policy of competing with the ratepayers, by carrying on the trades of machinists, carpenters, builders, wheelwrights, tinmen, brushmakers, and others, in order to cheapen the cost of getting rid of objectionable refuse. The deputation deprecates competition with the ratepayers themselves by a local authority, "unless such competition is a necessary result of operations for the sake of public health." Applied to St. Pancras, the argument would be that the Vestry had no right to spend the rates in competition with, and injuriously to, that exceedingly praiseworthy body of men, the "dust contractors," even for the sake of public health. The deputation visited Manchester and inspected the works so perfunctorily that they did not even get an inkling of the great public-health experiment of which they form a part, and failed even to ascertain that there was more to learn from the mode of dealing with Manchester ash-tubs for London purposes than from the filthy, wet contents of middens in Leeds.

The Town Council of Aberdeen has the disposal of the following appointments: medical officer of the Council as local authority, police surgeon, medical attendant at the epidemic hospital, medical attendant at the gasworks, examiner of the quality of the gas, and inspector under the Dairies, Cowsheds, and Milkshops Order of July, 1879. The total sum paid by the Council for the performance of these duties by the various parties holding office amounts to £213 per annum. It is now the intention of the Council to combine these appointments, and to vest them in one and the same person. For this post they propose to obtain the services of a properly qualified medical practitioner, who shall receive a salary of £300, and a house rent-free at the epidemic hospital. He will be expected to devote his whole time and attention to the duties of the office.

Some time ago the Glasgow Local Authority issued certain regulations with reference to the manner in which dairies should be conducted. Amongst those was a rule that there should be no direct communication between the dairy proper and any apartments used as sleeping or living rooms. Sheriff Balfour, however, has now decided that in issuing this order the Local Authority overstepped the powers conferred on them by the Privy Council, and that the power to make such a regulation resides with the Council itself.

The Society of Arts will hold a third Congress on Domestic Economy in 1881. Seven bronze medals, also certificates of merit, are offered for competition to teachers of public elementary schools and training colleges. The subjects include clothing and washing; the warming, cleaning, and ventilation of the dwelling; the management of the sick-room and cottage; of income, expenditure, and savings; and food, its composition and nutritive value, its functions, and its preparation and culinary treatment.

A dairy-keeper has been fined £2 and 12*s*. 6*d*. costs at Aston, for obstructing a sanitary inspector whilst obtaining a sample of milk. The dairy-keeper (a woman), after having served the milk, and ascertained for what purpose it was going to be applied, seized the jug containing the sample from the inspector and threw the contents on the ground.

THE SERVICES.

RIFLE VOLUNTEERS.—5th Surrey Corps: Acting Surgeon George Farr White to be Surgeon. 2nd Derbyshire Corps: Alfred Chawner, gent., to be Acting Surgeon. 1st Roxburgh and Selkirk Corps: Acting Surgeon Alexander Dewar, M.D., to be Surgeon.

YEOMANRY CAVALRY. — Duke of Lancaster's Own: William Wingate Saul, Esq., M.D., to be Surgeon, vice J. D. Moore, deceased.

ADMIRALTY.—Mr. Henry S. Halahan has been appointed Surgeon and Agent at Telin and Malinore.

INSTRUCTIONS FOR VACCINE INOCULATION BY EDWARD JENNER.

Read before the Epidemiological Society, Feb. 2nd, 1881, from an unpublished manuscript in the possession of FREDERICK SYMONDS, Esq., *of Oxford.*

BY DR. SQUIRE.

THE valuable autographs of Dr. Edward Jenner were submitted to the inspection of the members present.

One point of great interest and value in the early part of these "Instructions" is Jenner's description of the course of vaccinia at this early period of its human history. This should be compared with Dr. Gregory's description of inoculated small-pox, with which it closely agrees, to show the natural affinities of the two; it affords also an important standard of comparison with vaccinia as now produced, by which we may take care that the true type is perfectly maintained.

Instructions
FOR
VACCINE INOCULATION.

Let the vaccine fluid be taken, for the purpose of inoculation, from a pustule that is making its progress regularly, and which possesses the true vaccine character, on any day from the fifth to the eighth, or even a day or two later, provided the efflorescence be not then formed around it. When the efflorescence is formed, it is always most prudent to desist from taking any more of the virus from that pustule.

To obtain the virus, let the edges of the pustule be gently punctured with a lancet in several points. It will gradually ooze out, and should be inserted upon the arm about midway between the shoulder and elbow, either by means of a very slight scratch, not exceeding the eighth part of an inch, or a very small oblique puncture.

A little red spot will appear on the punctured part on the third day, if the operation succeed, which on the fourth or fifth becomes perceptibly vesicated. It goes on increasing till the tenth day, when it is generally surrounded by a rose-coloured efflorescence, which remains nearly stationary for a day or two. The efflorescence then fades away, and the pustule is gradually converted into a hard, glossy scab, of a dark mahogany colour. These progressive stages of the pustule are commonly completed in sixteen or seventeen days.

A single pustule is sufficient to secure the constitution from the small-pox; but as we are not always certain the puncture may take effect, it will be prudent to inoculate in both arms, or to make two punctures in the same arm, about an inch and a half asunder, except in very early infancy, when there is a great susceptibility of local irritation.

If the efflorescence surrounding the pustule should be extensive, and occasion much local heat upon the arm, it may be cooled by the repeated application of pieces of folded linen dipped in cold water, or still more expeditiously by a strong solution of the aqua lythargyri acetati in water; an ounce, for example, of the former in five or six of the latter.

If the scab should at any time be prematurely rubbed off, the part may be occasionally touched with the undiluted aqua lythargyri acetati.

Vaccine virus, taken from a pustule, and inserted immediately in its fluid state, is preferable to that which has been previously dried; but as it is not always practicable to obtain it in this state, we are compelled to seek for some mode of preserving it. Various means have been suggested, but from the test of long experience it may be asserted, that preserving it between two plates of glass is the most eligible. Let a piece of common window-glass be cut into squares of about an inch each, so that they shall lie smooth when placed upon each other. Let the collected vaccine fluid be confined to a small spot (about the size of a split pea) upon the centre of one of these glasses, which should be suffered to dry in the common heat of the atmosphere without exposure to the heat of fire or the sun. When dry, it should be immediately secured by placing over it the other piece of glass. Nothing more is necessary for its preservation than wrapping it in clean writing paper.

The virus, thus preserved, when wanted for the purpose of inoculation, may easily be restored to its fluid state by dissolving it in a small portion of cold water, taken up on the point of a lancet. It may then be used in the same manner as when just taken from a pustule.

The vaccine fluid is liable, from causes apparently trifling, to undergo a decomposition. In this state it sometimes produces what has been denominated the spurious pustule—that is, a pustule or an appearance on the arm not possessing the characteristic marks of the genuine pustule. Anomalies, assuming different forms, may be excited, according to the quantities of the virus applied, or the state of the person inoculated; but by far the most frequent variety, or deviation from the perfect pustule, is that which arrives at maturity, and finishes its progress much within the time limited by the true. Its commencement is marked by a troublesome itching, and it throws out a premature efflorescence, sometimes extensive, but seldom circumscribed, or of so vivid a tint as that which surrounds the pustule completely organised, and (which is more characteristic of its degeneracy than the other symptoms) it appears more like a common festering produced by a thorn, or any other small extraneous body sticking in the skin, than a pustule excited by the vaccine virus. It is generally of a straw colour; and when punctured, instead of that colourless, transparent fluid of the perfect pustule, its contents are found to be opaque. That deviation from the common character of the pustule, arising from vaccine virus which has been previously exposed to a degree of heat capable of decomposing it, is very different. In this instance it begins with a creeping scab of a pale brown or amber colour; making a long and slow progress, and sometimes going through its course without any perceptible efflorescence. Its edges are commonly elevated, and afford, on being punctured, a limpid fluid.

A little practice in vaccine inoculation, attentively conducted, impresses on the mind the perfect character of the vaccine pustule; therefore, when a deviation arises, of whatever kind it may be, common prudence points out the necessity of re-inoculation, first with vaccine virus of the most active kind; and secondly, should this be ineffectual, with variolous virus. But if the constitution shows an insusceptibility of one, it commonly does of the other.

When any constitutional symptoms occur in inoculated cow-pox they are commonly first perceptible (especially in children) on the fourth or fifth day. They appear again, and sometimes in adults, not unlike a mild attack from inoculated small-pox, on the eighth, ninth, or tenth day; the former arise from the general effects of the virus on the habit, the latter from the irritation of the pustule.

If the effluvia of the small-pox have been received into the habit previously to the inoculation of the vaccine virus, the vaccine inoculation will not always be found to stop its progress, although the pustule may make its advances without interruption.

The lancet used for inoculation should always be perfectly clean. After each puncture it is proper to dip it into water, and wipe it dry.

The preservation of vaccine virus upon a lancet beyond the period of a few days should never be attempted, as it is so apt to produce rust, which will decompose it.

EDWARD JENNER.

THE NEW WING AT UNIVERSITY COLLEGE.

PRESS of matter prevented us from noticing last week the banquet which was given on the 16th inst. at University College to inaugurate the new north wing which has recently been completed. The company was an unusually brilliant assemblage of many of the most cultivated minds in the country. It is seldom that one can see assembled round the same table the Presidents of the Royal Society, the Royal Academy, the College of Physicians, the College of Surgeons, the Institute of British Architects, the General Medical Council, and the Institute of Civil Engineers, together with such well-known men as Huxley, Tyndall, Lister, John Marshall, Burdon-Sanderson, Michael Foster, Williamson, and Roscoe; Browning, Max Müller, Henry Morley; the Master of the Rolls, Mr. Justice Grove, Mr. Justice Fry, and the Solicitor-General; Mr. Poynter, Mr. Alma Tadema, Mr. Legros, Mr. Boehm, Mr. Alfred Waterhouse, and nearly a hundred others, all, more or less, eminent in science, art, law, or literature. Those who remember the ridicule which was cast upon the "university we've got in town," when it was established in 1828, must now recognise that the highest aspirations of its founders have been fulfilled, and one fact mentioned at the dinner by the Master of the Rolls—that besides himself three other judges on the bench (Justices Fry, Lindley, and Watkin Williams), as well as the Solicitor-General, were pupils of the College—is a sufficient evidence that the education given by the College to its alumni has enabled them to compete successfully with those who have been educated on the banks of the Isis or the Cam. The new wing, erected at a cost of £35,000 (of which £14,000 remains unpaid), has enabled the College to very greatly increase its resources for the teaching of fine arts, zoology and comparative anatomy, physiology, and chemistry. One side of the wing looks to the north, and on this side as much glass has been used in the construction as is permitted by the Building Act. This splendid range of north lights has been utilised for the microscopic and artistic purposes for which a north light is absolutely indispensable.

Of the additions to the Slade School of Fine Arts we need say nothing, excepting that, in the words of Sir Frederick Leighton, "no such machinery for teaching fine arts is to be found elsewhere in England outside the walls of the Royal Academy." The department of Zoology and Comparative Anatomy, under the control of Professor Lankester, has had added to it—1. A large museum (49 ft. by 41 ft.), well stocked with zoological specimens. 2. A south museum (43 ft. by 44 ft.), which is notable for containing a fresh-water and a salt-water aquarium. "The marine aquarium consists of an upper and a lower tank, half the water being daily raised from the lower to the upper tank by means of a vulcanite pump, whence it is allowed to flow back again into the lower tank, so as to ensure its oxygenation. The fresh-water aquarium is provided with a constant stream, and is specially intended for the hatching of fish and the study of the diseases of our river fishes." 3. A large practical class-room, provided with microscopes, lamps, water-supply sinks, &c., in which fifty students can dissect at once. 4. A professor's laboratory. 5. An attendant's gallery, for containing various necessaries for the course of instruction, as well as a large tank on the roof for storing fresh-water mussels, crayfish, frogs, &c. 6. Two large laboratories especially arranged for original research, as well as an assistant's laboratory.

The whole of the upper floor of the new wing is occupied by the department of Physiology. This consists (1) of a lecture theatre, capable of seating 170 students, and which can be darkened at will, when necessary, for the performing of experiments; (2) a large student's working-room, capable of accommodating 100 students. Each worker is supplied with gas and water, and a locker for keeping microscopes and other necessaries. This room is lighted by a large window looking north.

Six other rooms, called the Jodrell rooms, in memory of Mr. Jodrell, who endowed the Professorships of Physiology and Zoology, are intended for advanced students and for the purposes of original research. One room is especially fitted for chemical research, a second for the analysis of gases, a third for experiments on muscle and nerve, and a fourth for investigations relating to respiration, circulation, and animal heat.

The Chemical Department, in addition to a theatre capable of accommodating 400 students, and the Birkbeck Laboratory (now devoted to the department of applied science and technology), comprises a new laboratory of noble dimensions with a lofty open roof, affording room for fifty students. Here is an ingenious apparatus for passing sulphuretted hydrogen through solutions without allowing the escape of gas into the room, as well as a range of water baths heated by steam. There is also a water air-pump and a Sprengel pump, and a reservoir of distilled water.

There is a furnace room also, and arrangements for evaporating without fouling the air. There are nine other rooms devoted to the teaching of chemistry—viz., a professor's research laboratory, room for gas analysis, balance room, assay room, spectroscope room, &c. &c. The Department of Chemical Technology, by the increased space now allotted for pure chemistry, has been much enlarged, and the courses of study specially designed for metallurgists, alkali manufacturers, &c., glass manufacturers, bleachers, brewers, agriculturists, &c., will henceforth be carried out with increased effectiveness by Professor Graham.

INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.

THE detailed prospectus of this Exhibition, together with the regulations for exhibitors, has now been published, and the prospectus printed in the three official languages of the Congress is being issued by the secretaries of sections to British and foreign medical practitioners. The Exhibition Committee, which is now completed, consists of Mr. Erichsen (chairman), Mr. Berkeley Hill (treasurer), the President of the Pharmaceutical Society (Mr. Greenish), Mr. Cantlie, F.R.C.S., Professor Corfield, Mr. Eassie, C.E., Mr. Rogers Field, M.I.C.E., Mr. George Godwin, F.R.S., Mr. Meredith, M.B., Mr. Edmund Owen, F.R.C.S., Dr. Poore, Mr. E. C. Robins, F.S.A., Mr. Roger Smith, F.R.I.B.A., Dr. Steele and Mr. Judge (secretary). The Exhibition, which is to be held in the Exhibition Building at Kensington-gore, will comprise everything that is of service for the prevention, detection, cure, and alleviation of disease, and will be divided into three sections.

A. MEDICAL SECTION.—1. Surgical instruments and apparatus. 2. Appliances of the ward and sick-room. 3. Drugs, disinfectants, medical dietetic articles, and mineral waters. 4. Electrical instruments and appliances. 5. Microscopes and optical apparatus. 6. Apparatus of other kinds used in the investigation of disease. 7. Appliances used for the treatment of sick and wounded during war; street ambulances, &c. 8. Appliances used in teaching medicine. 9. Books, diagrams, models, &c.

B. SANITARY SECTION.—1. Domestic and hospital architecture. 2. Planning, construction, and decorative materials.

3. Ventilation, lighting, and warming. 4. Waterclosets, sinks, baths, &c. 5. Sewerage and drainage. 6. Water supply and filtration. 7. Health resorts and sanitaria. 8. Books, diagrams, models, &c.

C. MISCELLANEOUS SECTION.—Applications of hygienic principles to food and dietaries, clothing, &c.; school furniture and other articles more or less connected with the general purpose of the Exhibition.

Intending exhibitors will have the opportunity of taking either floor-space or wall-space, according to their requirements, and arrangements will be made for portfolios (containing architectural plans of hospitals, sanitaria and domestic houses, &c.) to be hung against the wall. The Committee also express their readiness to take charge of single articles sent by one exhibitor, so that inventors of new instruments, &c., will have an opportunity of displaying their work. The Committee are endeavouring to secure a large number of exhibitors, and a limit has been placed upon the amount of space which any one exhibitor may occupy. Arrangements will also be made (should it be found necessary) for the exhibition of machinery in motion, and it is possible that the medical public may have an opportunity of seeing some of the processes employed by opticians, surgical cutlers, and wholesale pharmacists. No secret preparations will under any circumstances be exhibited. Articles for exhibition will be received from July 1st to July 9th, so that an entire week will be devoted to the final arrangement of the exhibits before the opening day. Exhibitors are to have the privilege of selling articles to visitors during the last week of the Exhibition, and many visitors to the Congress will, doubtless, appreciate the opportunity thus afforded them of taking away with them any articles which they may fancy. Certificates of merit will be awarded, and the appointment of the judges for this purpose will be proceeded with forthwith. Applications for space must be made on the official form and be addressed to the Secretary of the Exhibition Committee, Parkes Museum of Hygiene, University College, London, W.C. Applications from Great Britain and Ireland and the continent of Europe must be made not later than March 31st, 1881. Applications from India, the Colonies, and America will be received up to Saturday, April 16th, 1881. Directly the space has been allotted the compilation of the catalogue will be preceded with, and the Committee hope that by getting the catalogue in hand at an early date to be able to make it a really serviceable handbook to the Exhibition.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Thursday, the 17th inst., Mr. A. O'Connor gave notice that he would move for the following returns:—Army (Medical Service)—Address for returns of the number of examinations held in London since 1870, inclusive, for appointments in the Army Medical Service. Of the number of vacancies to be filled at the date of each examination. Of the number of candidates who presented themselves at each examination. Of the number of unsuccessful candidates at each examination. And, of the nature and dates of the registered medical qualifications of each candidate at each examination (the candidates to be designated not by their names, but by numbers or letters. Navy (Medical Service)—Returns of the number of examinations held in London since 1870, inclusive, for appointments in the Navy Medical Service. Of the number of vacancies to be filled at the date of each examination. Of the number of candidates who presented themselves at each examination. Of the number of unsuccessful candidates at each examination. And, of the nature and dates of the registered medical qualifications of each candidate at each examination (the candidates to be designated not by their names, but by numbers or letters).

On Monday returns relating to examinations for the Army and Navy Medical Services were ordered, on the motion of Mr. Arthur O'Connor.

On Tuesday the order for the second reading of the Medical Appointments Qualifications Bill was further deferred for a week. Mr. Loder has given notice that he will move the rejection of the Bill.

Trichinosis.

Admiral Sir John Hay asked the Secretary to the Admiralty if the Admiralty are taking precautions in regard to the ration of pork for the Navy in consequence of the serious outbreak of trichinosis in America, which has caused the French Government, as reported, to forbid the importation of American pork. Mr. Trevelyan explained that about a third of the pork supplied to the Navy was Irish, and two-thirds were Danish. To substitute American pork would be a distinct breach of contract, which it would be comparatively easy to detect. The Admiralty exercised great care in dealing only with reputable and responsible firms. Mr. Dixon-Hartland asked the Vice-President of the Council if he had seen that the importation of pork from the United States has been prohibited in France, Russia, Italy, Austria, Spain, Portugal, and Greece, in consequence of the prevalence of trichinosis and the hopelessness of inducing the poorer classes to disinfect the pork and so prevent disease, and whether he was prepared to forbid its introduction into Great Britain and Ireland. Mr. Mundella had no official information that the foreign Governments named had prohibited the importation of pork from the United States, but was making inquiries. The annual importation of bacon, pork, and hams into this country exceeded five millions and a quarter cwt., or more than 20 lb. per head for the whole population, and the estimated value exceeded nine millions and a half sterling. It nearly all came from the United States, Canada, Germany, and Belgium, and the figures he had given were exclusive of live swine. Obviously, to cut off such an enormous supply of animal food would inflict great hardship upon the poorer classes, and could not be done except under the most urgent necessity, and after the gravest consideration. They could not cut off the American supply without cutting off that from other countries, where trichinosis also existed, and if the American supply were cut off here, and admitted elsewhere, we should get it secondhand. Having made inquiries through the Local Government Board, he found no report of any outbreak of trichinosis in the country. Two years ago there was a report of such an outbreak on board a training-ship, but upon investigation the medical authorities were satisfied that it was not trichinosis. In 1879 the Duke of Richmond, in reply to a question, called attention to the fact that safety was only to be found in thoroughly cooking the pork. It was only reasonable to suppose that the practice of using smoked sausages and ham, and half-cooked food, contributed very largely to the dissemination of the disease on the Continent, but that was not the practice in this country, where the risk of affection was effectually disposed of by efficient cooking at a high temperature.

On Wednesday Sir Eardley Wilmot brought in his Bill for the total abolition of vivisection, and put it down for second reading on Wednesday, 23rd March. The names on the back of the Bill are those of Sir Eardley Wilmot, Mr. Samuel Morley, and Mr. Firth. The Select Committee of the House of Commons appointed to consider the operation of the Contagious Diseases Act met in room 12, and the Hon. W. N. Massey was reappointed chairman. The committee will meet on Wednesday next to take evidence.

On Thursday, in reply to Lord Rendlesham, Mr. Dodson stated that as at present advised, he believed attendants at lunatic asylums did not come under the regulations of the "Employers' Liability Act;" but the question was one of legal construction, which might have to be officially decided hereafter.

Mortality of Ashton-under-Lyne.

In answer to Mr. Hugh Mason, Mr. Hibbert said the attention of the Local Government Board had been drawn to the statement in the Registrar-General's quarterly return respecting the very high mortality recently at Ashton-under-Lyne. In November last the Board wrote to the Town Council, referring to the fatal prevalence of diarrhœa, and asking what the medical officers of health had been able to discover about the cause of it; but no reply had yet been received to that letter. The Local Government Board propose to direct an inquiry by one of their medical inspectors into the cause of the high death-rate of the borough.

HUNTINGDON COUNTY HOSPITAL.—According to the report of the Board of Management of this hospital, read at the annual meeting of the governors last week, the gross receipts of the institution during the year were £1588 19*s.* 4*d.*, while the expenditure amounted to £1506 12*s.* 4*d.* In-patients to the number of 213, and 714 out-patients, received the benefits of the charity during the same period, in addition to 201 casualties.

PARIS.

(*From our own Correspondent.*)

FROM what has recently been written in the lay press, it would appear that a large proportion of American pork contains trichinæ, and as forty million barrels of this meat are said to be imported annually from America, it has become necessary to take steps to protect the public from the danger which menaces them. An official instruction was circulated a few weeks since calling the attention of food inspectors to the question, and a large quantity of meat was in consequence seized, and found to be diseased. At the Academy of Medicine a sitting was also devoted to the subject, and various schemes for protecting the public were proposed by different speakers. The matter has now, however, been settled by a decision, made by the Minister of Commerce, on the recommendation of the Council of Hygiene, which forbids any further introduction of American salt pork into the country.

Another decree, emanating from the same source, concerns the use of salicylic acid in the preservation of food. Manufacturers of tinned provisions, brewers, and winemakers have for some time employed salicylic acid and the salicylates for this purpose. It has been found especially useful for keeping beer, and competent judges have thought that there was no objection to the use of such small quantities as are necessary for this purpose. But the Council of Hygiene has deliberated, and on the strength of its wisdom a ministerial *fiat* renders the use of salicylates a punishable offence.

The *France Médicale* publishes the account of a case of chronic bronchitis, which was cured by a treatment not often used in England. The paper is too long to transcribe here *in extenso*, but the main points are worthy of notice. The patient, a young woman aged twenty, had suffered from chronic bronchitis for three years, when she became an inmate of the Hôpital de la Pitié. On Oct. 6th, 1880, her condition was as follows :—The face was red and puffy ; general condition good ; no œdema of the legs. There was great dyspnœa, which rendered any active occupation impossible ; the cough was constant and paroxysmal, and there were suffocative attacks at night ; abundant mucous and mucopurulent expectoration ; increase of thoracic resonance, which was almost tympanitic at the bases ; vesicular murmur weakened ; sibilant and snoring râles, with moist rhonchus all over both chests ; heart-sounds normal ; no increase of temperature at night ; pulse regular, strong, and of moderate tension. No albuminuria. Tongue clean ; appetite good ; digestion normal. Frequent and profuse perspiration, especially after the attacks of suffocation. Until November 27th everything which had been administered had failed to relieve, the condition of the patient remaining much the same. It was then decided to try the effect of counter-irritation by ignipuncture. A first application was made at once with a thermo-cautery, a large number of very superficial punctiform cauterisations being disseminated over the dorsal region. The following day there was a marked improvement in every respect ; the patient had slept better, cough and dyspnœa were less, and there was not so much moist râles. On the 30th of November and on the 3rd of December the application was renewed, the cough then ceasing entirely, and the dyspnœa being so slight that the patient was able to walk up and down stairs without fatigue. On auscultation no râle of any kind ; and whilst the vesicular murmur was to be heard well all over the lungs the emphysematous resonance had much diminished. On the 7th, 15th, and 21st of December further cauterisations were made, to ensure a thorough cure. On the 29th the patient took her discharge in perfect health, physical examination showing nothing beyond a slight want of elasticity over the right apex and a slight roughness of breathing in the corresponding supra-spinous fossa. The result obtained in the preceding case by the use of the actual cautery was, no doubt, unusually complete, but the method of treatment is constantly employed with success in Paris, being perhaps somewhat neglected at the present day in England. Besides chronic bronchitis, other affections of the lungs may be benefited by ignipuncture, incipient consolidation, and unabsorbed pleuritic effusion being worthy of a special mention. The thermo-cautery also plays a prominent part in the French treatment of many spinal complaints; it is the sedative *par excellence* in locomotor ataxia, and to a lesser extent in both varieties of trembling paralysis (paralysis agitans—*sclérose en plaques*).

The *Progrès Médical* records another case of nerve-stretching, this time for congenital epilepsy. The patient, who is under the care of M. Voisin, has been improved. Professor Ball has also performed the operation for painful hemiplegia. The result has been entirely negative.

Obituary.

WM. RUTHERFORD SANDERS, M.D. EDIN.

THE death of Professor Sanders, by apoplexy, at his residence in Charlotte-square, on the 18th inst., will be regarded by all who know the medical circumstances of Edinburgh and the University as one of the most serious events which has happened since the death of the younger Dr. Begbie. The death of Dr. Andrew Wood was more startling and unexpected, but that was at threescore years and ten. This is at the comparatively early age of fifty-seven. He was just beginning to realise the most splendid career of success which is open to an Edinburgh consulting physician, after a long and slow period of waiting and training. Before studying medicine in Edinburgh Dr. Sanders studied in Montpelier, where he took the degree of Bachelor of Letters. Dr. Sanders graduated in medicine in the Edinburgh University in the year 1849, taking for the subject of his thesis "The Anatomy of the Spleen." This thesis was a work of such merit as to gain one of the gold medals of the year. His principal published works were his thesis, which appeared in Goodsir's Annals of Anatomy and Physiology, 1859; the article on Paralysis in Reynolds's "System of Medicine;" contributions on Waxy Degeneration in the "Edinburgh Medical Journal," 1853 and 1854; an admirable paper on "The Seat of Lesion in Facial Paralysis," in THE LANCET of 1865, &c. &c. His writings show a deep acquaintance with the best physiological and pathological works of the time, an anticipation of the drift of such work, and an acquaintance with modern languages which enabled him to go to original sources. For many years before his election to the chair of pathology in the University he was one of the physicians of the Royal Infirmary of Edinburgh, and an extra-mural Lecturer on Physiology and Clinical Medicine. In the year 1869 he was elected, the third professor, to the chair of General Pathology, created in 1831, and filled, in succession, previously to Dr. Sanders's appointment, by Dr. John Thomson and Dr. William Henderson.

We have been favoured with a notice of Professor Sanders from one who, by intimate sympathy and long friendship and co-operation, was well able to estimate his character and worth, and we cannot do better than append it in full, only further premising that Dr. Sanders was related by marriage to Professor T. Gairdner, and that he leaves a widow and several children to feel his loss.

"Those who knew the hard preparatory work Dr. Sanders went through, as well as the character of his mind, can best understand the loss which his death occasions. Those who were associated with him when he filled the post of lecturer on physiology know how faithfully he discharged the duties of that arduous and, in the extra-mural school, not very encouraging position. The familiarity which he had with the use of the microscope, at a period when such familiarity was not common, he had acquired under the distinguished Henle, then in the Heidelberg school, and that early made him an authority in physiological and pathological histology. This physiological work, preceding his work at the hospital as a clinical teacher, helped largely to give him that power of seeing through the mists of a case which characterised him ; for his tendency, instead of magnifying the case and himself, was rather to beat down the mystery, as if saying, after a searching diagnosis, 'That is it, and that is all ; or, at least, all that can be said about it.'

"While this genuineness as a physician was due partly to the thoroughness of his physiological and pathological attainments, it was due no less to the straightforwardness of his character, which led him to despise those arts which are, perhaps, too often employed to impress patients and the public. He was known among us as an unassuming, genuine man, on whom we could rely for a sound diagnosis and candid opinion, and, even before he rose into prominence with the public as a consultant, he was one to whom his professional brethren, when suspecting that all was not right with themselves, would prefer to go for an opinion.

"As a teacher Dr. Sanders was conscientious and thorough, despising the quackeries of the lecture-room no less than of the sick-room, and besides being clear, had a warm earnest manner, the true eloquence of the medical lecture-room, all contributing to render him one of the most successful of teachers. As clinical teacher he took a great deal of trouble at the bedside, spending, we believe, even to the last, a couple of hours daily at the infirmary when he might have been making money elsewhere. His was the usual history of the deserving consulting physician: early resolve to rise by living laborious days, long years of hard work in comparative obscurity, followed by success, which, once begun, came on rapidly. He had for some time, to the satisfaction of all his friends (and it has been said he had no enemies), attained the foremost rank as consulting physician in Edinburgh, we may say in Scotland, second only to that of his attached friend and former colleague in the Edinburgh School, Dr. Gairdner, of Glasgow, with whom he maintained intimate relations.

"The death of Dr. Sanders will be felt as a severe loss. By the University as that not merely of one of its ablest teachers, but as an influence and an example in all right directions. Edinburgh and the profession in and around Edinburgh will miss him greatly as a consultant, whose place, as a whole, it will not be easy to fill. One of the sayings of Mr. Syme, in our student days, was that a man may be known by how he stands with his professional brethren; and, tried by that test, Dr. Sanders stood very high, for he enjoyed the entire confidence of his brethren, and, more than that, their personal esteem. His many former pupils now scattered over the world, will feel his death as to them a light gone out, and the inner circle of his friends, who have been his fellow-workers, are left to feel acutely the early fall of a comrade who had a deep hold on their affection as well as on their respect."

THOMAS WEMYSS BOGG, M.B. LOND., M.R.C.P.

OUR obituary column contains the name of Thomas Wemyss Bogg, M.B., who died on February 13th, at the early age of forty-four, at Altrincham, whither he had removed from St. Leonards-on-Sea in consequence of failing health.

Dr. Bogg was educated for the medical profession by his father, the late John Bogg Esq., surgeon, Louth, and having, after some years of diligent and careful study, matriculated at London University, he proceeded to University College, where his intelligence and assiduity speedily attracted the attention of the medical staff. In the class examinations he obtained the gold medal in botany, silver medals in senior anatomy, chemistry, and medicine, the prize in descriptive botany, and certificates of honour in practical chemistry, materia medica, junior anatomy, physiology, and surgery. At the First M.B. Examination he obtained honours in anatomy, botany, and chemistry, and gained the gold medal for botany at the Apothecaries' Hall. Having passed the College of Surgeons and the Hall, Dr. Bogg commenced the practice of his profession as assistant to his father in his native town. Dr. Bogg naturally stood very high in the estimation of the Professors at University College. On the occasion of his competing for a public appointment, Sir Wm. Jenner and Professors Ellis, Erichsen, Harley, Lindley, Quain, Sharpey, Walshe, and others bore concurrent testimony to Dr. Bogg's diligence and punctuality, professional knowledge, practical ability and excellence of general character as a student, qualities which future years of usefulness in his profession and blameless life confirmed.

Shortly after having graduated at London University as M.B., Dr. Bogg's health, which had for years been a cause of anxiety, led him to relinquish general practice and leave Louth. He did not leave Louth without many important expressions of respect from public authorities, showing that the same qualities which had stood him in such good stead at University College served him well in the graver stages of his life. After an interval of a year and a half spent in study, and in attendance at the Manchester Royal Infirmary and the Children's Hospital, Brompton, Dr. Bogg was admitted a member of the Royal College of Physicians, London. In May, 1878, he commenced practice as a physician at St. Leonards-on-Sea. Only four months later symptoms of diabetes appeared, and to this disease he finally succumbed on the 13th inst.

Dr. Bogg was a man of varied attainments, possessing high poetical talent. He loved his profession for its use to others, and found in it scope not only for the admirable practical skill which he had acquired, but also for that gentleness of spirit and sympathy which endeared him alike to those under his care, and to a very wide circle of friends. Like his friend, the late Mr. Henry Bateman, Dr. Bogg was a member of the New Church.

Various contributions to the pages of THE LANCET from the pen of Dr. Bogg have appeared, notably one on the important subject of "Disease and Prison Diet," in 1879. Dr. Bogg's interest in this subject probably originated in his experience as surgeon to the Louth gaol. In his letter to us he made some forcible remarks on the possible connexion between the reduction in diet of prisoners and the frequency of pneumonia. He made the important suggestion that a return of the infirmary cases of acute disease occurring in prisoners on low diet during any given year should be asked for by a member of Parliament. Dr. Bogg was, we believe, unmarried, and leaves a widowed and esteemed mother to feel the loss of rare filial services. He was brother of the late Dr. E. Beverley Bogg.

ROBERT CRYAN, F.K.Q.C.P., M.R.I.A.

THE death of this physician took place last week at his residence, Rutland-square, Dublin, after two days' illness, from pneumonia. He was connected with the Catholic University Medical School as lecturer on anatomy and physiology, and his illness was so sudden that early in the week he died he addressed his class in the lecture theatre, apparently in his ordinary health. He was Visiting Physician to St. Vincent's Hospital, and obtained the Fellowship of the King and Queen's College of Physicians in Ireland in 1873. Deceased was a kind and amiable gentleman, and was much esteemed and respected by a large circle of friends. The funeral took place last Saturday, the 19th inst., and was largely attended. A procession of students belonging to the medical school and hospital to which Dr. Cryan belonged, numbering over 100, followed the hearse, and on arriving at Glasnevin carried the coffin from the mortuary chapel to the place of interment.

At a meeting of the Faculty of Medicine, Catholic University Medical School, Dublin, held last week, the following resolution was unanimously adopted:—"That this Faculty deeply deplores the sad and untimely demise of their loved and respected colleague, Professor Cryan, F.K.Q.C.P., M.R.I.A., and that the Dean be instructed to convey this expression of their profound regret to the family of their late colleague." On the same day the students of St. Vincent's Hospital, to which the deceased was physician, passed a resolution deploring the loss of a gifted, painstaking, and learned instructor, and offering their heartfelt sympathy to his family in their sad bereavement.

Medical News.

APOTHECARIES' HALL.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise, on Feb. 17th:—

Dobrashian, Gabriel Sukias, Constantinople.

COLLEGE OF PHYSICIANS IN IRELAND.—During the February examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—James Stewart Brooke, James Joseph Davis, Edalji Dorabji Patel, Edmund Joseph Thunder.

MIDWIFERY.—James John Riordan, Edmund Joseph Thunder.

The undermentioned Licentiates have been duly admitted Members:—

William Berkeley Drew, Surg. R.N.; William Robert Kerans, Surg.-Maj. A.M.D.; Charles H. Leet; Geo. Alexander Moorhead; Joseph Michael Redmond.

THE new University College at Nottingham is approaching completion, and will be opened by Prince Leopold in June or July.

ST. MARK'S OPHTHALMIC HOSPITAL, DUBLIN.—A bazaar will be held at the end of this month to obtain funds to pay off the debt incurred by the late building and alterations.

The following gentlemen have received Government grants for successful vaccination in their respective districts: Mr. T. Torkington Blease of Altrincham, fourth time; Mr. Alfred Matcham, St. George's, Southwark, third time.

St. Luke's Hospital for Lunatics.—The annual meeting of the governors was held on Feb. 16th in the Board-room of this hospital in Old-street, under the presidency of General Sir Henry Percival de Bathe. The report for the year stated that the hospital continued in a prosperous state. During the year seventy-one patients were admitted, fifty-four were discharged, and nine died. The total number of patients admitted since the opening of the hospital on the 30th of July, 1751, was 22,968.

Trichinosis.—Mr. J. M. Redmond, L.K.Q.C.P.I., &c., writes to *The Times* from 126, Sandford-road, Dublin, under date 22nd of February:—"As I see from Mr. Chamberlain's answer that the Board of Trade are unable to afford any protection to the public in this matter, I think it my duty to state that two subjects came under my notice in the dissecting-room of the School of Medicine, Cecilia-street, Dublin, during the last fortnight, which on microscopical examination proved to be infested with trichinæ."

Presentations.—On the occasion of Dr. Banning leaving Gateshead, where he had been in practice for some years, for Dunblane, his professional brethren presented him with a handsome silver salver bearing the following inscription: "Presented to Robert J. Banning, M.D., by the members of the Gateshead Medical Society, as a token of their appreciation of his services as honorary secretary for fourteen years." The following resolution was also unanimously passed by the Gateshead School Board: "That this Board sincerely regrets to receive Dr. Banning's resignation, and acknowledges the assiduity, ability, and invariable courtesy which distinguished his work on the Board.——On the 5th inst., the oldest of the subordinate officers of the infirmary, St. George's-in-the-East, presented Dr. Belcher with a handsome silver inkstand, on his resignation of the post of superintendent of the institution, and in token of their esteem and appreciation of his kindness and worth. ——Dr. B. J. Massiah has been presented with a handsome timepiece by the officials and patients of the Barnes Convalescent Hospital, Cheadle, near Manchester, on the occasion of his resigning the position of Resident Medical Officer in that institution to become Visiting Physician to the Sick Children's Hospital, Pendlebury.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* The Lancet *before 9 o'clock on Thursday Morning, at the latest*

Bartlett, C. R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Morchard Bishop District of the Crediton Union.

Cohen, A., B.A., M.B., B.Ch., has been appointed Senior House-Surgeon to the Metropolitan Free Hospital, vice W. S. Byrne, resigned.

Cossham, W. R., M.D., C.M., M.R.C.S.E., has been appointed a Consulting Surgeon to the Cirencester Cottage Hospital.

Edmunds, R., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer to the Workhouse and the Panteague District of the Pontypool Union, vice Cousins, deceased.

Hall, C. S., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Carlisle Rural Sanitary District.

Hepburn, W. A., L.F.P.S.G. & L.S.A.L., has been appointed Medical Officer and Public Vaccinator for No. 2 District of the Durham Union, vice J. W. Blandford, M.R.C.S.E., resigned.

Hicks, E. B., L.R.C.P.L., M.R.C.S.E., has been reappointed Medical Officer of Health to the Easingwold Rural Sanitary Authority.

Hoskins, W., M.B., C.M., has been appointed Medical Officer for the Second District of the Poole Union.

James, C. E., M.B., L.R.C.S.I., has been appointed Second Surgeon to the Kilkenny County Infirmary.

Milsome, J. R., M.D., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer to the Fever Hospital, Chertsey.

Murphy, J. J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to Dublin City Commercial Club.

Owen, I., M.A., M.B., M.R.C.P., has been appointed Lecturer on Materia Medica to St. George's Hospital.

Ritchie, J., M.B., M.C., F.R.C.S.Ed., has been appointed Surgeon to George Heriot's Hospital, Edinburgh, vice Wood, deceased.

Roper, W. R., M.A., L.R.C.P.Ed., L.F.P.S.G., has been reappointed Medical Officer of Health for the Newmarket Urban Sanitary District.

Sealy, W. B., L.R.C.S.I., L.S.A.D., has been appointed Medical Officer for the Broughton District of the Newark Union.

Wilson, C. W., M.B., M.R.C.S.E., has been appointed a Consulting Surgeon to the Cirencester Cottage Hospital.

Births, Marriages, and Deaths.

BIRTHS.

Blackett.—On the 15th inst., at Wangford, Suffolk, the wife of Edward R. Blackett, M.D., of a daughter.

Irvine.—On the 18th inst., at Alladale, Woolston, Southampton, the wife of Dr. Gerard J. Irvine, Royal Navy, H.M.S. *Hector*, of a son.

Lidderdale.—On the 20th inst., at East Hayes, Cheltenham, the wife of Robert Lidderdale, M.D., Sanitary Commissioner for Bengal, of a daughter.

Roberts.—On the 19th inst., at Upper Rathmines, Dublin, the wife of Browne Roberts, M.D., of a son.

Whitlock.—On the 23rd inst., at The Limes, Linton, Cambs., the wife of J. E. N. Whitlock, Surgeon, of a daughter.

MARRIAGES.

Birch—Boschetti.—On 16th inst., at the Parish Church, Eccles, Philip Birch, M.R.C.S.E., of Cromwell House, Stockport-road, Manchester, to Ida Agnes, youngest daughter of the late John Newbery Boschetti, Esq., of Eccles.

Mackenzie—Gordon.—On the 22nd inst., at St. Mark's, Notting-hill, Surgeon-Major John Mackenzie, M.D., Army Medical Department, to Ashton Bostock, only daughter of Surgeon-General C. A. Gordon, M.D., C.B., Honorary Physician to Her Majesty the Queen.

Potts—Rhodes.—On the 17th inst., at the Parish Church, Beckenham, Lawrence Potts, M.R.C.S.E., L.S.A.L., of Leatherhead, second surviving son of the late Robert Ullock Potts, of Beckenham, to Edith Mary, elder daughter of John G. Rhodes, of Beckenham.

Spence—Bennett.—On the 23rd inst., at St. Matthew's Church, Redhill, by the Rev. H. Brass, Incumbent, James Beveridge Spence, M.D., Medical Superintendent, Burntwood Asylum, near Lichfield, to Elizabeth Roebuck, eldest daughter of Richard Bennett, Esq., of Redhill, Surrey.

Tomlinson—Druitt.—On the 17th inst., at St. Nicholas', Chislehurst, William Winslow Tomlinson, Surgeon-Major, Army Medical Department, to Anne Maud Mary, only surviving daughter of the late Robert Druitt, Esq., of Stoke Newington.

Wodsworth—Townshend.—On the 14th inst., at Queenstown, Ireland, Charles Gregory Wodsworth, Staff-Surgeon, Royal Navy, to Emma, daughter of the Rev. T. W. Townshend, formerly Vicar of Inistiogue.

DEATHS.

Bennett.—On the 16th inst., at George-street, Devonport, James Bennett, M.R.C.S.E., L.S.A.L., aged 64.

Bevan.—On the 18th inst., at Rye-lane, Peckham, George William Bevan, Surgeon, formerly of St. Ives, Cornwall, in his 79th year.

Bogg.—On the 13th inst., at his residence, Burlington-villas, Altrincham, Thomas Wemyss Bogg, M.B., M.R.C.P., aged 44.

Cryan.—On the 17th inst., at Rutland-square West, Dublin, Robert Cryan, F.K.Q.C.P.I., Professor of Anatomy and Physiology in the Catholic University.

Handyside.—On the 21st inst., at Lansdowne-crescent, Edinburgh, Peter David Handyside, M.D., F.R.S.E., Lecturer on Anatomy, Royal College of Surgeons, Edinburgh.

Henderson.—On the 12th inst., at Keith, J. L. Henderson, L.R.C.P.Ed.

Hurman.—On the 17th inst., at Eastover, Bridgwater, H. B. Hurman, M.R.C.S.E., L.S.A.L.

Sanders.—On the 18th inst., at Charlotte-street, Edinburgh, William Rutherford Sanders, M.D., Professor of General Pathology in the University of Edinburgh.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, Feb. 28.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Cetacea."
MEDICAL SOCIETY OF LONDON.—8½ P.M. Mr. Thomas Bryant will show the Patient from whom in November last he removed the Head, Neck, and Half the Shaft of the Femur for Acute Necrosis, and in whom new bone and joint have been reformed.—Dr. Heron will show a Case with Ataxic Symptoms and Marked Knee Phenomenon.—Dr. Woakes, "On the Treatment of Goitre by Fluoric Acid."

Tuesday, March 1.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 3 P.M.
ROYAL INSTITUTION.—3 P.M. Professor Edward A. Schäfer, "On the Blood."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

A NEW HOSPITAL IN CHINA.

THE *North China Daily News* reports the details of an interesting ceremony at Tientsin on December 2nd. It appears that in 1879 the use of a portion of the memorial temple to Tsêng Kuo-fan in Tientsin was granted to Drs. J. K. Mackenzie, Irwin, and Howard, of the American Episcopal Methodist Mission, on account of valuable medical services which had been rendered by them to a relative of the Viceroy and to General Chow. This building served as a "dispensary," to which the natives flocked in large numbers to obtain relief from their ailments. Various inconveniences, chiefly distance from the settlement, were, however, experienced in connexion with these premises, and it was proposed to erect a hospital for in-patients on a portion of the London Mission compound. This project has now been carried out, principally by means of funds supplied by the Viceroy and other wealthy Chinese, and the opening of the hospital, in presence of the chief officials, native and foreign, formed the ceremony referred to above. The building is in the style of a Chinese temple, whilst the interior arrangements have apparently been planned as far as possible in accordance with Western ideas of comfort and efficiency. We cannot but wish success to an enterprise which must prove a means of extending the benefits of European medicine amongst the Celestials.

Dr. John Aikman.—We could not express an opinion without hearing both sides of the question.

A General Practitioner.—There is much truth in the remarks offered, but they relate to points scarcely arising out of the question under discussion.

Dr. Pittock.—The paragraph is unworthy of notice.

Surdus.—We are unable to give the information desired.

Mr. John Davies.—The first and third articles specified are surgical; the second, doubtful.

SMALL-POX AND VACCINATION.

To the Editor of THE LANCET.

SIR,—I notice in your correspondents' column an answer to "Inquirer" on the subject of small-pox. I have thirty or forty copies of my paper on Small-pox and Vaccination at the service of any medical man who would like a copy, and would send one free to any applicant.

I am, Sir, yours faithfully,

WM. TIFFIN ILIFF.

Kennington-park-road, Feb. 22nd, 1881.

ON THE EFFECTS OF IMPURE MILK UPON CHILDREN.

To the Editor of THE LANCET.

SIR,—Since the discovery by Dr. Ballard that milk contaminated with sewage water caused typhoid fever, the attention of the whole profession has been directed to the subject, and there is little doubt that many other affections are produced from the same cause. If these few observations direct the attention of my medical *confrères* to this important subject, my investigations will be amply repaid.

In 1869 there were no less than eleven cases of follicular stomatitis in one sub-district of this town; five were under my own care, and four under the charge of the late Mr. Burns. We examined each other's cases, and on investigation I found that four of the cases under my own charge and two of those under the late Mr. Burns were all supplied by one farmer, whose cattle were suffering from the foot-and-mouth disease, and the remaining five were supplied by a milkseller, one of whose cows was suffering from the "gargles," as it is popularly termed, which, I may explain, is simply an inflammation of the lactiferous tubes of the teat, through which it is difficult to milk at the first onset, and the teats mostly bleed when the dairyman first begins to milk a cow so affected; very often a tube is used to open the ducts, but whatever procedure is adopted, oftener than otherwise the cow loses that "quarter." This is a species of "Aden-emphraxis" (εμφραξις, stoppage). It can be easily understood by anyone who has not seen such a case how the milk is rendered impure by an admixture of blood, &c. I have not been able to secure such a sample of milk since my attention has been directed to it, or should have very much liked to have had an analysis made. Several of my friends (veterinary surgeons) have promised to apprise me when they had a case under their care, but they all state that these cases are generally kept very secret, and that all cowkeepers and farmers imagine that they can treat them themselves successfully. I will defer any further remarks until after considering the next class of cases.

Diphtheria.—Last year two cases of this disease came under my notice, and my attention was drawn to the milk, as both cases were supplied from the same "shop," and on inquiry I visited the farmhouse from which it came, and a more disgracefully dirty place never before fell to my lot to visit. The pigstyes were adjoining the dairy; the milk utensils were brought home closed up and not washed out until the night's milk was brought into the town. One large can I opened smelt very offensive. Last September two deaths occurred in this town from the same cause, and on inquiry I found that the milk supplied came from a farm some two miles away. On visiting it I found that all the milk utensils were washed in water from a pump impregnated with sewage. The following is an analysis of the water, kindly made for me by the borough analyst, clearly showing how the milk was contaminated:—

Analysis.—Total solid residue, 20 grains per gallon; total chlorine, 1·1 grain per gallon; nitrogen as nitrates and nitrites, 4·5 grains per gallon; free ammonia, ·054 parts per million; albuminoid ammonia, ·24 parts per million. The above sample of water is decidedly unfit for drinking purposes, as there is evidence of serious contamination. By the above data it would appear that the source of contamination has been removed, but the evil effects are still present in the sample.

First, as to the usefulness of this letter. Anyone might say "one swallow does not make a summer"; quite true, but it directs the attention of the whole profession to the subject, and where a case of stomatitis occurs first obtain a supply of milk from another source. This is the first step in the treatment, and it is really remarkable how soon an intractable case becomes amenable to curative measures, as often the simple cases run on to the more malignant forms of noma, and if anyone is able to carry my investigations still further they will have done some good.

On inspecting premises, after many years' experience, I have scarcely ever been able to find a sufficiently insanitary condition on the spot to have been the cause of the outbreak in the case of diphtheria; but during the last two years I have always been able to find that the inmates of the house where a case has occurred are invariably supplied with a bad quality of milk. Now, the important lesson to be learnt is that all local authorities should obtain their supply of milk for analysis not from the shopkeepers, but from the little farmers who bring milk into the town, and when it is found impure the information should be given to the rural nuisance inspector, so as to enable him to visit the farmhouse whence it comes, and ascertain the purity of the water upply.

I have lately taken to painting the tonsils and all the parts affected with the diphtheritic exudation with a solution of carbolic acid, tincture of iodine, and tannate of glycerine, and it is marvellous how, after three or four applications, the exudation is scarcely ever renewed. The constitutional symptoms can scarcely ever be treated in the same way. Some cases improve under iron, some require bark or quin. disulph., but the *sine quâ non* is the swabbing of the tonsils with the aforementioned paint. Under this treatment I have never lost a case.

I am, Sir, yours, &c.,

J. S. WALKER, M.D. St. And., F.R.C.S.E.

Staffordshire, Jan. 1881.

DESQUAMATION AND INFECTION IN SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—The medical attendant of the college where my son is a student having noticed my correspondence under the above heading, published in your issue of the 12th inst., I must ask your kind indulgence to give publicity to this letter. My acquaintance with the medical attendant in question is of the very slightest, as I only spoke to him on one occasion for about five minutes in reference to this illness, when I found him courteous and sympathising, and my son testifies to having received every possible personal attention from him, and I mention this to show that no unfriendly feeling influenced me in what I wrote. I wished either to be corroborated or contradicted by medical authorities in the opinion I entertained, that this gentleman had made a mistake in allowing his patient to leave the infirmary and pronouncing him free from all risk of conveying infection three weeks after an attack of scarlet fever, no matter how slight, and more especially where no desquamation of the cuticle had taken place before he left this gentleman's care.

Dr. David Page, to whom I feel much indebted for giving me, through your columns, his opinion and the benefit of his experience, fixes eight weeks as the soonest to permit, with safety, any scarlatina patient to mingle with the healthy. Other medical authorities have fixed the same time; some have suggested six weeks, and this has been the shortest date named to me, but when I mentioned three weeks not one of the many medical gentlemen I have spoken to have said otherwise than that no possible inducement could make them receive a patient recovering from scarlet fever inside their own doors after such an unduly short isolation. Being a layman myself, I only now learn for the first time that in slight attacks of scarlet fever desquamation of the cuticle is generally delayed, but surely I must assume that the medical attendant of the college was not ignorant of this well recognised characteristic, which should of itself, I humbly submit, have made him act with more caution. This gentleman takes credit to himself "that no persons have suffered from my son's presence among them," and that "he showed a due regard for the health of the boy and the safety of the public." I must remind him that it scarcely admits of a doubt, but that this satisfactory result is entirely attributable to my having, at the instigation of numerous friendly medical acquaintances, acted in total disregard of his advice. I did not bring my son home at the time he said I might do so without the slightest risk, having other children who have never had this fever, nor did I send him elsewhere where he could have spread infection, but I isolated him in an infirmary conducted specially for receiving similar cases. What the result would have been if he had been at large in a school of two or three hundred boys when desquamation of the cuticle was taking place is too awful to contemplate, and I think the medical attendant and all those interested in the college, including the parents of the pupils, ought to feel very much indebted to me for the fortunate prudence I exercised. The most important portion of the letter of the "Medical Attendant at the College" is the concluding paragraph, which does not concern myself. I leave to the gentleman of high standing in his profession to whom it refers to defend himself from the imputations conveyed in it. First of all, there is a distinct doubt thrown out as to any desquamation whatever having been really discovered, and then it was suggested that it was eczema. All I can say is that I myself entertain far too high an opinion of the professional abilities of the gentleman alluded to, whose services I availed myself of, to think him for one moment capable of committing such grave and unpardonable errors; but let him speak for himself.

I remain, Sir, your obedient servant,

Feb. 22nd, 1881. ENQUIRER.

To the Editor of THE LANCET.

SIR,—Will you allow me to state that the desquamation to which attention was called by the nurse of the patient, and for which my advice was sought, was confined to the palms of the hands and the soles of the feet, in the latter case the cuticle coming off in somewhat large pieces. I saw nothing to justify the suspicion of eczema, and have no doubt whatever in my own mind that the scarlatinal poison was the cause.

I am, Sir, yours faithfully,

Feb. 21st, 1881. THE MEDICAL MAN WHO SAW THE DESQUAMATION.

To the Editor of THE LANCET.

SIR,—Will you allow me, through your columns, to tentatively express an opinion which has for a long time been forcing itself upon my mind, that the accepted ideas of our profession as to the connexion between desquamation and infection in scarlet fever are probably most unsound.

Although occasionally occurring in other eruptive fevers, desquamation is undoubtedly one of the most remarkable and characteristic phenomena in scarlet fever, and, so far as it is generally coincident with the infectious stage of the disease, is a most valuable indicator. Beyond this I certainly do not think that the cast-off epithelial débris has any special significance over other excrementitious matters either as retaining or distributing infection. I should hesitate to say that the infective element of scarlet fever might not be present in any of the excretions, but it is my experience that, as the alvine excretions are specially important as regards the infection of typhoid fever, so the excretions from the throat as distributed by the saliva and the breath are specially important as regards the infection of scarlet fever.

It is in accordance with my experience in scarlet fever that, whilst on the one hand infection may be communicated before desquamation has commenced, or in cases where this symptom has not been noticed at all, on the other hand desquamation subsequent to and dependent upon an attack of scarlet fever may exist long after all danger of personal infection from the patient has ceased. This is a matter of very great practical importance, if for no other reason than that in proceedings before courts of justice for wilful exposure of persons suffering from scarlet fever evidence of desquamation at the time of exposure has, as a rule, been held to be sufficient proof of the infectious condition of the person at the time.

I am, Sir, yours, &c.,

Shrewsbury, Feb. 16th, 1881. W. N. THURSFIELD, M.D., &c.

To the Editor of THE LANCET.

SIR,—Some time since I received a circular from the Royal College of Physicians requesting details from personal observation of cases of scarlet fever. Cannot the College, from the accumulated experience it must have received, throw some definite light upon the case under discussion in your valuable pages?

It seems to me that the desquamation from such a very mild attack as the case in question would be almost unnoted. If we are to expect desquamation from such a case to occur at the end of six weeks, we are forced to the conclusion that the lighter the fever the more prolonged is the risk of infection.

Dr. Wilson, in his "Hygiene," says: "The question of quarantine must be decided by the special case." Must we add, "the lighter the case the longer isolation." I have not had an opportunity of reading Dr. Page's pamphlet, but in the typical case he quotes desquamation occurred five (not six) weeks after the commencement of the illness. If we are to isolate our mildest attacks of scarlet fever three months (a conclusion which might be easily deduced from Dr. Page's remarks), who can prevent the spread of scarlet fever, especially amongst the poorer and more numerous class of patients? unless, indeed, some philanthropic individuals should supply the families and others coming in contact with the infected person with glycerine to anoint their bodies and bottles of ice-cold water, to be held a little before the mouth, as recommended by Mr. Wynter Blyth. (*Vide* THE LANCET, Jan. 8th, 1881.)

I am, Sir, your obedient servant,

Lambeth, S.E., Feb. 21st, 1881. F. J. ELLIOT.

To the Editor of THE LANCET.

SIR,—The opinion enunciated in a letter in THE LANCET of to-day by Dr. Page of Kendal, and, I believe, shared in by most practitioners at present, as to the length of time it is necessary to isolate scarlatinal patients, seems to me likely to lead to so much unnecessary trouble and injury, that I think I ought to contribute my mite towards amending it by asking you to insert among the correspondence in your journal this statement. That, according to my experience, three weeks is sufficiently long to isolate a patient with scarlet fever, whether desquamation be going on at the end of that time or not, if the following plan have been adopted—viz., to smear the entire surface twice a day with olive oil containing a fortieth part of carbolic acid, and to give a hot bath and a scrubbing with soap three times during the last week, immediately after the last one the patient leaving his room and getting into clean linen and a clean bed. My experience of this plan has extended to many instances, and I have not known it fail, though in some cases tested severely. Nay more, I have good reason for thinking that the inunction, thoroughly and carefully carried out, will prevent the spread of the contagion during the course of the fever, for in two instances it did not spread, although there was the closest and most continuous communication between the patient and numerous children who had never had the complaint.

I am, Sir, yours obediently,

Mare-street, Hackney, Feb. 19th, 1881. E. G. GILBERT.

MEDICAL REFORM.

To the Editor of THE LANCET.

SIR,—I have read with some interest your article in THE LANCET of Jan. 22nd in favour of a Conjoint Examining Board. Your proposal to abolish three of the existing Boards is so far good, and one to which few objections can be urged. As a licentiate of one of those corporations I may, however, be permitted briefly to point out some of the claims which that body has to be at least heard in its own defence.

The Faculty of Physicians and Surgeons has no need to apologise for its origin or hitherto for its existence; incorporated before the Royal Colleges of Edinburgh, it has done much to encourage medical research, and still more to maintain a cordial and becoming feeling between members of the profession in Scotland. With regard to the examination for the diploma, as a matter of fact it is more comprehensive and eminently more practical in character than that of either of the Royal Colleges of Surgeons, including clinical medicine, a subject not insisted on by those bodies. As to the laxity in passing candidates, I am convinced it is more imaginary than real, as English and Irish students who come up frequently find out to their cost. We hear now and again of some men having passed after being rejected at several other Boards, but such instances prove very little, as the candidate may have improved since his previous appearance.

So far, then, your proposal is all very well, but a great deal more is wanted than the mere abolition of a certain number of the present Examining Boards; such a measure of reform as will obviate the scandal and disgrace of hundreds of men being annually admitted into the profession, and eligible for registration as general practitioners, who have never undergone an examination in two such all-important branches as midwifery and clinical medicine. In conclusion, I would humbly recommend some of your ardent reformers to remedy the evils that exist at their doors before going so far afield to seek abuses. Reform, like charity, should begin at home.

I am, Sir, yours obediently,

Feb. 1881. X.

LIGATURES.

A Surgeon.—A succinct account of the history of the use of ligatures for the arrest of hæmorrhage appeared in The Lancet for Dec. 15th and 22nd, 1877, entitled "The Battle of Ligatures."

Dr. M. V. Pierce is thanked, and will receive a private note.

P. J. has forgotten to enclose his card.

Mr. C. S. Redmond.—The assumption of false titles is clearly illegal, but there is no legal test of qualification in midwifery; anybody may practise it, and the bold and the ignorant are too apt to escape with impunity.

THE MORRIS RELIEF FUND.

To the Editor of The Lancet.

Sir,—Will you kindly insert in your forthcoming number the following complete list of contributors to the above fund since the date of my appeal of Feb. 3rd, and oblige, yours very truly,

Ewell, Surrey, Feb. 22nd, 1881. Geo. R. Barnes, M.D.

	£	s.	d.
A Surgeon	£5	0	0
Per G. R. Barnes	4	10	6
Dr. Tuckwell, Oxford	3	3	0
T. Harley, Esq., Haverstock-hill	1	0	0
Dr. Bull, Hereford	£1	1	0
A. Steadman, Esq., Great Bookham	1	0	0
W. Y. Marten, Esq., Walkden	0	6	0

FEES FOR ATTENDANCE ON ODDFELLOWS.

To the Editor of The Lancet.

Sir,—I have to thank those who have kindly replied to my query on the above subject. I find from numerous private communications that five, six, and seven shillings per annum, with 2*s.* 6*d.* for examination, are by no means uncommon fees, and in country districts where the patients are scattered, these sums are certainly not excessive.

I am, Sir, yours faithfully,

Ben Regis, Feb. 23rd, 1881. F. D. Lys.

Enquirens.—1. Occasionally, when their services are required.—2. No. 5, York-buildings, Duke-street, Adelphi, W.C.

Mr. Simeon Snell.—In an early number.

Mr. Moxhay (Reading).—The paper has been received, and is marked for insertion.

Dr. Speirs (Haltwhistle).—The paper will appear in an early number.

The publication of *Mr. Spencer Watson's* letter is unavoidably deferred till next week.

KOUMISS.

To the Editor of The Lancet.

Sir,—During the discussion following Dr. Sutherland's paper on Koumiss at the Clinical Society on the 11th inst., inquiry was made by whom the koumiss used in his case had been supplied. May we ask you to state in your next issue that it was so supplied by your obedient servants, E. Chapman and Co.

Duke-street, Portland-place, W.

"CHLORAL LABOUR."

To the Editor of The Lancet.

Sir,—"A Subscriber, M.D.," asks a question in your publication of Feb. 12th as to the use of chloral in labour. I have found chloral of the greatest use, both in reducing the acuteness of pains (though not diminishing the propulsive power), and especially in cases of rigid os uteri. I have known several cases where after hours of labour, the os remaining rigid, two doses of ten grains each, given within half an hour of each other, have been followed by immediate relaxing of the os, and regular powerful pains. I have followed the suggestions given by Dr. Playfair in his book on Midwifery.

Clapton, Feb. 1881. Gerard Smith, M.R.C.S.

Surgeon, &c.—English diplomas entitle their holders, so far as the licensing authority is concerned, to practise in the United Kingdom and all its colonies and dependencies. But in some colonies, as in Canada, there is a colonial medical law requiring registration in the colony, to which a small fee is attached.

Mr. A. Goldney Chitty.—If our correspondent can send us published reports of the facts, we shall be glad to have them.

Communications, Letters, &c., have been received from—Dr. George Johnson, London; Mr. Mason, Pontypool; Mr. Gilbert, London; Mr. J. Smith, Haxby; Mr. W. MacCormac, London; Mr. E. Kennedy, Gorton; Mr. Cæsar, Shirley; Mr. Croft, London; Messrs. Beynon and Co., Cheltenham; Dr. Herman, London; Mr. R. Torrance, Newcastle-on-Tyne; Messrs. Bacon and Co.; Messrs. J. B. The above Scale of Charges is arranged upon the basis of the classification adopted in the Index.

Notice.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "The Lancet General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in The Lancet.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.

The postal arrangements relating to the distribution of The Lancet will be considered from time to time in the interests of subscribers.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

Presidential Address

ON

MEDICAL EDUCATION IN RELATION TO OBSTETRICS.

Delivered before the Obstetrical Society of London, March 2nd, 1881,

BY J. MATTHEWS DUNCAN, M.D., F.R.C.P. ED.,
PRESIDENT OF THE SOCIETY.

GENTLEMEN,—I have great pleasure in thanking you for the very high honour you have conferred upon me by placing me in this chair, a position which has acquired biennial increments of eminence from the well-deserved renown of the great physicians who have successively occupied it, and not least from that of the last President, Dr. Playfair, the author of valuable laborious monographs, and of a popular textbook, an esteemed teacher, and a famous practitioner. We are grateful to him for the time and labour he has given us, and I can only hope to emulate him in these respects as well as in his urbanity and gentleness.

The best honours in medicine are conferred by professional brethren, our peers, who alone are competent judges, who alone, indeed, know us. But I dare not rate my present position without deeply feeling that proportionate to the honour are the responsibilities and the duties. To take my allotted share in the mere business of this great and prosperous Society is not a heavy undertaking, but the other and less prominent duties of my position are really onerous —to preside, to direct, to encourage, to repress; to do all this in the proper spirit and in a manner that cannot be misinterpreted. I shall try, in reliance on your generosity and kindness and support, to keep unbroken the good reputation, as a Society, which we have hitherto maintained.

This Association has been and continues to be prosperous. Its membership is very numerous, its exchequer well replenished, its meetings well attended; above all, its proceedings are interesting and its annual volume of Transactions replete with valuable matter.

In the proceedings of our ordinary meetings we include addresses, discussions, demonstrations, papers. These last are various in character, narration of experience, curious or rare or instructive cases, new remedies, new instruments, and the results of observation and research. In the Council and in committees, besides the arrangement of business, much useful work is done of a political or semi-political kind; and I shall follow a precedent, which seems a good one, in devoting the few remarks I propose to make to some important and interesting political matters.

This Society has already interfered powerfully, and with advantage to the public interests, in various medico-political affairs, and there are some measures, especially that relating to the education and registration of midwives, which it has already done much to promote. In the present state of the conduct of legislation we can have little hope of success in Parliament, unless we secure the approval and active operation of a Minister of State, and in this we should probably have no difficulty if we could make for the Minister a quiet political bay in the busy and often turbulent session. We do not wish for our affairs the Parliamentary prominence of party questions, and we have no means of quickly convincing our legislators of their very great importance. We have therefore reluctantly to submit to the patient waiting for a more convenient ministerial season, a time of which we at present see no immediate prospect.

Before proceeding, however, I must devote a few sentences to explain the kind of importance to be attached to the political proceedings of this Society. Their place in the first words I address to you might be supposed to indicate that the Society claims for them a position paramount, and this would be a very great mistake. The Society knows well that political interference is a mere accident of public utility arising from the position it has otherwise attained. The great work of this Society is not political. It is not initiated nor fostered by Ministers of State, and it would be fatal to our best interests to wait upon such uncongenial influence. Obstetrics and gynæcology have been advanced to their present eminence and power and usefulness exclusively by the labours of comparatively humble medical men. As it has hitherto been, so in the future it must be. If we look to the gradual progress of our department of medicine, we observe little else than a series of scientific papers bearing the names of our obstetric heroes. A great practitioner distinguished for learning, sagacity, and power may for a time maintain posthumous fame; but for the most part practitioners and practices, books and instruments, have been lost in oblivion. Imperishable remain the small scientific papers that have taught us, and will teach all future medical students, the anatomy of the pelvis, the anatomy of the gravid uterus, the anatomy and physiology of the unimpregnated female, the mechanism of natural delivery, obstetric auscultation, obstetric anæsthesia, the mechanism of unnatural delivery, and others too numerous to mention here. The wisest judges of our Society will pay but scant attention to our political proceedings, and so also will our best members. The basis of our prosperity and greatness is the unobtrusive memoir embodying thought and work, and recording distinct results; and we must admit that such papers are often dreary affairs, as they are languidly read to benches not overfilled. The man who sends us such, generally a young man, must not be discouraged; his paper will command wide recognition, and, although worldly esteem and prosperity are but secondary objects in his view, his good work will be, as long as he lives, an increasing force tending to his promotion in these respects. It is enough to say of him, "He was the author of that." This Society will pay due attention to its political work as it arises, but it must devote its best energies to its scientific work. With the amount and quality of this it may be pleased, even delighted, but it can never be satisfied. Scientific appetite and greed grow with the food supplied. Every new contribution widens the prospect, and increases the demand for yet more.

Much interest has been, and is now, widely expressed and widely felt in the improvement of the medical curriculum, and our department of the profession is indebted to our late president and to Dr. Macnaughton Jones for their enthusiastic advocacy of its claims. With especial force is it insisted that the course of midwifery lectures required by the Corporations is inadequate, and while on this point there is, so far as I know, no difference of opinion, I am sure that, in the whole matter, we have the sympathy of all men of progress. In considering it, the distinction should carefully be maintained between the theoretical and the practical, between what is desirable and what is feasible and attainable; and this is not always done. For instance, it is common to say that from every student there is, or there should be, required evidence of a thorough knowledge of this or of that, and, among others, of midwifery and the diseases of women and of newly born children. Now, it is only a very moderate amount of knowledge that is now or ever will be required, and it is in vain to aim at more. It is not necessary to have experience at examining boards to get assurance of this, for, after more than thirty years of unceasing study and practice, my own knowledge of the subjects is anything but thorough.

It is a moderate amount of elementary knowledge that is required of a candidate for licence, and he is expected, nay, in duty bound, to cultivate it so as to produce the maturity of a good general practitioner. Within a limit of forty lectures it is impossible for the teacher to give a good introduction to the elements of his subject; and yet it is not to be forgotten that the best teacher is he who condenses most successfully—who, knowing what is essential, what is of high importance, fixes on a well-arranged and, if possible, a consecutive series of facts and principles, and carefully indoctrinates his pupils in them. In any other sense a complete course is not desirable. Our lecturers should be neither schoolmasters nor grinders.

The history of teaching surely indicates that in this matter we shall in due time get what we want. If we are true to ourselves and increase the science, room will be found for the teaching of it. Our glorious ancestors, Smellie and William Hunter, taught midwifery and women's diseases from love of, and respect for, the subject, as those teachers do now who give far more than the curriculum requires, and so it will always be. Smellie's and William Hunter's courses were not required by the licensing or analogous boards of their day, and they probably never reached the length of twenty lectures. We have got far beyond this, having compulsory courses, which in some schools must reach one hundred lectures—compulsory actual practice of students, clinical teaching and lectures, and instruction in instrumental delivery.

In settling what should be our demands in respect to compulsory attendance on lectures, we must consider our position in relation to medicine proper and surgery proper. The solidarity of medicine, surgery, and midwifery is a popular and a true argument, and justifies our claim to equal honour and consideration for the three branches. But while this claim is now at length, thanks to the unaided achievements of obstetric science, undisputed, it does not follow as a consequence that equal time should be allotted to the teaching of the three departments. Medicine and surgery are each larger than our department. They were taught systematically before midwifery; and, as a result of this historical fact, their teaching embraces large and important subjects, such as the doctrines of inflammation and fever and injury, which, though obstetrical as much as they are medical or surgical, yet are not uselessly repeated in courses of midwifery, being left in those older departments of teaching to which ours is an addition.

But the points to be regarded in this somewhat complex subject are not exhausted. Time is short, and we must reflect on the age to which we would have a medical student's education prolonged. The curriculum requires a period of about four years, and is already so filled that more can scarcely be crammed into it. Without an extension of the curriculum to five years, it appears to me vain to hope for a thorough and fair rearrangement of the various times allotted to the various courses; and such an extension is a matter for very full consideration, with a view to the interests, not of students only, but of the State also. It is not a mere mechanical question — so much time available, so much attendance on lectures possible; for it has been widely asserted, and with some show of reason, that our present extended curriculum is a failure, not only not yielding results in proportion to the extension, but producing only increase of cram and dangerous pretence of knowledge. With this view I do not coincide, but it puts in a clear way the evils attendant on attempting too much. When we increase the curriculum, we must consider not only the time available, the age to which the study should be prolonged, but also the digestive power of the average student's mind. The production of pedantry is to be shunned.

As members of this Society we have observed with deep concern those discussions in the Medical Council which relate to the place, in the education of our medical practitioners, accorded to physics and chemistry, and we cannot hesitate to express our sympathy with those who wish for these branches of science a paramount position among the not purely professional. For Greek or Latin, we have no special reason to contend, because the obstetrician or gynæcologist has never occasion to make use of them, unless for some purely literary, not scientific or practical purpose. Although it may well be asked, What interest have the legal guardians of the education of our practitioners in Greek or Latin? it may, on the other hand, be confidently asserted that their place and power in the higher education of all men need no defenders—no supporters. These languages are not necessary for a medical practitioner, and this cannot be said of physics and chemistry. As obstetricians or gynæcologists we can neither comprehend what has been achieved in the past, nor can we have any hope of future progress without the aid of the latter. Latin and Greek may be said truly to have much the same place in higher general education as anatomy has in medical education; for through them pass the roots of our language, our philosophy, our arts, and our sciences. But while high culture cannot exist without Latin and Greek, excellent practitionership, such as the Medical Council has to care for, may flourish without them. Latin and Greek will always be studied by the highest class of medical men, and will always command an equivalent return of power and influence, and even of the gross reward of money. Physics and chemistry must be studied by all good medical men, and knowledge of them is a guarantee of good practitionership.

Were this a proper occasion, I might enter at length on the history and the present bearings of this important matter, but I shall confine myself to a very few historical remarks which may encourage the supporters of what we regard as indisputably the best direction of medical legislation. Even anatomy was once in the insecure and neglected position in which physics and chemistry now are.

Although physics and chemistry are not depreciated or lightly esteemed, their supporters have still to struggle to secure for them their proper place, and medical history points surely to their still further rising importance in medical education. The problem was well understood and the conflict stoutly maintained a century ago, and the too successful ringleader then was the great Stahl, who, while he despised and opposed anatomy, fought ardently against the introduction into medicine of mechanical and dynamical theories, and, upon the whole, Stahl gained the day—that is, he in this matter carried with him the majority of great medical men. Truth, however, is invincible, and in spite of Stahl and his followers, opposition to mechanical, chemical, and dynamical theories has gradually become less and less, till now the whole of the psychical school is extinct or survives in defence of the comparatively very narrow influence of what are now called vitalist doctrines. Of these profound doctrines and of their great supporters we speak only with unqualified respect. Their existence and extensive power as now exercised are in no manner a protest against the great and due influence of physics and chemistry.

So great has been the progress of physical, chemical, and dynamical theories in obstetrics and in the other branches of medicine, in our own days, that it is necessary still further to explain historically the reluctance, even now, to admit their rising power and utility. Most of us here, at least most of those who have even a few grey hairs, and most of the members of our Medical Council, were reared under the potent empire not of Stahl, but of theories more or less exclusively metaphysical like his. Not a few of us imbibed our first lessons in medical science at the feet of the venerated Alison, the greatest medical philosopher of his day; and as we love the memory of the man, we are slow to disparage any part of his teaching. Yet his teaching—that is, what was instilled into us so recently—is already so obsolete in kind, though not antiquated by mere lapse of time, that you will scarcely believe that these are his words:—"When we compare," says he, "the general notions as to medical science which are prevalent at the present day with those which are recapitulated by Dr. Cullen in the Introduction to the last edition of his First Lines as holding their place up to his time in the schools of medicine, the most important observation that occurs to the mind is the present general, although not always avowed, recognition of this principle,—that the phenomena of disease, like all other phenomena of living bodies, belong to a class of facts, and constitute a subject of investigation altogether distinct from those which are presented by any forms or changes of inanimate matter. Dr. Cullen states that 'the mechanical philosophy had been applied (soon after the discovery of the circulation) towards explaining the phenomena of the animal economy, and continued till very lately to be the fashionable mode of reasoning on the subject;' and he very properly admits that it must 'still in some respects continue to be applied,' but he adds that 'it would be easy to show that it neither could, nor ever can be, applied to any great extent in explaining the animal economy.' Now an important step," Alison continues, "has been already made in the progress of medical science, when this proposition has received the general assent of the profession, and when the study of Mechanical Philosophy is recommended to the student of medicine, not as one of the foundations of medical science (with the exception of a few simple applications of its principles in some parts of physiology), but simply as an example of successful investigation. A nearly similar observation may be extended to the subject of Chemistry, for although it be true that all vital actions are attended by, and in part dependent on, a series of continual chemical changes, and although a certain knowledge of chemical principles is therefore required of the physiologist, yet the chemical changes of animated nature are so distinct from those which we produce at pleasure in dead matter, as the stimulation by nerves and the contraction of muscles are distinct from any of the principles and powers of mechanics."

If physics and chemistry were in this slighted state forty years ago, and have now risen to jostle Greek and Latin in their time-honoured places, what may we not expect from the progress of science within another forty years? There is no reasonable doubt of their growing into pre-eminence, and it is to be hoped that they will not treat rudely the study of these languages, which are the favourites of all that are scholastically disposed. For physics and chemistry we ask no favour, only justice, at the hands of our Medical Council.

The registration of disease is, as you are aware, making great progress in isolated parts of the country, and its universal adoption may be expected in no long time. Before this time comes, imperial legislation may compel it; and it is almost certain that further legislation with a view to prophylaxis will be a valuable fruit of the increased knowledge provided by the system. There are many ways in which such prophylactic legislation may interest us; and it is in the highest degree imperative to prepare for it, and to watch it, so as to have the laws wisely framed for the public good. Puerperal fever will, no doubt, be the chief class of diseases in our department for prophylactic legislation; and it may be expected that we shall be able to give decided testimony as to the value of our plans. Antiseptic cares are already in some parts of Germany required by law or recommended to midwives by those who have a legal right to command them; and it is to be remembered that in that country almost the whole of midwifery is in the hands of midwives.

It is evident that in this country we have been passing through a period of alarm allied to panic, arising from newly acquired knowledge of the greatness of the evil and ignorance of its nature and mode of propagation. This prolonged panic has naturally led to extravagant views and to grave injustice, especially to midwives and to hospitals. Obstetric science is gradually disclosing the nature and prevalence of the diseases classed under the name of puerperal fever, and this work has been done chiefly under the guidance of those antiseptic theories which have produced such grand results in medicine and surgery as well as in midwifery. It is to antiseptic theories also that we owe our most trusted resources in practice—resources whose value is demonstrated beyond all doubt, and which will soon, I believe, be so generally adopted as to command the consideration of those interested in prophylactic legislation.

But I wish, at this early time, to put in a plea for another prophylaxis, the legislative protection from syphilis, especially of women about to be married and of doctors. It is not rare to meet with instances of carelessness on the part of bridegrooms so gross as to merit the imputation of criminality; innocent women being, as a result, infected with syphilis, and thereby killed or maimed for life, and their offspring in a like terrible plight. No doubt such tragedies are sometimes enacted in spite of due care on the part of the husband; but many are the result of culpable thoughtlessness or culpable neglect. Again, in my own medical circle I have lost, through accidental surgical infection with syphilis, several medical brethren whose lives were very valuable. One of them, an accoucheur, did not survive attendance on a syphilitic lying-in woman above a year and a half. Now, it appears to me that such proceedings as the marriage of a man who knows he has recent and active syphilitic disease, should be taken cognisance of by the law, and regarded as a crime not much less grave than manslaughter; and the same is true of such proceedings as that of a lying-in woman who, knowing she has syphilitic sores on her pudendum, fails to warn her accoucheur of the circumstance. Disease and death coming in this deliberately careless way, surely involve not less horrible and heinous criminality than any other offence.

The education of women for the important profession of midwifery has long been carried on, in many quarters in these countries, with more or less completeness, and with very good results. It has been, and is, the custom to give to pupils a course of lectures, and to require practical instruction and some experience, before conferring a diploma or certificate of competency to manage ordinary natural labour and puerperal state. Nearly ten years ago this Society prescribed a modest curriculum for pupil-midwives, and established an examination to test their attainments, with a view to granting a diploma to such as gave satisfaction to the Society's examining board. This good scheme has had an encouraging amount of success, the numbers passing in each year, from 1872 to 1880 inclusive, being 6, 11, 4, 2, 3, 4, 5, 12, 22. But this does not satisfy us. We want a recognised legal position, chiefly registration, for graduates, and we desire a great increase of members taught and seeking our diploma.

In some foreign countries, to which we look as examples for consideration rather than imitation, the education, registration, and regulation of midwives have long been carried on with apparent satisfaction to all parties. You all know the text-books for midwives issued under Government auspices in Germany. I have brought with me the book of the rules of midwifery service in the kingdom of Wurtemberg, issued by authority of the Ministry of the Interior. I also show you the remarkably cheap, handy, and useful obstetric bag which is recommended to midwives in that kingdom. Foreign obstetric conditions are, as I have already said, very different from those of the United Kingdom; and, of course, the Government arrangements are not exactly what we should desire for our country, with its limited employment of midwives, and what we consider the freer spirit of our laws.

Our examination system has recently been extended by the Society empowering its honorary local secretaries to conduct the written examination. This diminishes the expenses of candidates by reducing greatly the number of days spent in London, a single day for *vivâ voce* examination being now sufficient. That this widening of the area of easy working of our midwifery system is a good proceeding I have no doubt; indeed, the improvement and extension of the practice of ordinary midwifery by women is a most desirable object. Many people still living remember the time when the whole of this practice was in female hands. It was taken from them, not by the other sex because they were male, but in consequence of their superior education and scientific attainments. Science overthrew all the prejudice against man-midwifery, and this was not a small matter; for authority as well as prejudice were at one time so strong on the side of women as to bring Dr. Wertt to be burned at the stake for attending a woman in labour. If women are to be reinstated in the practice of midwifery, whether in unnatural or in natural labour, it is education and science alone that can do it, and women may be sure that these are irresistible. Meantime we are interested only in the extension of women's usefulness in ordinary cases, natural or nearly natural, and our object is to secure for the public a class of such women, reliable because duly qualified. The gain to the greatest number will be considerable, for the service of midwives is, of course, got at a less rate than that of fully educated practitioners, whether male or female. Besides, such fully educated practitioners are gainers, for their time and health are so valuable, and rapidly increasing in value, as to make it a very hard struggle to do full justice to their cases. Everyone knows how necessary patience and long waiting are for the performance of midwifery duty, and no one is proof against the bias given by impulses of time and health. The more extensive employment of midwives will greatly improve the care of the poorest and largest class. Such women are comparatively easily remunerated; they go to their cases unembarrassed by other important and pressing engagements, and they expect, without regard to the nature of the case, to have a stay greatly longer than is anticipated by the fully qualified practitioner. Against advantages there are, no doubt, disadvantages; and here, as in innumerable other difficulties, we make the best attainable compromise.

We have naturally been disappointed at the political delay of our scheme for the education and registration of midwives; but we are not discouraged, because we have no active opposition, and the urgency of the matter is daily increasing. Indeed, if we consider the gradual growth and progress of all such schemes in this country, and the still only partially developed state of our own midwives' arrangements, we may even assume that the delay does not involve loss of time, but will add, when the proper opportunity comes, irresistible force to our appeal to the Government.

We shall, no doubt, carry with us the sympathy—we hope also the active support—of the Medical Council. This medical Parliament, embodying as it does the political knowledge and experience of the profession, will surely do its duty by us, for it has hitherto shown itself wisely zealous for the interests of the public, not hesitating, after due consideration, to go beyond its chartered duties when such interests pointed the course.

The presence in the Council of an obstetric member has never been indispensable, yet always desirable; and the deficiency of such a member has been keenly felt, and, of course, most by us whose interests are especially dear to ourselves. When the education and registration of midwives come within the range of practical politics, we trust an obstetric member or obstetric members will be in the Council to give aid. On the death of Dr. Hudson your Council seized the opportunity to memorialise the Government with a view to the filling of the vacant place by an obstetrician, and I am happy to tell you we have gained our end, for I have a letter from the Lord President of the Council assuring me that the wishes of the Society will be carried out.

You are all well aware of the preparations that are being diligently carried on for the meeting of the International Medical Congress in this metropolis in August, and no doubt take especial interest in that part of it called the Section of Obstetric Medicine and Surgery. The general and executive committees of the Congress have nominated for this Section a president, vice-presidents, council, and secretaries, embracing a large number of distinguished physicians whose names will certainly command the confidence and respect of our brethren both at home and abroad. When the Section meets, honorary presidents will be elected from among the eminent obstetricians who, we already know, will come to the Congress.

The importance and usefulness of such meetings as this call for no remarks, for their very existence is in itself almost a sufficient demonstration of them. We are living in an epoch of great development of scientific parliaments; and no one dares to predict, though he may rejoice to anticipate, to what good result this will lead. Scientific Societies have flourished in great towns ever since the revival of learning. National scientific meetings have been regularly established only within our own times, or are being established now. But this kind of progress may be said to proceed in a sort of geometrical ratio. Political conferences are of comparatively old date, and have only a remote analogy with the scientific congresses; but the great Industrial Exhibition of 1851 no doubt offers a striking resemblance to our Medical Congress, and it inaugurated an era of international activity laden with many peaceful blessings.

Our own Society was started only twenty years ago; it had no perceptible period of infancy or adolescence, but from the first bore the appearance and produced the fruits of a mature association. Its founders had, in their sound judgment, justly estimated what was wanted, for, accordingly, our Society has supplied the want, and has prospered. It was not enough to have occasional allotted portions of the meetings of the Royal Medico-Chirurgical Society and a few papers in its annual volume of Transactions. Obstetrics and gynæcology had commenced rapidly to grow, not only in bulk but also in philosophic elaboration. The metropolis required monthly meetings devoted entirely to the subject of our practice and study, and this activity is represented not by a few papers of observation in Medico-Chirurgical Transactions, but by an annual obstetrical volume, rich not in mere observation and dogmatism, but also in speculation, experiment, and research. Under the auspices of the British Medical Association we have a great annual national medical congress which, not many years ago, began to have a special obstetric section. But already all this is not enough. Professional brotherhood, the jostling of co-operating intellects, the comparison of results in practice, are increasingly exigent. Meetings in all great towns and national meetings do not supply the demand, and now for the first time a cosmopolitan Obstetric Congress will be held in the greatest city of the world. It is not enough to anticipate or wish for great results of this August meeting. We must contribute to its success according to our opportunity and ability; and everyone of us can contribute something, if only contagious enthusiasm or mere sympathetic bodily presence.

Accoucheurs and gynæcologists are generally styled, or style themselves, physicians; but they are as much surgeons as physicians, and indeed a great authority has recently asserted, *ex cathedrâ*, that they are more surgical than medical. I do not think so, and, curiously enough, the great authority, although President of the Irish College of Surgeons, is himself an illustrious example of the preponderance of the medical element. Truth to tell, our department is like medicine in general, divided into two friendly co-operating camps, the medical and the surgical, and each man is driven into either, or remains mongrel, according to his special genius. Most begin by affecting the simpler, and in many respects easier, line of surgery, but most end with the conviction that they have not the rare surgical genius. At present the strong currents in obstetrics and gynæcology are rushing in the surgical direction, and too strongly so in the opinion of many intelligent observers. But it is foolish to deprecate this progress, and vain to attempt to change it. The unknown laws of the growth of our department of science and practice are not to be bent according to our shortsightedness to suit our views. The present surgical wave is undoubtedly doing good, and we cannot avoid its sweep, although we might wish it were less strong or had its medical equivalent. Accordingly, in the international obstetric programme it will be found that, for this year at least, surgery is paramount, yet not drowning, far less excluding, medicine. There is, indeed, still plenty of sectional time and space for medicine to occupy and reassert its preponderance over surgery. The authorities of the Congress invite you, as well as foreigners, to come forward with such results of observation, experiment, and research as you may have to offer for the consideration of the cosmopolitan assemblage of brethren who will have come for this purpose from all parts of the world. Every student is aware of the considerable differences that exist among the nations in their mode of describing and discussing the same obstetric and gynæcological matters. This is well illustrated by textbooks. A German or French manual, even if undoubtedly far superior to an English one, cannot be made by clever translation to take its place. The foreign work does not fit into our literary system, and it proves valuable chiefly by being mentally assimilated by British readers, and thus made part and parcel of our historical British literary development. If the differences among British obstetricians are enough to give a varied interest and instructiveness to our meetings here, how much more of striking and useful variation may we look for in an International Congress? We may expect to get not only original and new instruction, but to be edified by having old things shown us in a new light.

To conclude, gentlemen. While in medical politics this Society is working for the good of others, each member has to consider how he can make the Society itself greater, and himself more useful through it, and his spirit should be that of the happy warrior,

> "Who, if he rise to station of command,
> Rises by open means; and there will stand
> On honourable terms or else retire;
> Who comprehends his trust, and to the same
> Keeps faithful with a singleness of aim;
> And therefore does not stoop, nor lie in wait
> For wealth or honour, or for worldly state;
> Whom they must follow; on whose head must fall,
> Like showers of manna, if they come at all."

HAMMAM R'IRHA, ALGERIA: A WINTER HEALTH-RESORT.

By G. D. POLLOCK, F.R.C.S. ENG.,
SURGEON IN ORDINARY TO H.R.H. THE PRINCE OF WALES, CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

IT may interest many of the readers of THE LANCET to learn something of a warm health-resort in winter, within five days' easy journey of London, which at present is but little known in England, and which affords many advantages to invalids who require or desire something milder and more genial than the climate of an English winter and spring. While passing some few weeks lately in Algiers, I took advantage of fine weather to pay a visit to Hammam R'Irha, celebrated for its hot springs, and their beneficial effects in rheumatism. "The thermal springs of Hammam R'Irha," writes Colonel Playfair,[1] H.B.M. Consul at Algiers, "occupy the site of the ancient Roman city of Aquæ Calidæ, the ruins of which cover the hill-side for a considerable distance." The hotel and bathing establishment at Hammam R'Irha stand some 2000 feet above the sea level, near the summit of a broad face of mountain, looking south. The hot spring rises behind, and several feet above the hotel, on sloping ground running back some distance on the north side of the building. The outflow is constant and abundant. The water is conducted directly to the hotel, through which it flows continuously night and day. The point at which the water issues from its source is some five minutes' walk from the hotel, and may be readily reached by an ascent among the ruins of the old Roman town. The spring is covered in, but is left open in front to permit the escape of steam, and for the convenience of taking water from the fountain-head. The visitor may here satisfy his curiosity as to its temperature by dipping in his fingers. A few seconds will convince him that the experiment is sufficient. The temperature is stated to be about 115° Fahr., but as my thermometer was broken I could not verify the exact point. The heat, however, is sufficient to render the water too hot for a bath without a certain reduction of temperature. The supply is sufficient to afford a continuous stream for two swimming-baths, for the use of men and women resident at the hotel, also for private baths, and three large baths for the use of the Arabs. Night or day a hot bath is available at a few minutes' notice, and the rush of water may be continuously heard—not an unpleasant sound in the still night—as it pours from the pipes which discharge their contents into the large swimming-bath chambers. In 1841 the French military authorities established a hospital here for the use of soldiers; and in 1878 a very comfortable hotel, with bathing establishment, was opened for the use of civilians. Mons. Arles-Dufour, the proprietor of this establishment, is under an engagement with the Algerian Government to convert the present hotel into a hospital for civilians, to contain sixty beds, thirty for each sex. This arrangement will be carried out as soon as a new hotel, now in process of building on the higher ground, is ready for the reception of visitors. This hospital is to be devoted to the treatment alone of such cases as are likely to be benefited by the use of the hot baths.

---

[1] Handbook for Travellers in Algeria and Tunis, second edition, p. 171. London: John Murray.

The waters of Hammam R'Irha are, however, of two kinds. 1. The hot spring already mentioned, containing small quantities of sulphates and carbonates of lime and magnesia, &c. 2. A cold and slightly gaseous water used for drinking, containing small proportions of iron, soda, magnesia, &c. Mr. Squire has kindly offered to furnish me with an analysis of both waters, and when completed the results shall be forwarded to THE LANCET.

The Arabs have great faith in the beneficial effects of the hot spring, and have recourse to the baths in various disorders. With them, however, it appears also to be somewhat of a religious ceremony to pay a visit once a year to Hammam R'Irha, and "to wash and be clean." They have the belief that here is the tomb of some "Marabout," a holy man of ancient times, and that the said Marabout still supplies daily 2000 camels to convey the wood necessary to feed the subterranean fires which heat this water, for the physical, as well as spiritual, benefit of the faithful. There are distinct and separate baths for visitors at the hotel; for the Jews an establishment apart from the hotel; and for the Arabs in a building in front and below the hotel. Visitors need fear no annoyance or inconvenience from the latter, though they flock there in numbers. The situation of the present hotel is all one could desire as regards sanitary conditions; the new hotel will stand still higher. Below is the valley of Oued-Djer; through this valley runs a tortuous river. In rainy weather it is a great torrent; at the time of my visit it was but a slight stream. Beyond the valley, on the opposite side of the river, is a range of mountain well clothed with wood. Mountains also on either side—with the remarkable Zakkar—affording to the artist a fine subject for his brush. It is altogether a beautiful outlook, and in spring-time the ground is a carpet of flowers. The ascent to the hotel from the road in the valley is a zigzag right and left; for by no other mode of approach would this height be accessible in a carriage drawn by horses. The hotel affords every comfort to the traveller, or the invalid, that can be desired; and here the sick man finds a climate, and advantages in light and air, which no place in England can ever give in winter, or, indeed, I might add, can be found in any part of Europe. The situation among the mountains, the dryness of the atmosphere and soil, the bright blue sky and glorious warm sun (tropical showers and occasional wet days excepted), the abundance of hot water for bathing—all these combined afford to a certain class of invalids, or delicate persons, a most charming combination: enjoyment waiting on convalescence, to be followed by that consummation, so devoutly to be wished, and sought, and secured —Health!

I would particularly recommend Hammam R'Irha for a winter residence to those who suffer from those chronic forms of rheumatism which defy the attacks of medicine and puzzle the cunning of the experienced prescriber. There is a secret in the atmosphere, or soil, or elevation, or in the action of the baths, or all combined, which, in such a situation, brings health and strength in a comparatively short time, where otherwise months might elapse before an equal amount of benefit would be attained elsewhere. I also think it would be equally beneficial in cases of chronic bronchitis, and especially to those who suffer from damp and cold. Here the invalid is sure of sunshine and warmth, and quite exempt from the frost and cold winds, which are too frequently met with on the south coast of France. Hammam R'Irha offers a change and a charm which many may like to avail themselves of; and as a change, or even temporary residence, in winter, I know of no place offering similar advantages within the same distance and as accessible from London. Visitors should provide themselves with such dress as they would wear in England—light as well as warm clothing. As the sun goes down a great coat is more than a pleasant companion; it is a necessity to the invalid. In the winter evenings a fire is often agreeable, as also in rainy weather, but there are few days in which some amount of out-door exercise cannot be obtained. Light clothing is the rule by day, warm clothing the exception.

Egypt offers many advantages in climate and interesting associations to the invalid traveller in winter; but I doubt whether, as a winter residence and sanatorium, it offers such as are obtainable at Hammam R'Irha. Travelling in Egypt is very costly, and the invalid has to travel a much greater distance to gain the object in view. Hammam R'Irha may be reached through France in five days with comparatively easy travelling. The passenger who leaves London on Thursday morning may see Algiers harbour-lights by Sunday night, and on Monday morning take the train for Bou-Medfa station, where a carriage can be procured, which will deposit him at the hotel at Hammam R'Irha in time for dinner. But a few days may be agreeably passed in Algiers, and advantage of this delay can be taken to secure accommodation at the hotel, as well as the carriage at the station, for those who prefer to travel by rail. Hammam R'Irha is about sixty miles from Algiers. Those who can afford the time, and wish to see something more of the country than a railway train permits, may drive the distance, as I did, in two days.

The idle rambler would probably find himself satisfied with a few days' residence at Hammam R'Irha, but for the invalid, who would shun cold and damp for sun and warmth in winter, this may be made a most enjoyable residence for many weeks. Books can be procured from Algiers; letters and newspapers are daily delivered at 11 A.M.; the post leaves at five, and a telegraph office is attached to the hotel. The walks and rides, though not offering much variety, are sufficient in extent and picturesqueness to satisfy all who find their reward in renovation of health. For those unable to walk much there are verandahs to sit in, and gardens to stroll about, which enable the weaker ones to enjoy the open air without fatigue. A forest of some 1800 acres near the hotel affords a pleasant walk, and no fear of molestation from Arabs or live lions need be entertained. The former are well conducted, and not obtrusive; the latter are now "an unknown quantity" in this part of Africa. The water from the cold spring is pleasant to drink, and an agreeable addition to the vin ordinaire of the table-d'hôte. It is supplied in all the bedrooms, and at meals, without extra charge. With some persons it acts slightly as an aperient, and, as it contains a small percentage of iron, is said to be useful in cases of chlorosis, &c.

Hammam R'Irha affords much that is of interest to the antiquarian. The excavations for the foundations of the new hotel have exposed the walls and basements of many an old Roman house. Stone coffins, corn-mill, and numerous coins have also been found, and are to be placed in a museum to be attached to the future hotel.

The charges at the present hotel are very moderate, nine francs a day for board and lodging. The table-d'hôte is excellent, the bedrooms clean and comfortable, and a spacious glazed-in verandah looking south, with a cheerful drawing-room, make up the internal accommodation.

The railway from Algiers to Oran affords the visitor at Hamman R'Irha a ready mode of seeing much of the country, should inclination direct and health and pocket permit. If he requires further information on this point he cannot do better than consult an interesting book lately published, "The New Playground, or Wanderings in Algeria."[2] As to cost, the journey *viâ* Paris and Marseilles from London to Hammam R'Irha may be put down at £20 for each person travelling first class. Something more must be added if the traveller rests on his journey. Those who do not object to the sea may go direct to Algiers from London by steamer. The British India boats occupy about ten days in the passage, and on this route a visit to Lisbon is not to be lost sight of, and "is thrown in gratis."

---

[2] By Alex. A. Knox. London: C. Kegan Paul and Co.

Individually I owe much to the climate of Africa. A severe sufferer from rheumatism in August last I was induced, with kind friends, to pass two months on the south coast of the Mediterranean, and as a result returned in full health and strength to encounter the effects of an almost arctic winter "without let or hindrance." I feel I cannot do a greater service than point to the great advantages of such a climate in winter, in convalescence, or in such conditions as have above been referred to. I would say to all who can afford the time and the cost, "go and do likewise."

Grosvenor-street, W.

TREATMENT OF PLEURISY AND EMPYEMA.

BY JOHN E. MORGAN, M.A., M.D. OXON.,
PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY, AND PROFESSOR OF MEDICINE IN THE VICTORIA UNIVERSITY.

(Concluded from p. 326.)

SUCH, then, is the mode of treatment I have found most efficacious in pleurisy with serous effusion. By means of the spirometer we decide whether or not absorption is going on; if not, paracentesis is performed, and a small quantity of fluid only removed, the patient at the same time being directed to inflate his lungs with compressed air. But we will assume that the disease is empyema, and the pleural sac filled with pus. What, then, must be our treatment? In the first place, how shall we decide whether or not the exudation really is purulent? This question it is impossible to answer with any degree of certainty, unless we make an exploratory puncture. If the temperature be high; if likewise the heat of the skin over the affected side is persistently a degree or more higher than that of the healthy side; if also the skin over the region of the effusion be œdematous,—we shall then have strong grounds for concluding that the exudation is purulent. Still, none of these signs is pathognomonic. An exploratory puncture may readily be made by means of a subcutaneous injection syringe. In this manner we may prove to ocular demonstration whether pus be present or not. If it be present, we shall be merely wasting our time in attempting to get rid of it either by means of the aspirator or syringe. We may withdraw it as often as we please, but it will certainly reaccumulate. So long as it does so, the pulmonary and costal pleuræ are liable to suffer from the corrosive properties of the purulent exudation; while the adhesions, which will inevitably bind down the lung, become week by week more firm and unyielding. Thus, delay in acting energetically is not alone harmless, it is absolutely mischievous. No time should be lost. But how are we to proceed?

In the first place an incision should be made in the fifth or sixth intercostal space, midway between the two ribs, about an inch and a half in length. Into this incision a cannula should be inserted, with a view of keeping the wound open, the cannula being covered with tow steeped in carbolic acid. The aperture ought to be made as near the mammary line as possible. The patient should be directed to lie on his side for about forty-eight hours, in such a position as shall favour the escape of pus from the thorax. At the end of that time the cannula must be withdrawn, and a silver catheter inserted into the wound. A four-ounce exhausting syringe should be attached to the catheter, and with it the remaining portion of the purulent exudation should be thoroughly removed. Unless a syringe or aspirator be used, comparatively little fluid will escape. It will not, in fact, flow out unless the pressure within the pleural sac exceeds the atmospheric pressure without.

For this reason we often find that when the chest is opened, fluid only wells out during expiration. During inspiration not only does the pus cease to flow, but air is liable to be sucked through the orifice. After removing the purulent contents of the thorax, the most effective way of dealing with the suppurating surface of the pleura consists in conveying spray from a Lister spray-producer directly into the chest along a catheter. In this manner the spray diffuses itself through the interior of the thoracic cavity, and seems to act less injuriously on the delicate granulations of the pleura than when fluid in considerable quantities is introduced either by the irrigator or the syringe. Before, however, the spray is directed into the sac, all pus must be entirely removed, and as each syringeful of pus is withdrawn, a solution of carbolic acid must be injected in its place, till all trace of purulent contamination has entirely disappeared. In protracted cases it is very necessary to change the disinfecting lotions as often as we find the one we are using ceases to act beneficially. If carbolic acid be employed for any length of time in large quantities, the urine is liable to assume a dark olive-green colour, which should warn us to discontinue its use. In place of it we may try iodine, in the proportion of half a drachm of the tincture to the ounce of water, or if there be much depression, quinine may be substituted. If the discharge be offensive, a solution of the permanganate of potash answers remarkably well. After the operation, the cannula is usually allowed to remain in the wound for two or three days; it is then removed, and the aperture kept open by means of a small plug of lint steeped in a solution of carbolic acid. The presence of the cannula often occasions considerable pain and discomfort. If there is any tendency in the wound to close to such an extent as not to admit a catheter, it is dilated by means of a sponge pessary.

During the whole treatment the temperature must be closely watched. It should be taken twice daily, and in some cases three or four times. If the lungs generally are healthy, and there is no tuberculous disease, a rise of two or three degrees in the thermometer will almost certainly indicate that pus is collecting in some portion of the pleural sac, and is poisoning the system. If the pus be fetid, four or five degrees Fahrenheit will probably be indicated. Here the plan of treatment by means of silver catheters will be found peculiarly valuable, and we shall likewise discover the advantage of having mastered the physical geography of the pleural sac; for if we are to bring down the temperature we must break down adhesions and liberate the imprisoned receptacles of pus. Traube, who has written very ably on this subject, maintains that whenever it is necessary to have recourse to the radical operation, Nélaton's catheters should be used, because they are softer than any others. In my opinion, it is their softness which renders them unsuitable for the work we now require of them. We cannot by their means release the encapsulated reservoirs of pus. In the literature of this subject we find frequent reference to failures arising from this cause. Thus, Frantzel (in speaking of five cases in which the radical operation was performed by Moutard-Martin, which terminated fatally) observed "in these five cases, the pleural cavity was subdivided into several sacs by false membranes, and these could not be sufficiently cleared out by the rinsings; in consequence of this the pleural sac ichorised." The experience I have had has convinced me that sufficient care is not taken to get rid of the pus thoroughly and completely. I have frequently seen patients treated after the orthodox fashion (a perforated tube being passed through the thorax along which the pus was expected to find a free outlet), apparently make a good recovery. The discharge gradually ceased, the wound closed, and the patient left the hospital nominally well. The cure, however, was not permanent; caseous degenerative changes occurred in the retained pus, tubercular disease was set up, and death supervened after a protracted illness. To prevent such accidents free egress must be found for the pus. In several cases in which the temperature rose rapidly and unexpectedly during treatment, the feverish symptoms were attributed to the presence of pus, which it was impossible to liberate from within. Here a second or even a third opening was made in the thoracic wall, through which the peccant fluid was readily withdrawn. The situation for this outlet being determined by the thermometer. For where there are underlying purulent deposits there the temperature of the superimposed skin will be higher than over the remaining portions of the surface of the chest.

In treating empyema we must never forget that certain products of inflammation are destructive, and incapable of being organised. So long as they remain in the system they will inevitably prove a source of irritation. It should be our constant endeavour to assist in removing these destructive products of inflammation. The bands of fibrin we should also, as far as practicable, break down as they are forming. They contribute largely to that unsightly retraction of the chest which is so frequent an attendant on protracted cases of empyema. It has been proved to demonstration that the fibrin takes no very active share in the organising process. It cripples the expansion of the lung and binds it down to the ribs. Rindfleisch, in describing the inflammation of serous membranes in cases of pleurisy, observes:—"We must divide the layer of exudation which lies loosely on the serous surface into two strata—an upper one, which consists of fibrin, and a deeper stratum of young connective tissue formed by a proliferation of the connective tissue of the serous membrane. Upon the surface of the serous membrane connective tissue corpuscles appear embedded in a clear matrix, containing mucin, together with which they make up the layer of embryonic tissue. From these cells and matrix the true 'plastic exudation' is really formed, and not, as used erroneously to be supposed, by the fibrin."

I propose, in the next place, to refer to two typical cases, which appear to me to illustrate the preceding remarks. In these cases the difficulties I have discussed were strikingly exemplified, still the results of treatment proved eminently satisfactory. The first is that of a youth named Charles M——, aged nineteen, who was admitted into the Manchester Infirmary under my care on the 19th of February, 1877. At that time he was suffering from multilocular empyema. On two previous occasions he had been an inmate of the infirmary, and three times considerable quantities of purulent fluid had been removed from the right side of the thorax. Soon after his admission he was again tapped, two pints and eight ounces of pus being withdrawn. The chest, however, rapidly refilled, and the condition of the patient became very critical. Though 5 ft. 4 in. in height, his vital capacity was only 70 cubic inches, instead of being about 200 inches, the normal standard for persons of his height. The evening temperature averaged 103°. The pulse ranged from 110 to 120, and the respiration from 40 to 50 in the minute. The urine likewise contained considerable quantities of albumen, and there were signs of amyloid disease about the kidneys and liver. The digestive organs also were in an irritable state. Frequent attacks of sickness and uncontrollable diarrhœa rendered him day by day more prostrate and reduced. I determined, therefore, to have recourse to the radical operation without further delay. In the early part of April an incision was made between the fourth and fifth ribs on the right side in the mammary line. Into this aperture a cannula was inserted, and the pus permitted, as far as possible, to empty itself from the thoracic cavity. The quantity that escaped, however, was comparatively small; and on exploring the interior of the pleural sac with a long bent probe, I discovered that its cavity was intersected by tough fibrous ribbons, which subdivided it into pouches, within which considerable quantities of pus were encapsulated. As the adhesions were of long standing and very tough, it was found impossible to liberate the imprisoned contents of these receptacles with the catheter or probe. It appeared to me, therefore, that the only way of meeting the difficulty was to carry a trocar and cannula completely through the chest. This was done under chloroform by my friend and colleague, Professor Lund. A long trocar and cannula, specially constructed for the operation, were inserted into the chest, through the incision previously made. Whenever resistance was offered to the advance of the cannula, it was overcome by the protrusion of the trocar. In this manner numerous pent-up reservoirs of fetid pus were laid freely open, the instrument at times being diverted from its direct course and forced through the obstructing mass of adhesions which impeded its progress. As the different receptacles were entered large quantities of pus welled out of the anterior aperture of the chest; and when finally the extremity of the instrument was felt at the posterior part of the thorax, the trocar was forced through the ninth intercostal space, about two inches from the corresponding vertebra. The cannula was then withdrawn through the anterior opening, and the trocar, with a piece of perforated gutta-percha tubing threaded through its upper extremity, was carried completely through the chest. The two ends of the tube were then tied together, and the pleural sac daily washed out with a carbolic acid lotion. In this case it was found necessary to make a double opening, with a view of finding free egress for the pus. Unless, however, the case be very chronic and the adhesions exceptionally firm, I prefer breaking down the bands of fibrin and liberating the pus by a single opening.

This was a most tedious and protracted case, and clearly demonstrated the importance of keeping the pleural sac thoroughly clean, and not allowing pus to accumulate or stagnate in any portion of the chest. Over and over again, whenever the temperature rose, the interior of the pleural sac was carefully explored until the particular spot was discovered in which the pus was collected. As soon as this was liberated by the catheter and the source of irritation drawn off, the temperature immediately fell. The case was instructive in other ways also, for whenever the temperature rose only two degrees the patient lost weight, and was unable to take cod-liver oil, from which, when the feverish symptoms were absent, he invariably derived much benefit; albumen also reappeared in the urine, while the diarrhœa and sickness returned. For twelve months the chest was washed out every day. During this time the amount of fluid which the pleural sac was capable of containing was at stated times carefully measured. Immediately after the operation it held four pints and two ounces; but in the course of seven months it did not admit more than eight ounces. In the early part of the treatment the chest was washed out with carbolic acid and water. After a time, however, when the progress of the case seemed slow, tincture of iodine, in the proportion of half a drachm to the ounce of water, was substituted. On other occasions, again, chloride of sodium, quinine, and permanganate of potash were used. The temperature of the lotion employed ranged from 92° to 98°. While the dressing was proceeding a Lister spray-producer was directed upon the thorax, and after the rinsing out of the cavity was completed the spray was directed along a catheter into the pleural sac. During the treatment, likewise, the patient daily inhaled compressed air from Seigel's pneumatic apparatus. From the description I have given of this case it will be admitted that it was one of very great gravity. The remedial measures were perseveringly continued for eighteen months. The patient made an excellent recovery. This was one of three cases of empyema introduced by me to the notice of the Medical Society of Manchester in 1879. The patient then looked muscular and healthy. The difference between the two sides was comparatively insignificant. There was very little retraction. The chest was well developed and freely admitted air into regions which at one time had been rudely perforated by the trocar and cannula. The temperature was normal, the pulse regular and even, and the vital capacity had increased from 70 to 145 cubic inches. When I last saw this patient, some months ago, he informed me that he had completely regained health and strength, and felt sufficiently robust to undertake employment as a striker in an iron foundry, and was able to get through this laborious calling without experiencing any inconvenience or discomfort.

In another case, in which the patient was younger and the disease of shorter duration, the cure also was proportionately less protracted. An errand-boy, named James R——, aged thirteen, was admitted under my care into the Manchester Infirmary on Nov. 6th, 1878. The boy came direct from the fever hospital at Monsall, where he had been invalided with a slight attack of typhoid fever. When he was received at the infirmary the right side was found loaded with pus, and as he seemed well-nigh moribund a free incision was made in the anterior portion of the right side, between the fifth and sixth ribs, by Mr. Frederick Southam. A cannula was inserted into the wound, and the pus permitted to drain away for three days. The thoracic cavity was then explored in the manner I have described, and the chest washed out with a carbolic acid lotion every day, Lister's spray-producer being directed upon the aperture at the same time. In the notes of the case I observe that on several occasions the temperature, which had been nearly normal, suddenly rose to 102° and 103°. When such a rise occurred the cavity was probed with the catheter until a receptacle of pus was discovered and tapped, when the fever immediately ceased. The pulse at the same time became normal, and the appetite returned. In this case the incision into the chest was made on Nov. 6th, and on the 14th of the following February the wound had healed, and the cure was complete. During the whole time the patient daily inhaled compressed air. As the lung expanded he rapidly put on flesh; thus in the early part of November he weighed only 4 st. 6 lb., whereas on the 1st of the following March his weight was 5 st. 12 lb. The vital capacity also, as measured by the spirometer, increased in a corresponding ratio. On Nov. 16th, ten days after the operation, it did not exceed 50 cubic inches; on Jan. 8th he was able to expire 70 cubic inches; on Feb. 22nd, 79; on March 5th, 88; and three months later, 100 cubic inches. From inquiries I have lately made regarding this boy I find that he is now muscular and robust, and able to take part in such violent games as football and cricket.

In the two examples I have given it will be noted that the patients were young, one being nineteen, the other thirteen years of age, and it will readily be admitted that in the treatment of such a disease as empyema youth is a very potent and valuable ally. It may be said, indeed, that in early life the results of our curative measures will here be peculiarly satisfactory. No pains or care should then be spared, for even though the lung be reduced to an extreme degree of carnification, and though its tissue be hard and airless, and it has ceased to crepitate, still, if once the pressure be fairly taken off, and the lung be placed under favourable conditions for re-expansion, it will respond to our efforts, and once more become pervious to the air. We shall find also that even the non-vascular membranes which have invaded the pleura may, after a time, become vascular, and themselves assist in promoting absorption.

Still, though among the young we shall naturally achieve the greatest amount of success, yet even among older persons many seemingly desperate cases will reward us if we are prepared to bestow upon them the unceasing attention they require. This care must not be grudged. In protracted and anxious cases we shall need all the help we can obtain. That physician will be most successful who can count (as I acknowledge with gratitude was my case) on the loyal support of able assistants, energetic and intelligent clinical clerks, and skilled attentive nurses.

Manchester.

ON RESPIRATORY IRRIGATION: A NEW METHOD OF AFTER-TREATMENT IN EMPYEMA.

BY C. McIVHOR GOYDER, L.R.C.P., M.R.C.S. ENG.,
SENIOR HOUSE-SURGEON, NEWCASTLE-ON-TYNE INFIRMARY.

WHEN an empyema of the lung has been treated by incision with or without the resection of a portion of rib, and the case is treated antiseptically, healing by granulation and adhesion of the two layers of the pleura takes place oftentimes in a satisfactory way, and the case progresses to recovery in a manner leaving nothing to be desired. It as often, and perhaps more frequently, happens that when about two-thirds of the cavity have been obliterated the remaining third is slow to heal, the pleural surface continues daily to discharge a quantity of pus, the patient's health is undermined, and he becomes the subject of thoracic fistula, or the victim of tubercle or of waxy disease. It is hence an important matter to secure the total closure of the pleural interspace, and with such an object in view I venture to suggest the following treatment, which, through the kindness of Dr. Drummond, one of the physicians to this hospital, I have had the opportunity of trying. Some details of the case, so far as it has gone, will be subjoined.

The cavity of an empyema is an abscess cavity, and as such should be drained of its contents. Its walls also should be approximated in order to obtain if possible that secondary union by granulation which the surgeon attempts to obtain in limbs by pressure and careful bandaging. The contents of an empyema should be kept aseptic and the absorption of septic material prevented. Lastly, an empyema should be irrigated in order to wash away stagnant secretions. I am hopeful that these essentials of treatment will be gained by the process to be described.

Whilst dressing the patient referred to I was one day disappointed to find how much pus had accumulated in the pleural cavity on removal of the antiseptic dressings, and I determined to attempt to drain the cavity by placing the patient on the affected side with the wound lowest, at the same time inserting one end of a gutta-percha tube (eighteen inches long and a quarter of an inch in diameter) just within the cavity, and allowing the remainder of the tube to hang vertically downwards through a hole in the mattress, placing the opposite end in a jar of carbolic lotion. I should add that I attached the tube to the side by means of tapes carried round the body. My object was, of course, to prevent the entrance of air into the pleural cavity, and at the same time to drain the contents of the sac by gravitation.

After watching the arrangement for some time, I was surprised to find the level of the fluid in the jar sinking during inspiration, and again rising during expiration; and upon closely watching the continuity of the tube, I found it straighten itself somewhat at every inspiration. The fluid was, in fact, rising and falling during inspiration and expiration respectively. I next placed a piece of glass tubing in the continuity of the tube, near the chest-wall, and replaced the carbolic with Condy's fluid in the jar. I was at once gratified by seeing the pink Condy rushing up and down the pipe at every respiration. Now replacing the jar by a graduated measure, I found that something less than half an ounce of fluid was drawn up at every normal inspiration, and four ounces at every deep inspiration; the same quantities were ejected with corresponding expirations.

We have, then, a method of irrigation of the chest whereby the interior of an empyema is bathed at every respiration—a method which is constant, automatic, and to a certain extent under the control of the patient. The patient's position will ensure drainage by gravitation. The compression of the chest wall by means of a Martin's bandage (a method I have found useful in holding the tube in position), the patient's own weight as he lies on his affected side, and the hydrostatic pressure of a circular water-cushion around the tube, besides adding comfort to the patient, will all tend to produce that approximation of the two pleural surfaces and falling in of the chest wall which is so desirable. Lastly, the constant bathing of the interior of the sac with an antiseptic non-irritating fluid at the temperature of 100° F. ensures asepticity, and at once removes those products of inflammation at the site of their formation. The essentials of treatment before indicated are thus fulfilled.

Without entering into any details of the case in which I have used the above method of irrigation, suffice it to say that this plan was commenced on Dec. 7th, 1880, and has since been continued, with the exception of an occasional night, and is indeed still being used. During the five weeks that have elapsed the patient's temperature has ranged from 99° F. to 100° F., having only twice reached 101° F. He has gained four pounds in weight; he sleeps well, although the irrigation is continually going on. His appetite is good, tongue clean, and skin moist; he has no night sweats, and does not suffer any inconvenience from the process. Meantime the cavity is apparently getting less and the lung expanding. The jar of Condy's fluid is changed hourly. The tube is removed once in the twenty-four hours, and is then well cleansed in carbolic lotion. Upon removal of the tube no fluid of any kind escapes, although the air goes freely in and out of the chest.

The tube is made of stout black rubber such as is used for drainage-tubing, but it is not perforated laterally at all. Upon introducing it gently into the sinus a point is reached where resistance ceases, and where air is heard to rush through it. It is then fastened in by tapes which encircle the body; and when in position the upper opening of the tube should be *flush* with the inner surface of the parietal pleura. A Martin's bandage is then wound round the chest, and is adjusted above and below the tube. The patient is next placed on his affected side, with the tube through a hole in the bed, and between the patient's body and the mattress a ring water-cushion is placed. This renders the patient comfortable, and makes even pressure on his chest-wall. Hot Condy's fluid in the jar completes the arrangement; and the patient having made a full expiration, the free end of the tube is placed in the jar before the patient inspires. When he does so the pink fluid rushes up the tube, and thus air is prevented from gaining access to the chest.

Before concluding this paper, a few points occur to me which I trust may be of interest. The washings from the pleura were for some days set aside and deposited, and in those which were the first results of the process, shreds of lymph were very plentiful, also pus-cells, but at no time have blood-cells been seen. Regarding the mechanism of the process, the chest-walls, by their expansion, seem to create a partial vacuum, and this doubtless is greatly aided by the descent of the diaphragm. Hence the fluid enters during inspiration, and is emitted during expiration. That wall of the empyema formed by the expanding lung is apparently fixed, for were its expansion the cause of the entrance of fluids during respiration, these would be ejected during inspiration and drawn in during expiration; this is, however, not the case. It appears to me that the diaphragm is the great discomposing agent in these cases, and that were it possible to confine the movements of this muscle, one of the greatest difficulties in the attainment of mechanical rest would be removed.

In the very tranquil breathing of sleep, fluids arise only to the top of the pipe, and I think that however small the tendency, yet the weight of a column of water fourteen or sixteen inches high *does* tend to approximate the roof and floor of an empyematous sac, and that this is an agency for good.

I have noted above that the portion of tube in the chest was not perforated laterally, and I am sure that when these holes in tubes exist, the granulations quickly spring up and enter the perforations, seriously invading the calibre of the pipe. In fact, the granulations lining the sinus grasp the tube so firmly as to effectually prevent the entrance of air into the chest cavity *outside the tube*, and this in a case where a portion of rib has been resected.

As to the fluids with which to irrigate, I found carbolic acid solution (1 to 100) absorbed so quickly as to give rise to black urine in two days. Condy's is a very much pleasanter solution to work with, and the degree of interchange between it and the fluids of the sac is shown by the rapidity with which the solution becomes decolourised. From boracic acid solution I anticipate good results, and there are many other antiseptics of a similarly unirritating nature.

It may be objected that I have written more fully on this subject than the experience of one case can warrant, particularly as in that case irrigation is still *sub judice;* but I shall have accomplished my object if I have in any way pointed out a treatment which may be useful in a class of difficult cases. I should not like to conclude without stating how much I am indebted to Dr. Drummond for his kindness in the above case, nor without expressing a hope that the result may prove satisfactory to his patient.

Newcastle-on-Tyne.

ON FRAENTZEL'S ANTISEPTIC TREATMENT OF EMPYEMA.

BY G. B. FERGUSON, M.D. OXON.,
SURGEON TO THE CHELTENHAM HOSPITAL.

MR. MOXHAY having in THE LANCET of Jan. 15th narrated a case of empyema treated with noteworthy success after Fraentzel's method, as detailed in Ziemssen's Cyclopædia, I would wish to further place on record, to the credit of this method, two cases treated in the Cheltenham Hospital about eighteen months ago.

The first case was that of Annie M——, aged twenty-seven, who was admitted in July, 1879. About a year previously she had had pleurisy, followed by empyema, and had been treated in a great provincial hospital by aspiration, and afterwards by a drainage-tube. Nevertheless the fetid discharge continued, with temporary abatement only, and when first seen by myself she was exhausted and emaciated, was suffering from cough and hectic fever, was reported to be phthisical, and was not expected, at the utmost, to outlast a few weeks. Following Fraentzel's directions, a free incision, three inches long, was forthwith made anteriorly between the sixth and seventh ribs, and forty-five ounces of fetid pus were evacuated. A silver cannula was then inserted between the ribs, large enough to admit at once two No. 8 Jacques's india-rubber catheters. Through one was injected a stream of warm 1 per cent. carbolic lotion, which, with the residual pus, found its way out through the other, and this washing was continued till all was clean and sweet. The case being necessarily in some degree septic, the spray and formal dressings of Lister were omitted in favour of a simple gauze bag of carbolised tow, which was kept closely applied to the side. This washing process with carbolic lotion was continued twice daily for a fortnight; after which an iodine solution (tincture of iodine, two drachms and a half to one pint) was substituted for it and employed once daily. Speedily the discharge, which had already sunk to a drachm or so in a day, became quite insignificant, and the washing fluid from the first returned almost clear. After another month, there being still some trifling oozing, a 5 per cent. solution of common salt was used for washing purposes, and the silver cannula was replaced by a small india-rubber drainage-tube. After three months in all she left, having discarded the drainage-tube and with a nearly healed sinus. Three months after leaving I saw her again with the sinus firmly healed, her cough gone, increased nearly two stone in weight; in brief, perfectly well.

The second case, that of Clara A——, aged seven, admitted soon afterwards under the care of my colleague, Mr. Bennett, was equally satisfactory. Here the history was successively of scarlatina, dropsy, pleurisy, and empyema. The empyema, however, was not allowed to discharge itself, but Fraentzel's method with full Listerian precautions was adopted, and a pint of pus was removed. The twice and afterwards once daily washings were duly continued, and after a month I read in the hospital note book that the discharge had almost ceased. Five months afterwards the same book contains a mention of the firmly healed condition of the resulting sinus and of the perfect restoration of the patient.

I trust I may be right in my surmise that few, if any, institutions in this country have been more prompt than the Cheltenham Hospital to adopt this notable advance in the treatment of empyema.

Cheltenham.

TREATMENT OF EMPYEMA BY IRRIGATION AND ASPIRATION.

BY JOHN LOWE, L.R.C.S.I.

I WOULD like, with your kind permission, to make a few observations on Mr. Moxhay's article on the above subject in THE LANCET of Jan. 15th.

Mr. Moxhay claims priority in this country for treating empyema by aspiration and irrigation with Listerian precautions. I have seen this method practised several times, and I have practised it myself with success in a case of empyema proper. In those cases which I have seen, as well as in the case under my own care, Listerism was observed with most scrupulous precautions, not as in the case which Mr. Moxhay reports, where, I should say, Lister's method was either not fully comprehended, or, to say the least, was most imperfectly carried out. To open a deeply seated abscess in the thorax, and then to irrigate with simple distilled water, some time after with iodine, and subsequently with carbolic acid solution (two grains to the ounce), is manifestly contrary to Mr. Lister's practice. Mr. Lister would have used an antiseptic solution in the first instance, and this is the method I have seen practised so successfully by others, and until we are more enlightened than we are at present, I shall adhere to the practice which common sense dictates. It is a misrepresentation of our most philosophical surgeon's practice to hold that perfect Listerian precautions were observed in the case referred to; nor do I believe that when two grains of carbolic acid to an ounce of water were used there was even an element of probability that such a solution would have any effect upon disease germs.

We occasionally meet cases that recover as quickly without antiseptic precautions as they could with them, and may not Mr. Moxhay's case have been one of these? At any rate, it would, I think, have been better if Mr. Moxhay had described the case with which he had to deal. For instance, the state of the patient's health, whether the collection of purulent matter was circumscribed, how long it existed, and other points of interest which a scientific intelligence would suggest. A circumscribed empyemic abscess existing for a considerable time is hardly likely to cease discharging quickly; nor is it good practice to drain off the whole of the fluid at once in all cases.

Victoria-road, Battersea-park, S.W.

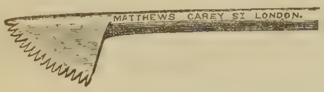
EDWARD GOODEVE MEMORIAL.—The execution of the bust of the late Dr. Goodeve, for the Medical College, Calcutta, has been entrusted to Mr. Geflowski, of Bruton-street. Mr. Geflowski's name is well known in India as a sculptor. The busts of Sir P. L. Cavagnari, Sir Cecil Beadon, Dr. Oldham, Mr. Arthur Grote, and many others, came from his studio.—*Home News.*

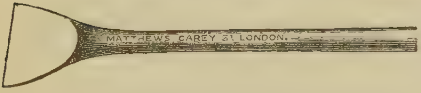
DESCRIPTION OF A SERRATED AND CUTTING CAUTERY IN THE OPERATION FOR HÆMORRHOIDS AND PROLAPSUS.

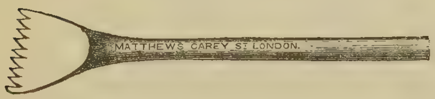
By HENRY SMITH, F.R.C.S.,
PROFESSOR OF SURGERY IN KING'S COLLEGE, SURGEON TO KING'S COLLEGE HOSPITAL.

I have until somewhat recently whilst performing the operation with the clamp and cautery for hæmorrhoids and prolapsus of the rectum employed the method as detailed in my article in "Holmes's System of Surgery," which consists in seizing and clamping the part to be removed, then excising the free portion by scissors, and subsequently cauterising the cut surface with the hot iron.

During the last year I have reverted to a method somewhat similar to that adopted originally by the late Mr. Cusack of Dublin, and instead of using the scissors for the purpose of removing the growths, I have employed cauteries so constructed that when heated they either cut through the tissues or saw them through at the same time that thorough cauterisation is effected. Mr. Matthews, at my desire, has furnished me with instruments having either a cutting edge or a serrated edge, as here delineated. The blades are set at right angles to the shaft or nearly parallel with it, according to the fancy of the operator. I employ both the cutting and the serrated cautery, according to the nature of the case. If the tumour or tumours to be removed are very large and vascular I use the latter, as the tissues are divided more slowly, and the cauterisation is more thorough; when the tumours are smaller and less vascular I use the cutting cautery.







I have now employed this method in a large number of cases both in hospital and private, and I strongly recommend it to those who practise this operation; time is saved, there is no need for the use of scissors, and, so far as my observation serves, there is a more thorough cauterisation effected—the cardinal point in this now safe and simple method of removing radically these serious and troublesome maladies.

I may mention also that these cauteries may be used with advantage in the removal of other growths besides hæmorrhoidal tumours; thus, for instance, I witnessed my colleague, Mr. Wood, use the heated cautery with the cutting edge in completing the separation of the broad pedicle of an ovarian cyst, which had been previously ligatured, but where a more thorough arrest of bleeding was required.

Wimpole street, W.

Testimonial.—A testimonial was presented on Feb. 23rd to Mr. Edward Charles Cripps, M.R.C.S., L.R.C.P. Lond., of Cirencester, by the officials and patients of the Highgate Infirmary, on his resigning the post of Assistant Resident Medical Officer, which he held for a period of two years. It consisted of a handsome clock and salver; the clock bearing the following inscription: "This clock, with a salver, was presented to Mr. Edward Charles Cripps, by the officers, nurses, servants, and patients of the Highgate Infirmary, as a token of their esteem on the occasion of his resigning the post of Assistant Medical Officer at that institution. Feb. 23rd, 1881."

THE CASE OF PROBABLE POISONING BY COLCHICUM.

By CHRISTIAN BUDD, M.B. Cantab.

In August last a gentleman, about fifty years of age, in good health, but subject to attacks of gout, went to Scotland for the shooting. Whilst there he had a slight attack of gout in his knee, which prevented him from walking, and at the end of ten days, in consequence of feeling unwell, he returned to Devonshire, where he arrived on a Saturday. On the following day (Sunday) he complained of nausea, with griping pains in the belly and diarrhœa. On the Monday he was seized with vomiting, and the diarrhœa continuing, a neighbouring medical man was called in. I imagine the usual remedies for arresting the diarrhœa and vomiting were had recourse to, without, however, in any material way mitigating the symptoms. The vomiting and diarrhœa continued throughout the week, and nothing remained on the stomach. On Tuesday, in the following week, another medical man was called in, and from that date I have an accurate record of the symptoms. At that time the patient lay in a state of semi-stupor, but, when roused, answered all questions clearly. There was not then, nor at any time, headache or delirium. The diarrhœa had ceased from the preceding night, but the vomiting was persistent, with frequent hiccough, and the belly was slightly tympanitic. The pulse was 80 to 82, and regular; the respiration natural; the temperature 96·5°. Upon examination the urine was found to contain some lithates, with a trace of albumen. To these symptoms were now added constant twitchings of the muscles, greatly aggravated by any movement. This state of things continued until Saturday night, when the vomiting ceased, but the patient's condition had become so alarming that, early on Sunday morning, I was called in consultation. On my arrival I found the patient in a state of semi-stupor, with his eyes shut, but when spoken to he answered questions clearly. His tongue and mouth were dry and brown, and he had frequent hiccough. The vomit of the preceding night contained dark-coloured flakes, as if stained with altered blood. The belly was tympanitic, and the bladder had ceased to act, so that he himself desired the catheter to be passed. This was done, and about a pint of apparently natural urine drawn off. The operation was repeated at regular intervals, as from that time he could pass no water without the aid of the instrument. The pulse remained at 80 to 82, and was regular, the respiration natural, and the temperature 96°. The twitchings of the muscles had increased, so that he had little control over their movements. As the bowels had not been moved for six days, a turpentine enema was administered, and was followed by two or three evacuations. On the following morning (Monday), in addition to the symptoms described above, he had paralysis of both arms; that of the left was complete, but he had still some little power in the right, and an effort to grasp one's hand brought on convulsive movements in it. On the Tuesday he was much in the same state; but on the Wednesday the pulse had become intermittent, the temperature had fallen to 95·5°, the twitchings were incessant, he had several involuntary motions, and at 10.45 P.M. he died comatose.

To what cause is this remarkable group of symptoms to be attributed? First, nausea, griping pains in the belly, diarrhœa, vomiting, and hiccough; then stupor, convulsive twitchings of the muscles, and, finally, paralysis and death. To my mind they resemble those of no ordinary malady, but are such as would be produced by an acrid narcotic poison; and it occurred to me whether, being gouty, the patient might not, accidentally or otherwise, have taken an overdose of colchicum. Upon inquiry I elicited from himself that he had been in the habit of taking "pills;" and that whilst in Scotland, to get rid of the gout in his knee, which interfered with his shooting, he had taken six pills daily until he he had finished two whole boxes of them. I have been unable to ascertain what sized box he took into Scotland with him; but it seems certain that, at the least, he took in four days and a half twenty-eight pills. I examined a fellow box of these pills and found them as hard as a stone, so that it is probable the pills remained for some length of time undissolved, and accumulated in the stomach and bowels until the dose may have become a poisonous one. I have since received from a medical man of eminence a report of a case of accidental poisoning by colchicum in which the symptoms were identical with those of my patient, and ended, in about the same length of time, in paralysis and death.

P.S.—Since the above was written I have received from my friend, Mr. A. Wynter Blyth, the Devon county analyst, an analysis of these pills, from which it appears that twenty-eight of them contain more colchicum than has in recorded cases caused death.

North Tawton, Devon.

NOTES OF A CASE IN WHICH THE PRINCIPAL SYMPTOM WAS A CONSTANT AND COPIOUS DISCHARGE OF WATERY FLUID FROM THE NOSE.

BY W. R. SPEIRS, M.B. & C.M.

HAVING observed in the Clinical Society's Transactions for 1879 a case reported by Sir James Paget, in which the principal symptom—a continuous dropping of watery fluid from the nostril—is there described by him as one of great rarity, the following note of a similar case which occurred in my practice may not be without interest.

In November, 1875, T. R——, aged fifty-five, a tailor, of medium height, spare and delicate-looking, consulted me as to a constant dropping of a clear watery fluid from his nose, which was at times so copious that any garment he was making became completely saturated in a very short time. This, he said, had been going on for nearly a month, and he was at length obliged to give up his work and seek advice. It commenced at first with sneezing, which he was inclined to attribute to the inhalation of dust arising from some coarse flannel upon which he was employed in making jackets for pitmen. Change of work, however, made no difference in the discharge, which went on as before. He could give no account of any injury received previously, and there was neither pain nor swelling at any time during the continuance of the flow. It came drop by drop, but at times almost so quickly as to form a stream; and on one occasion, when I wanted some of the fluid for examination, an egg-cup containing nearly an ounce was filled in a quarter of an hour. I have no note of the sp. gr. of the fluid, but it was perfectly clear and colourless, free from smell, and, according to the patient, had no taste. It contained no albumen, and a handkerchief thoroughly saturated with the discharge, on being held to the fire and dried, felt as soft and free from any stiffening as one that had not been used. No excoriation of the lip was produced, no matter how long the discharge was allowed to run over it. At night the patient was compelled to have his head raised till he was almost in a sitting posture, as when lying down the fluid ran back into his throat and caused a choking sensation. He noticed that the flow abated in some degree, but never quite ceased, when he took exercise in the open air, more especially if the atmosphere was clear and frosty, but immediately on coming in doors and entering a warm room it assumed its previous proportions. The sense of smell is now perfect, and was at no time during the flow in any way interfered with. In this case, as in Sir James Paget's, there was no appearance of disease in the mucous membrane of the nostril, and nothing whatever to indicate the source of the fluid. For nearly nine months the flow continued almost uniformly, certainly without any very decided variation in quantity, in spite of all the treatment adopted. This consisted of glycerine of tannin, tannic acid in powder, and various other astringents locally, whilst the general treatment aimed at acting on the lower bowel by purgatives in the way of counter-irritation. Liquid extract of ergot and liquor strychniæ were also persevered with for some time; but the case was finally cured (or, at any rate, the dropping ceased gradually day by day, until within a week it had quite disappeared) by keeping the nostrils always filled with goose-grease. Whether in this case the fluid came from the antrum, as post-mortem examination proved it to do in the case recorded by Sir James Paget, of course I cannot say, but presuming that the cases were identical, is it possible that the goose-grease which the patient himself applied experimentally filled up the fissure of communication between the antrum and middle meatus of the nose, and thereby so altered the existing condition of the structure lining that cavity as to effect a cessation of the excessive secretion? This appears to me to be a reasonable explanation of the result, and quite as satisfactory therapeutically as the treatment adopted by Sir Benjamin Brodie, whose case is referred to in Sir James Paget's report, which consisted of injection of solution of sulphate of zinc (three grains to an ounce) into the nostril, while the salt was at the same time administered internally. In the case referred to there were two separate attacks, and, considering that the second lasted twenty-three months presumably under the above treatment, it cannot be considered very satisfactory. Looking at the case anatomically, injection of solution of sulphate of zinc, or any other fluid, into the nostril, could not exert much, if any, influence over the lining membrane of the antrum.

The following therapeutic note in connexion with my patient may be worthy of record:—For twenty-seven years he suffered martyrdom from piles. He underwent an operation at the hands of a London hospital surgeon without benefit, but has been at length completely relieved from all pain and discomfort attending that condition by steadily persevering with glycerine in drachm doses twice daily, which I prescribed for him about three months ago, after seeing it recommended for that purpose by Dr. Young, of Florence, in the *Practitioner* for January, 1878.

LONDON HOSPITAL.

HYSTERO-EPILEPSY; PHASES LIKE THOSE DESCRIBED BY CHARCOT; OBSTRUCTIVE DYSMENORRHŒA; TREATMENT BY DILATATION OF CERVIX UTERI.

(Under the care of Dr. SANSOM.)

FOR the following notes we are indebted to Mr. G. T. Stonham, house-physician.

The patient, a fairly intelligent girl, a Roman Catholic, aged twenty-one, was admitted on Aug. 20th, 1880. She lived from the age of thirteen to seventeen in Canada. Her mother's father died of consumption, but there was no neurotic family history. As a child she had good health, but whilst in Canada, and even after, she had suffered much from headaches, and from frequent attacks of vomiting. She first menstruated at the age of eleven; had always been very irregular; her menses were scanty, lasting never more than three days, and always accompanied by severe pain, both constant and paroxysmal, referred vaguely to the back and to the front of the abdomen, and coming on at the commencement of the flow, and lasting till it ceased.

She was first taken with fits in April, 1880, in which she lay for about five minutes in a rigid condition, and with her eyes shut. She at the same time had great impairment of memory. These fits came on about once a day on an average till the middle of July, when they became much more frequent, and of a more violent character.

She had five fits on the first day of admission, lasting from a quarter of an hour to an hour, and several similar fits on many days following. A fit could at any time be excited by pressure on the ovaries, and during its manifestation pressure on the ovaries would either arrest it or alter its character. Pressure on other parts of the body did not produce a fit. They were most frequent about the time of a menstrual period, and she also seemed to be more liable to them after being visited by the priest. Between the fits she seemed cheerful and intelligent, but suffered a good deal at times from headache, which, she said, felt as "though nails were being hammered into her head."

The fit consisted of a series of stages:—1. They began by her head being thrown up, and inclined slightly to the right, while her eyes were turned up and to the right, and her mouth widely open. Her limbs were placed in a position approaching that of crucifixion, her legs extended and lying together, while her arms were held out straight nearly at right angles to the trunk, her fingers being over-extended, bent back towards the dorsum of the hand. 2. After lying quite still in this position for a short time she began to make lateral and to-and-fro movements with the tongue, and to froth at the mouth (she never bit her tongue). Her head began to move slightly from side to side, then more violently, till at last her whole body was implicated in a violent side-to-side movement. 3. These movements were soon exchanged for violent and extreme extension and flexion of the trunk: at one moment she bent forwards so that her head almost touched her feet; the next, threw her head violently back on to the bed. 4. She then again assumed the crucifixion position, and on some occasions arched her back in a rigid opisthotonos. 5. Finally, she drew several long breaths, her limbs relaxed, and she turned on to her left side, placed her hand over her heart, and began to cry; she then sat up, smiled, and said she felt tired and weak. During the fit the corneæ were insensitive, and pricking her with a pin caused her no pain in any part of the body.

Treatment was directed to the relief of the dysmenorrhœa, which Dr. Herman considered to be due to a narrow cervix. On Sept. 27th bougies Nos. 4 and 5 were passed; their passage excited a fit. On Oct. 5th bougies Nos. 6, 7, and 8 were passed; a fit again occurred. On Oct. 18th bougies Nos. 8, 9, and 10 were passed; a fit occurred afterwards. She at the same time took one grain of valerianate of zinc three times a day. Her fits soon began to diminish in frequency, till by the middle of October she did not have more than two a week. Her menstruation also became easier, and the pain was much lessened. Pressure on the ovaries produced much less effect. She menstruated on Nov. 30th and Dec. 1st without pain for the first time in her life. She had no fits after that, and when she left the hospital on Dec. 7th she had not had a fit for more than a month.

WEST LONDON HOSPITAL.

INJURY TO THE HEAD; PARALYSIS OF THE SAME SIDE; DEATH; SARCOMA IN CEREBRUM; REMARKS.

(Under the care of Mr. Cooper.)

For the following notes we are indebted to Mr. Sidney H. Lindeman, house-surgeon.

Thomas J——, aged forty-seven, was admitted on October 1st, 1880, suffering from the effects of a kick from a horse, on the left side of the face. He was sallow and thin, but not emaciated. He was quite unconscious, breathing deeply, but freely. Pupils equal. The left side of the face was smashed in. There were two lacerated wounds of the left cheek about one inch and a half in length, one above the other, running almost horizontally across the face. Through the upper one the malar bone could be felt fractured, the lower wound exposing the superior maxillary bone. Both eyes were ecchymosed, the left most extensively. After being in bed a short time, the right side of the body was convulsed, the left remaining quite motionless.

Oct. 2nd.—Still unconscious. There had been no movement of the left side, but the convulsions of the right side were so violent that, in order to keep the clothes on, the ankle and wrist had to be secured to the bed. Had groaned loudly, and with great difficulty was made to swallow some fluids. Left side of the face paralysed. Wounds looking healthy. 3rd.—Since admission his bowels had acted, and his bladder had emptied involuntarily. Consciousness returning. Right side movements not so strong. On the 4th he spoke indistinctly. Breathing loud and difficult. Sore forming over the sacrum. Had not moved the left side. Next day he answered questions. Complained of thirst. Tongue dry and furred. Mouth parched. Could swallow fluids only, and that with difficulty. He remained in the same state with left hemiplegia, left facial paralysis, the involuntary movements of the right side having almost ceased, till on the 10th, when for the first time he was delirious, crying out that he had pain in the back over the sacral sore. He only occasionally shut the left eye, generally sleeping with it open. Micturition and defecation involuntary. Tongue and mouth dry. Teeth covered with sordes. Could not swallow solids. Felt cold. On the 25th he complained of pain in the left arm. He could only just move the left thumb and first finger. There was a large collection of pus over the left heel, which was freely evacuated. Left ankle and knee swollen. On the 29th he had some slight control over the bladder, but none over the bowels.

On Nov. 1st, one month since admission, he had a vacant stare, the left eyeball being apparently more prominent than the right. Had complete hemiplegia, slept with eyelids only partially closed, but could close them both at will; had now some difficulty in moving the right arm and leg, especially the latter; movements of the left eye more sluggish than the right; can see normally with right, but with the left only objects held directly in front of it. Did not hear with the left ear so well as with the right, both being impaired. Answered questions intelligently, but mistook strangers for relations, and *vice versâ*. On the 5th the right side of the body was found to present the following condition. The leg was constantly being drawn up; the fingers were flexed on the palm of the hand, the hand on the wrist, and the forearm was drawn at a right angle with the arm. These positions were with difficulty overcome and immediately returned to the same state, when the limb was left alone. The patient had no power to straighten them, and could barely move his right arm at all; but the grasp of his right hand was fairly strong. On the 8th had a severe attack of hæmorrhage from the sacral sore. On the 12th the whole body was much emaciated. Had managed to take a small quantity of bread-and-butter; conversed rationally, and requested to be allowed to go home and die. He was gradually losing all motion in the right arm and leg. He had only slight power over the bladder, none over the bowel.

The patient became extremely weak, and died on the 14th. The temperature throughout varied from 99° to 102·8° F., the highest being registered at the time he was delirious.

Necropsy.—On removing the skull-cap it was found to have attached to it the membranes over the posterior lobe of the right hemisphere, everywhere else it was healthy. The cause of this attachment was readily shown. In the posterior lobe of the right hemisphere there was found an extremely hard tumour, about the size and shape of a hen's egg. To this the membranes were firmly adherent, forming, with the surface of the tumour, a hard leathery mass. The brain substance in its neighbourhood was softened, and beneath the pia mater, within and around the upper end of the fissure of Rolando, which was a little way in front of it, there was a thin clot. There were adhesions, and lymph effused about the upper extremity of the left parietal convolutions. A microscopic examination of the tumour showed it to be a spindle-celled sarcoma. It was elicited from his friends that for the last four years he had been subject to attacks of pain in the head, and had been constantly under medical treatment. He had never been sufficiently ill to prevent his following his usual employment, nor did he show any symptoms of paralysis. His sight and hearing were perfect. When a child he had a severe fall, and struck his head over the right orbit. He went to work on the day of the fatal accident in apparently good health.

Remarks.—The peculiarity of this case lies in the difficulty of detecting the precise seat of the lesion which caused the symptoms. The blow having been on the left side of the head, it was natural to expect paralysis of the right side, if we omit fracture by *contre-coup*. This may be explained thus. In all probability the cranial tumour in the right hemisphere had been growing some time, producing the pains in the head from which he had constantly suffered. Now, a brain containing anything which destroys its natural resilience would be more likely to receive much graver injuries from such an accident than one which is perfectly healthy. The sudden shock, therefore, from the violent blow on the face caused an extreme degree of concussion of the brain substance, already softened, in the neighbourhood of the tumour, together with a good deal of hæmorrhage into the arachnoid and the brain itself, as was shown by the necropsy. This explains the left hemiplegia. The hæmorrhage was greatest in and around the upper end of the fissure of Rolando, which Dr. Ferrier in his "Localisation of Cerebral Disease" designates as the region in which injuries produce paralysis of the opposite side. And as he has also shown that serious injury to the occipital lobes can be inflicted without giving rise to any subjective symptoms, so we should not be surprised to find that this tumour had not manifested its existence by anything more definite than headache.

Injuries to the cerebral meninges produce symptoms of irritation of the same side, and in this case the injuries they sustained in the region of the tumour would account for the irregular movements of the right side, observed for some days after his admission. The subsequent paralysis and contractions of this side were probably due to the inflammation having extended to the left side of the longitudinal fissure. The fixation of the left eyeball, and the facial paralysis (which was not well marked), can easily be explained by the supposition that there was some local nerve lesion.

MANCHESTER ROYAL INFIRMARY.

CASE OF HEPATIC ABSCESS.

(Under the care of Dr. WILLIAM ROBERTS and Mr. HEATH.)

FOR the following notes we are indebted to Mr. C. H. Bloxsome, house-surgeon.

Mark H——, aged forty-four, a labourer, was admitted under Dr. William Roberts on Sept. 24th, 1880. The family history was good. When ten years of age the patient had small-pox, but, with that exception, he had always been healthy. Seven years before admission he went to America, where he worked as a labourer in the backwoods; was much exposed to cold and wet, and had a severe attack of diarrhœa, which lasted a fortnight. There was, however, no history of dysentery, although he had occasionally been subject to short attacks of purging, which ceased after a few hours. He had for several years been in the habit of drinking large quantities of whisky. There was no history of syphilis.

About five months before admission patient became aware of a dull aching pain in his right side, followed by a swelling over the region of the liver. He laid up for three weeks, when, being worse, he returned to England, and shortly afterwards became an in-patient at the infirmary.

On admission he had a dusky, sallow complexion, with a careworn expression. He was fairly well nourished, though rather anæmic. In the epigastrium was an immovable tumour, rather tense, though fluctuation could be distinctly made out. There was dulness in the nipple line, extending from the lower border of the fifth rib of the right side to two inches below the costal margin.

On Oct. 26th a puncture was made into the tumour about an inch below the eighth right costal cartilage, and three ounces of very sanious pus were withdrawn by the aspirator.

On Nov. 2nd thirteen ounces of a similar fluid were evacuated in the same manner, giving great relief; and on the 7th the aspirator was again used, six ounces of fluid being withdrawn.

On Nov. 9th he was admitted into the surgical wards under Mr. Heath. Under the carbolic spray an incision an inch in length was made a little to the left of the right nipple line, and below the costal border, and a large-sized drainage-tube was inserted. About eight ounces of thick sanious pus were evacuated, and antiseptic dressing was applied, being fixed by a many-tailed bandage. There was such a large quantity of discharge that the wound was dressed twice daily until the third day, after which it was dressed once daily until the 15th, when a small quantity of eucalyptus and vaseline ointment (1 to 8) spread upon boracic lint was applied, the spray being still used. The quantity of discharge steadily decreasing, the drainage-tube was shortened by degrees until Dec. 8th, when it was discontinued altogether.

On Dec. 15th the spray was given up, the dressing being still applied every alternate day; and on the 21st the wound had completely healed. The patient was discharged Dec. 24th.

The temperature, which had previously been most irregular, varying from 103° F. to 96° F., became rapidly normal after the abscess was opened, and remained so throughout, never rising above 99° F.

THE total sum realised by the Hospital Saturday and Sunday collections in Manchester this year is £5053 13*s.* 4*d.* A few contributions not yet returned will, it is hoped, raise the sum to at least the average of former years.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Annual Meeting.—President's Address.

THE annual general meeting of this Society was held at the Society's rooms, 53, Berners-street, on the 1st. inst., the President, J. E. Erichsen, Esq., F.R.S., in the chair. The ballot for officers and Council for the ensuing year was taken, Dr. Legg and Mr. Gant acting as scrutineers. The following Fellows were elected to fill the offices:—President: Dr. Andrew Whyte Barclay. Vice-Presidents: Drs. A. B. Garrod and Habershon, and Messrs. Spencer Wells and Holmes. Treasurers: Dr. C. B. Radcliffe and Mr. Cooper Forster. Secretaries: Dr. R. E. Thompson and Mr. Berkeley Hill. Librarians: Dr. Sieveking and Mr. Hulke. Other members of the Council: Drs. Andrew, Cholmeley, Hilton Fagge, Sydney Ringer, and Reginald Southey, and Messrs. Gant, Langton, Francis Mason, John Morgan, and Alfred Willett.

The balance-sheet, which had been duly audited and previously circulated, was taken as read. In consequence of some unusual outlay, the finances were not as satisfactory as usual, there being a deficit in the income as opposed to the expediture of £70 10*s.* 6*d.* The number of new Fellows during the past year was twenty-four, less than the year before, but considerably above the average.

Mr. Holmes, the hon. secretary, read the report of the Council, the adoption of which was moved by Dr. Cholmeley, seconded by Mr. Cowell, and carried *nem. con.*

The PRESIDENT then delivered an address. He said that the meetings of the Society, the excellence of its published Transactions and of its unequalled library, were evidences of its satisfactory position; and as proof of the high estimation in which it was held was the fact that office in it was regarded as the highest distinction the profession could confer. At the same time, he thought its sphere of action might be increased, and that it would be of great advantage if an institution which kept aloof from education and medico-ethical and political questions could be more widely utilised for the investigation of questions of practical moment and importance to the community. He suggested that the inquiry of such subjects might be more frequently undertaken by Committees of the Society. He spoke also of the relation of the Society to the kindred societies, and advocated the scheme which in 1869 was nearly carried into effect of amalgamating or affiliating those societies into one central body, a Royal Academy of Medicine. The financial condition of the Society was not altogether satisfactory; its income was not sufficiently elastic to bear the strain of any unusual expenditure. It would not be possible to reduce the ordinary expenditure without impairing the efficiency of the Library, and he suggested that an annual subscription from non-resident Fellows might reasonably be demanded, the present fee being somewhat inadequate and not in proportion to the privileges derived Of course, any such change would only have a prospective effect. Mr. Erichsen then proceeded to give a brief sketch of the lives and work of Fellows deceased during the past year. The list comprised the names of Dr. D. Whitaker Cohen, Mr. Thomas Bell, F.R.S., the first legally qualified surgeon who devoted himself specially to dentistry, and whose zoological writings as well as his edition of Gilbert White's "Selborne" were well known; Dr. John Deakin Heaton, of Leeds; Dr. W. Sharpey, F.R.S., whose career and character were admirably portrayed: his wide knowledge "blended with wisdom," his unrivalled powers of exposition, his liberal instinct, and his devotion to medical education and science were dwelt on by the speaker, who knew him well; Dr. O'Connor, Mr. Ed. Amphlett, Dr. J. Pearson Irvine, Dr. Ed. I. Sparks, Dr. Ed. Goodeve, Dr. Geo. Moore, and Sir B. C. Brodie, M.A., Bart., late Professor of Chemistry at Oxford, and an honorary Fellow of the Society. In conclusion, Mr. Erichsen said that he had now to retire from the chair and resign the office which the Society had honoured him two years ago. That honour was one of great distinction to be conferred on a member of our profession. Few honours are given to our profession from without, and we may be allowed to prize those bestowed by the profession itself. Such honours are some recompense in after life to those who in early life have followed the steep and rugged roads of a professional career, and have not pursued the smiling by-paths which, although they may lead men to fortune, do not lead to fame. To a surgeon there was no honour greater than to be on the roll with the sixteen illustrious surgeons who had preceded him in that chair. For that great honour and distinction he most cordially thanked the Fellows, for he felt most grateful for it.

On the motion of Mr. SPENCER WELLS, seconded by Mr. PICK, a cordial vote of thanks was awarded to Mr. Erichsen for his duties as President and for his address, coupled with the request to allow it to be printed in the Proceedings of the Society.

Mr. MACNAMARA proposed, and Dr. WHIPHAM seconded, a vote of thanks to the retiring Vice-President.—Dr. SILVER proposed, and Mr. B. HILL seconded, a vote of thanks to the retiring Secretary and other officers, which was acknowledged by Mr. Holmes, and the meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

Treatment of Hydrocele.—Removal of Tongue for Cancer.—Treatment of Psoriasis by Turpentine and by Chrysophanic Acid.

AT the meeting of this Society on Feb. 21st, F. J. Gant, Esq., President, in the chair,—

Mr. S. OSBORN read notes of two cases of Hydrocele cured by single Tapping, with the subsequent use of the Galvano-suspension Bandage. The first was a case of hydrocele of the tunica vaginalis, which had been present for seven or eight years; and the second was a case of double encysted hydrocele, present for six years. Both patients were affected with rupture on the same side as the hydrocele, showing a preternatural weakness of the parts in the vicinity. The ages were seventy and sixty-three respectively. After tapping and manipulation the galvanic suspensory bandage was applied. The galvanism was believed not only to cause contraction of the muscular fibres of the scrotum, but to impart a healthy action to the serous sac, aiding absorption. Mr. Osborn recommended a trial of this bandage in other diseases of the testicle, such as varicocele and neuralgia testis. — The PRESIDENT referred to the value of manipulation, which often sufficed to provoke the inflammation necessary for the cure of hydrocele. — Mr. MASON, although he had heard of hydrocele being cured by a single tapping, had only met with one such case in his own practice. — Mr. ROYES BELL had not been satisfied with the plan of a single tapping followed by strapping, which had been much recommended. — Mr. PEARCE GOULD asked if the method advocated by Mr. Osborn produced any injury to the skin.—Dr. GIBBON had seen many failures follow tapping combined with strapping; the best results were obtained by acupuncture. — Dr. DOWSE said if the galvanism kept the scrotum contracted its value might readily be conceived. — The PRESIDENT, in reply to Mr. Gould, said that the age of the patient did not enter into the question of his fitness for radical cure so much as the state of his constitution and the size of the hydrocele.—Mr. OSBORN, in reply, said that contraction of the scrotum was produced and maintained by the galvanic suspensory bandage. Although using it in many cases, it had produced no injury.

The PRESIDENT related a case of Epithelioma of the Tongue; removal by Buccal Operation. A man aged fifty-eight was admitted into the Royal Free Hospital on Dec. 31st, 1880. The growth was of eighteen months' duration, attributed to the irritation of a jagged molar tooth. He was also a great smoker. Last April the growth commenced to rapidly ulcerate, and his strength was much reduced by hæmorrhage. The tongue became enlarged, and a deeply excavated ulcer involved the right and base of the organ. The cancerous infiltration extended in the body of the tongue to the left side. There was considerable pain and tenderness. The submaxillary and upper right cervical glands were large, hard, and tender. Iodide of potassium was given in increasing doses without relief. On January 15th the following operation was performed. An incision was made from the angle of the mouth to the angle of the lower jaw, avoiding the parotid duct and exposing the base of the tongue. The facial artery was twisted, the tongue drawn forwards, and removed by the chain écraseur around the root of the organ, guided by the curve of two aneurism needles, introduced from beneath the tongue upwards in front of the epiglottis. The removal occupied twenty minutes. No hæmorrhage occurred. The buccal incision was closed with harelip pins. The patient made a good recovery from the operation. The submaxillary glands diminished in size, but the concatenate glands remained enlarged. The growth had presented the microscopical character of epithelioma. Both the patient and the tongue were exhibited.

Mr. ROYES BELL brought forward a case of Removal of the Tongue by Nunneley's Operation. The tongue shown was that of a man, aged sixty-nine, who was admitted into King's College Hospital, under the author's care, on Oct. 3rd, 1878, operated upon on Oct. 11th, and discharged on Nov. 13th. There was a large epithelial growth about the centre of the right side of the tongue, which was attended with the usual distressing symptoms. The whole of the disease, and almost the whole of the tongue, was removed by the submental operation. The strong wire loop of an écraseur was passed through the floor of the mouth under the chin, in front of the hyoid bone; the loop was then passed over the back of the tongue, which was drawn forcibly forward by means of a stout string passed through its tissue; the mouth was kept open by means of Mr. W. Rose's gag and the tongue cut off by the écraseur, the removal taking thirty minutes; it was followed by free bleeding, and stopped by tying the arteries in the usual way. This operation goes by the name of the late Mr. Nunneley of Leeds, and is well suited to the case. There are instances where the floor of the mouth being involved, the severer form, styled "Syme's," becomes necessary. —Mr. MASON referred to the importance of thoroughly freeing the tongue in any operation for its removal, and pointed out the unfavourable prognosis in these cases, few of whom lived more than twelve months after.—Dr. CHOLMELEY asked the President whether the patient referred to by him, from whom he had removed the tongue seven years ago, and who was now living, had exhibited any signs of glandular infection previous to operation, for he considered this an important question relative to prognosis.—Mr. OSBORN inquired if it was necessary to remove the whole of the tongue. —Mr. MORRANT BAKER considered the case a most successful one. He advocated a plan of operation adopted by him at St. Bartholomew's Hospital—viz., dividing the organ in the median line from its tip to the epiglottis, which, owing to the anatomy of the part, could be effected with little loss of blood. The advantages of this method consisted in the ease with which the severed parts could be grasped by the écraseur or the cautery applied; and by the mode of freeing the tongue the elimination of the disease was more readily secured. He laid stress on not trusting to the needle behind alone.—Mr. PEARCE GOULD asked Mr. Baker what kind of écraseur he used, and referred to the large proportions of deaths from lobular pneumonia due to the septic effect of sloughing, which frequently follows the operation. — Mr. BAKER said he used whipcord or wire.—The PRESIDENT pointed out the advantages of the écraseur, which injured the vessels more than a single wire would, and thus arrested hæmorrhage. Even did the operation not prolong life, it certainly ameliorated the distressing condition of the patient. In the case referred to by Dr. Cholmeley the cervical glands were not enlarged at the time of the operation, although the submaxillary were somewhat increased.—Mr. ROYES BELL replied.

Dr. RADCLIFFE CROCKER showed a case of General Psoriasis, illustrating the comparative result of Treatment by Turpentine and Chrysophanic Acid. The patient, a man aged forty-six, had never been entirely free from the disease for fourteen years; a soft cancer ten years before was not followed by constitutional disease, and the psoriasis presented the usual typical character of the now specific eruption. The disease was worse in winter; the last attack began in November last. With the exception of the lower part of the face and scalp, the middle of the back between the crest of the ilium and the line of the angles of the scapulæ, and the backs of the thighs, the eruption was so closely distributed that there was scarcely any interval of healthy skin; over the knees and elbows the patches were larger. The treatment adopted was: first swathing him in bandages soaked in oil for four days, to remove the scales;

the left half of the body was then rubbed with half a drachm of chrysophanic acid to one ounce of lard, whilst the right half was rubbed with two drachms of oil of turpentine to one ounce of olive oil. The strength of each preparation was increased every few days, until pure turpentine was applied on the right side, and chrysophanic acid, one drachm to the ounce, was used to the left; and in twelve days from the time this strength was reached the whole eruption on both sides had disappeared with the exception of a few spots on the shoulder. As far as rapidity of action was concerned there did not seem any advantage of one application over the other; there was a little tingling with the turpentine, whilst the chrysophanic acid produced staining of the clothes and skin. Dr. Crocker brought this case forward as an evidence of the success attending a penetrating stimulant to the skin, and believed that any stimulant of that kind was efficacious in removing the eruption of psoriasis; the only internal treatment was an alkaline expectorant, as the man had slight bronchitis, and towards the end some perchloride of iron. No arsenic was given. The case was under treatment thirty-three days.—Dr. DOWSE referred to the advantage of the treatment of psoriasis with india-rubber sheeting, and questioned the safety of turpentine applications.—Dr. GILBART SMITH had had a patient under his care suffering from marked psoriasis, whose previous attack had been treated by numerous methods, india-rubber sheeting among the number. A speedy removal of the eruption followed the daily application of an ointment composed of chrysophanic acid, half drachm to the ounce. A certain amount of conjunctivitis was present while under treatment, but gave no uneasiness.—Dr. GIBBON recommended the use of tar.—Dr. CROCKER replied he had never known strangury occur from the use of turpentine in this way over a large surface.

CLINICAL SOCIETY OF LONDON.

Partial Disease of the Nuclei of Motor Roots of the Fifth Nerves.—Quiescent Scirrhus of Breast.—Erythema and Herpes Iris.

THE ordinary meeting of this Society was held on Feb. 25th, Dr. Althaus, vice-president, in the chair.

Dr. HILTON FAGGE read notes of a case of Paralysis due to partial disease of the Nuclei of the Motor Roots of the Fifth Nerve. W. B——, aged forty-one, was admitted into Guy's Hospital on Oct. 18th, 1880, on account of an inability to close the jaws. He said that three months ago he began to experience difficulty in holding anything tightly between the teeth, and that afterwards he could not bite his food well. The loss of power gradually increased, until three weeks ago he became quite unable to bring his teeth together. He also had difficulty in swallowing, and liquids returned through the nose. The drop of the jaw was still slowly becoming more marked. He was a strong, healthy-looking man, but his expression was vacant, and his features had lost much of their play. This, however, was not due to any defect of the seventh nerves (for he could whistle a tune perfectly well), but to separation of the jaws. When he tried to bring the upper and the lower teeth together he could not do it; the temporal muscles could, in fact, be scarcely felt to contract, and the masseters acted very slightly. The excitability of these muscles to the continuous current was much impaired, and they were obviously wasted. Yet the lateral movements of the lower jaw performed by the external pterygoid muscles were normal. On inspection of the fauces, the soft palate was seen to move symmetrically during inspiration, but the left side of the palatine arch was dropped, and narrower than the right side. It appeared clear, therefore, that the case, which (so far as Dr. Fagge knew) was unique, was one of a partial lesion of the motor nuclei of the fifth nerves, comparable with bulbar paralysis, and with Mr. Hutchinson's "ophthalmoplegia externa;" and, as in the last-named disease, the cause was possibly syphilis, for the man had, twenty years previously, had gonorrhœa and a bubo, and his wife, to whom he had been married nineteen years, was never pregnant. Another noteworthy symptom was the presence of sugar, to the amount of 54·7 grains per ounce, in the urine, which was of specific gravity 1049. He also complained of slight occasional diplopia, and the muscles of the arms and the extensor muscles of the forearms were found to have a diminished capability of reacting both to continuous and to faradaic currents. He was ordered to take one-twelfth of a grain of bichloride of mercury and two grains of iodide of potassium, three times a day. Under this treatment he rapidly improved, and he refused to stay in the hospital after the 5th of November.—Dr. ALTHAUS said that such affection of the motor portion of the fifth nerve was rare; and the question to determine was whether the lesion were basal or central. The singular involvement of the third nerve pointed to the base; whereas the bilateral character of the affection was in favour of its being central. He had seen a case, obviously inflammatory, of bilateral affection of the whole fifth nerve. In that case the pterygoids were paralysed. There was also tinnitus aurium, which he attributed to paralysis of the tensor tympani, it being supplied by the auricular branch of the fifth. There was also paralysis of the palate. Was the pupil affected in Dr. Fagge's case? After section of the fifth nerve in the skull there is contraction of the pupil followed by dilatation, and then sluggishness.—Dr. DOWSE had not much doubt that the disease involved the fifth nerve; but the difficulty in swallowing, &c., seemed to point to involvement of the roots of the vagi and glossopharyngeal; and the slight loss of power in the muscles of the forearm was a further indication of the downward extension of the lesion. The condition resembled those due to pachymeningitis or bulbar paralysis.—Dr. POORE thought there was slight deviation of the tongue to the right side. Did the muscles give the degenerative reaction to galvanism or the ordinary reaction to faradaism?—Mr. GODLEE pointed out that the buccinator acted fairly well.—Dr. FAGGE, in reply, said that no increased susceptibility to galvanism was obtained. There was no mention in the report of tinnitus or of the condition of the pupils. He considered the case allied to bulbar paralysis, progressive muscular atrophy, and ophthalmoplegia externa, and that the change involved the nuclei of the motor roots of the fifth nerve.

Mr. J. W. TEALE (of Scarborough) read notes of a case of Quiescent Scirrhus of the Breast. A lady, aged fifty-three, a widow, noticed eleven years ago a small, hard, painful lump in the left breast. The surgeon whom she consulted advised its removal, and Mr. Teale, who saw her soon after, considered it malignant, and gave the same advice. All idea of operation was declined. The tumour gradually increased, becoming adherent to the ribs; the nipple was retracted and then obliterated. Pain, which was often excruciating, was relieved by morphia, taken up to four grains daily, and sleep obtained by chloral in increasing doses up to sixty grains. She became emaciated, feeble, bedridden, and apparently at death's door, living for two years on milk only. Eventually, the chloral having been discontinued, owing to the distressing nervous symptoms to which it gave rise, a gradual change in the symptoms took place. The bodily health began slowly to improve, whilst the tumour began to shrivel, the discharge ceased, and the pain gradually diminished. Mr. Teale reported that during the last five years the patient has remained well and fairly strong, and able to walk some miles daily. She has gradually resumed ordinary diet and modes of living, and takes less than half of a grain of morphia daily, whilst the present condition of the shrivelled breast-tumour was shown by a photograph recently taken, which Mr. Teale exhibited to the Society. Mr. Teale raised the question whether the extremely debilitated condition to which the patient had been reduced, and her enforced low diet, had not determined the retrogression of the disease.—Dr. ALTHAUS said no doubt such cases did occur; they were classed by Nélaton under the head of "retrogressive scirrhus."—Dr. C. T. WILLIAMS, alluding to the fact that chloral was abandoned because of the presence of severe nervous symptoms, asked whether these symptoms were really due to that drug. He had often given large doses without serious effect. An old gentleman of seventy-four, the subject of mitral disease, took half a drachm of chloral every night for six months without a bad symptom. In a case of spasmodic asthma he had given fifteen grains every four, and then every six hours, for fifteen days; the asthma was subdued, but a purpuric rash appeared.—Mr. TEALE said that it seemed to him that the chloral was the cause of the bad symptoms, which disappeared on its being discontinued.—Dr. ALTHAUS had recorded in the Clinical Society's Transactions a case where a patient took as much as 120 to 180 grains in the twenty-four hours, causing total destruction of appetite. The chloral was suddenly stopped without ill effects; but ultimately the patient recurred to the drug and died.—Dr. FAGGE pointed out the great difficulty there was in chronic cancer of discovering the epithelioid elements; and he had long thought those cases where hard masses or strictures occur—(e.g., in bile-duct or intestine), the disease was really malignant, although the epithelial elements were not visible in the mass itself. The existence of distinct secondary growths often settled the question. The burden of proof lay with those who asserted these were fibrous strictures rather than fibroid cancers.—Mr. GODLEE asked whether the condition of the axillary glands had at all altered.—Mr. WARRINGTON HAWARD said the photograph was suggestive of a long-continued growth which had undergone degeneration. Analogous cases were seen in cancer of the rectum, where the growth often exists a long time, and eventually becomes of fibrous nature. Had the arrest of the disease any relation to the prostration and inanition? His own impression was that it was better not to press food on cancer patients, lest the growth be stimulated. A lady seen by Sir James Paget, suffering from cancer of the breast, and taking very little food in consequence of becoming addicted to morphia, became emaciated and very weak. For two years and a half the cancer gradually ulcerated, until at last only a large open wound was left, showing no tendency to heal, but giving rise to a small quantity of foul discharge. At the end of five years from the commencement, another growth appeared in the opposite breast, which progressed very slowly for about another year. She was still taking morphia, but now began to take also large quantities of brandy. Coincidently with this the growth made rapid progress, infiltrated the skin, invaded the lung and pleura, and led to death. The practical inference was that it is better to starve rather than feed the subjects of malignant disease.—Mr. TEALE, in reply, said in his case the nervous symptoms and prostration disappeared on leaving off the chloral, but the morphia was continued. The symptoms in the case attributed to chloralism were those of incipient insanity. The axillary glands had remained in a perfectly stationary condition. The diagnosis of cancer was confirmed by Mr. Teale of Leeds, who had no doubt as to its nature.

Dr. RADCLIFFE CROCKER described four cases of Erythema or Herpes Iris, one of which had been shown to the Society at a previous meeting, and another was brought to the present meeting to show the scars which sometimes result from this affection. A wax model of a typical case was also exhibited. W. G——, aged twenty-three, a butcher, had suffered from three attacks, and though there was no evidence to show what led to the first attack, which occurred during a voyage to the Cape, subsequently errors in diet aggravated or determined an outbreak. His general health was good, excepting a tendency to constipation. The eruption appeared most abundantly upon the hands and feet, especially the fingers and toes, but other parts of the limbs, and now the lower parts of the trunk were sometimes affected. The lesions were symmetrical, though often one patch was nearly well before the corresponding one on the other limb appeared. Each began as a flat red papule about one-sixteenth of an inch in diameter, with a red areola of about half an inch. Sometimes a pustule appeared on the papule, which ruptured, and a brownish-pink zone appeared round it, and outside that a white one, the patch increasing by the formation of fresh rings varying from white to pink or bluish-red tints, and reaching to about the size of a florin; the rings then broke up, and the patch gradually faded, leaving a purplish-red stain, which lasted for some time. The eruption was attended with burning and itching, but the general health was unaffected. Dr. Crocker alluded to the other varieties of this affection. Thus, in some no central vesicle or pustule was formed, but only a flat papule, which became depressed in the centre, and concentric rings spread from that. On the other hand, there might be a large vesicle, or even bulla, in the centre, with concentric rings of vesicles, which gave rise to the name "herpes iris." The tint of the rings in all varied from white to various pink and bluish shades of red. These variations depended mainly upon the quantity of fluid effused into the tissues. In the child, which attended the meeting, the eruption began as rings of erythema an inch in diameter; in a few days these disappeared simultaneously with an outbreak of bullæ of large size, around which came a ring of vesicles, and the contents becoming purulent these dried into scabs, which left the deep disfiguring scars now visible. Speaking generally, the noticeable features of the affection were: (1) its tendency to recur, especially in the spring and autumn, and often in the same month in any one case; (2) to attack children and young adults of either sex; (3) to develop symmetrically, the hands and feet being especially attacked, though in rare instances it was universal; and, finally, to run its course in a few weeks, apparently uninfluenced by treatment.

Dr. F. TAYLOR read notes of cases of Erythema and Herpes Iris. — CASE 1. A man aged forty, previously in good health, was seized one day while at work with violent sneezing and watering of the eyes, and in the morning found his gums and palate becoming swollen, and could only open his mouth with difficulty. These symptoms subsided in two days and an eruption appeared. It commenced on the left thigh in the form of blisters, to the number of twelve or more, about the size of a shilling piece, containing a watery fluid. The following day it appeared on both legs and arms, and he had at the same time a burning sensation in his feet and pains in the joints. The eruption then spread to the head, face, and trunk, the abdomen being the only part spared. When seen on the eighth day of its appearance the eruption consisted of vesicles and bullæ of various sizes, and for the most part arranged in a circular manner, so as to include an area of comparatively healthy skin as in a ring of blister. Some such rings were formed of six to eight isolated small vesicles with clear contents; others of one continuous bulla of vesication of completely circular form, the contents being then mostly deep pink or purple. In many places the circles had coalesced and formed irregular figures, and some circles and patches measured as much as two inches in diameter. The bullæ were upon a slightly inflamed base. The face was much swollen in the early stage of the eruption. There was no itching, but only a burning sensation on its first appearance. He began rapidly to improve without special treatment. After becoming full of dark sanguineous fluid, the bullæ burst, the secretion drying into a dark scab or leaving an open ulcer. These ulcers were slow in healing, and have left several scars, reproducing more or less accurately the consecutive and ringed shape of the original bullæ. They are numerous on the arms, forearms, thighs, and legs. The duration of the bullous stage was about three weeks, but the healing of the ulcers took much longer. Two years have now elapsed, and there has been no recurrence.—CASE 2. A child aged five months, recently vaccinated. Ten days after the operation the eruption began as pimples on a red surface completely surrounding the vaccination crusts, and, subsequently, spots appeared on the arms, chest, abdomen, and back. The spots or patches were oval or circular, touching each other by their borders, but not running freely together, of bright pink colour, with deeper red, very narrow, more prominent margin. In the centre of many was a bright red spot or pimple, and vesicles formed both in the central papule and at the margin of the patch. The child was seen on three successive days, on the last of which the patches were fading.—CASE 3. A boy aged nine years, who was generally delicate and had suffered from cough and weakness for three months. He presented an eruption on the chest, abdomen, neck, back, and lower extremities, consisting of patches about half an inch in diameter, with a central yellow crust; around this was an elevated ring, and upon this again small vesicles. The vesicles dried up into crusts, and around them formed fresh rings of redness with new vesicles upon them; and their contents, at first serous, became purulent, and then discharged and formed scabs. When the crusts separated the skin beneath them had a brownish stain. The eruption lasted about six months. Dr. Taylor remarked that these might be regarded as three different forms of the disease known as erythema iris, herpes iris, or hydroa; and further defined by Mr. Hutchinson as a vesicular form of erythema multiforme. In the case of the infant it was distinctly a vesicating erythema papulatum, or circinatum; in the boy the vesicular characters were more marked; in the adult (Case 1) the vesicles appeared before the redness, a feature characteristic of hydroa according to Bazin. In the sudden outbreak, spontaneous disappearance, symmetrical distribution, and in the co-existing inflammatory disturbance of the joints, it also resembled cases described as hydroa. The large size of the bullæ would have suggested the name pemphigus, as pemphigus circinatus, or serpiginosus.—Dr. STURGE related a case recently under his care. The patient was a lad six years old, who had been ailing for ten days when first seen. He had a temperature of 102°, and at the end of six days in hospital numerous papules and vesicles appeared on the legs in the form of rings half an inch in diameter. The patches had a red base, surrounded by a circle of vesicles; in some places a distinct bulla formed. He had also a crop of herpes on the lips, a sore throat (with vesicles on the palate), and an attack of dry pleurisy. He recovered in three weeks.—Dr. C. T. WILLIAMS asked if the vaccination in one of Dr. Taylor's cases had anything to do with the disease.—Dr. B. O'CONNOR said pyrexia was unusual in these cases, and in his experience the rash was not generally symmetrical in the limbs, although often on both sides of the trunk. Herpes iris was rare on the trunk. He asked Dr. Taylor for his experience as to the value of arsenic in pemphigus, and mentioned the case of an infant who had been vaccinated a few months before, escaping the contagion of measles (with which other members of the family were afflicted), but becoming attacked with pemphigus.—Dr. T. C. FOX protested against the confusion existing with regard to the relations between the erythematous and vesicular and bullous affections. The latter were only stages of the erythematous inflammation; and Hebra was right in including the various phases under the head of erythema multiforme. Vesiculation was not common; herpes iris was always met with on the back of the hands and fingers, instep, and front of the knees; and was always combined with herpes facialis. It had a great tendency to recur, especially in the spring and autumn.—Dr. CROCKER, in reply, said symmetry was the rule in these eruptions; although there was often a delay in the appearance of the rash on the opposite side to its first appearance. He did not think any treatment influenced the course of the affection. Fever, especially in children, is a common symptom, but is transitory. He agreed with Dr. Fox that the distinction between the vesicular and erythematous rashes was only one of degree, but he did not think herpes labialis so invariable a concomitant of the vesicular form.—Dr. TAYLOR, in reply, said he did not think the vaccination in one of his cases had anything to do with the erythema. Arsenic did good in some cases of pemphigus; in others it was of no use. He gave it usually in the form of Fowler's solution. He thought the depth of skin affected, as well as the intensity of the inflammation, had much to do with the variety of eruption produced.

The Society then adjourned.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

AT a meeting of this Association held on Wednesday, February 16th, 1881, Mr. THOMAS EDGELOW, President, made a few remarks on taking the chair. After thanking the Fellows for the honour conferred upon him, Mr. Edgelow alluded to the late meeting of the General Council, and stated that the result of its deliberations was the condition and claims of the Dental Register. The conclusions arrived at (were there no hope of obtaining an amendment or repeal of the Act, or a distinct recognition of the status of the *surgeon* practising our specialty in the new Medical Act) could not but be regarded with dismay by all interested in the welfare of the profession. The Dental Act has now so signally failed as a practical measure that its very authors must, one would imagine, be heartily sick of it. It has even proved too comprehensive for them, and a great number of names, withdrawn from the Dental Register at the suggestion of the British Dental Association, are now to be restored triumphantly to the lists. In fact, he regretted to state that of the five thousand and odd names that have been entered on this Register, *one* name alone has been expunged by the Council. It was also settled by counsel's opinion that the Executive and Dental Committees have no power to originate proceedings for the removal of any name from the Register, but that all initiation of proceedings to effect this object must rest with the General Medical Council itself. Another point to which he wished to direct attention was, that only the purely dental qualification was allowed to appear on the Register. As long ago as December, 1878, one of the Fellows of the Association applied formally to have his surgical titles entered, but without effect; and now the refusal was pronounced by counsel to be only in harmony with the Dentists Act, and should contain no reference "to other qualifications or practice in either medicine, surgery, or pharmacy." Thus the Dental Register will be very simply and easily divided into two sections—one containing only the purely dental qualification, the other no qualification appended at all. Thus the surgeons, and those without qualifications of any kind, are to be left indiscriminately mixed up, and the licentiates are to pass as the only true representatives of the qualified profession. But while our Association has never failed to recognise that the licentiate has a distinct advantage over the unqualified practitioner, and while it recognises and strives at the general elevation of the profession that undoubtedly has arisen from the higher state of dental education resulting from the institution by the College of Surgeons of its examination in matters purely dental, its very name and constitution would forbid it to sit down quietly without protesting against such an anomalous state of things. It will now become a matter for the personal consideration of those Fellows of our Association, whether under these circumstances it would not be desirable for them (should they not have done so), to withdraw their names from the Dental Register, and to content themselves with their position on the Medical Register. What action should be taken by this Association at the present juncture will receive the careful consideration of the Council, and whatever form this action may take its action will certainly be to strengthen the bonds already happily existing between ourselves and the medical profession, of which profession we have always claimed to be an integral part; and we shall jealously watch, and to the best of our ability oppose, any action, from whatever source it may emanate, that would seek to loosen ties which we trust and believe will prove to be indissoluble.

Mr. E. T. M. PHILLIPS of Liverpool then brought forward the following cases:—Case 1 showed the models of the mouth of a boy aged fourteen, from whom the two roots of the first right lower molar had been extracted, connected with which was a small cystic tumour, the result of an alveolar abscess. Cases 2 and 3 were examples of supernumerary teeth. Case 4 showed the altered appearance of the upper laterals from enlargement of the basal eminences. Case 5 was a very curious condition occurring in the mouth of a young lady aged fourteen, where, on the left side, the canine and first bicuspid were missing, but were erupted and in normal position on the right. Case 6 was one of rare occurrence, and was an example of the transposition of the canine and first bicuspid. Mr. Phillips thought the explanation of this transposition might be accounted for probably in the early removal of the temporary canine, thus allowing the first bicuspid to come close to the lateral incisor, and that the permanent canine, when erupted, not having room, had descended between the two bicuspids. Case 7 was that of a child aged five, and showed the presence of the supernumerary teeth ranged in regular order with the others in the dental arch, and it was a question which should be considered as the supernumerary ones.

Mr. W. A. N. CATTLIN exhibited four upper Incisor Teeth, with absorption of fangs, which were loose, and extracted from the mouth of a young lady, aged only seventeen.

Mr. FRANCIS FOX brought forward an example of a Supernumerary Tooth, removed from the mouth of a boy, aged eight. The tooth was placed in the centre of the upper jaw, in the situation between the two central incisors, which he regarded as somewhat uncommon, and raised the question whether it was a supernumerary tooth in relation to the milk or the permanent dentition. His opinion was that it belonged to the permanent set, as such teeth, when occurring in connexion with the deciduous series, are generally found in the lower jaw.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES.

Miss K. G. Simmie, late of Edinburgh, bequeathed £200 to the Royal Infirmary of that city. Ripley's Hospital, Lancaster, becomes entitled, under the will of Mrs. Ripley, to the residue of the estate, by which the income of the charity will be raised to £12,000 a year. Mr. Charles Hargrave, late of Bayswater, bequeathed £2500 each to the Middlesex and the London Hospitals, £1500 each to St. Thomas's and Charing-cross Hospitals, £1000 to St. George's Hospital, £500 each to the Royal Free, St. Mary's, University College, King's College, Moorfields, Poplar, the London Fever, and the East London Children's Hospitals, and the Margate Sea-bathing Infirmary.

Reviews and Notices of Books.

Atlas of Pathological Anatomy. By Dr. LANCEREAUX and M. LACKERBAUER. Translated by W. S. GREENFIELD, M.D., with additional Plates drawn by Mr. W. HURST. London: J. & A. Churchill. 1880.

ENGLISH medical literature has been singularly deficient in works of the kind to which this volume belongs. The first atlas of morbid anatomy in this country was that of Matthew Baillie, issued in 1799; in 1827 Dr. Bright published, in his admirable "Reports of Medical Cases," many plates of renal and cerebral disease; in 1834 Dr. Hope and in 1835 Sir R. Carswell respectively issued illustrations of morbid anatomy, and of these perhaps Carswell's work remained the best known. From that time until the commencement of their atlas by the New Sydenham Society no similar work has issued from the English press, the costliness of production of such works being a great barrier in the way of their more frequent publication. Pending, then, the publication of a work wholly based upon English material by English artists, we may heartily welcome this translated edition of Lancereaux's well-known atlas, and may thank Dr. Greenfield for having undertaken the task of editing it. He has thought fit to make some additions to the original work, illustrating many conditions, especially in pulmonary disease, which had been inadequately represented by M. Lancereaux. These additions comprise ten plates, executed with his usual fidelity by Mr. W. Hurst, whose drawings, for delicacy and finish, compare very favourably with many of the more highly coloured and somewhat exaggerated productions of the French artist.

A glance through the volume shows us that M. Lancereaux has paid especial attention to conditions often passed over by others. He figures, for instance, lesions of lymphatic glands, kidney, heart, lungs, membranes of brain, muscle, and bone, as well as the gastric and hepatic disorders attributable to alcoholism. Amongst other novelties he represents uræmic gastritis (with pyloric ulceration) and uræmic enteritis; but he only gives one figure—and that not a very good one—of typhoid enteritis, a deficiency which the editor has done well to supplement. The rare form of new growth known as adenoma of the liver is amply illustrated. A specimen of blood containing bacteria (? bacilli) from a case of malignant pustule is represented. We have also figures of the rare condition, almost unique in our experience, of tubercular endocarditis. M. Lancereaux represents a dissection of the cardiac plexuses in a case of angina pectoris, and devotes certain plates to represent the lesions of gout (in which we see he includes one of deposit on the aortic valves) and lead poisoning. On the whole, we think that there are certain defects as well as superfluities in the distinguished French pathologist's work.

Dr. Greenfield has, as we have said, done much to remedy the defects. The illustrations of phthisical changes, of chronic pneumonia, &c., which he gives, admirably supplement the work in the parts where it is most deficient. Other additions include illustrations of organs in Hodgkin's disease and leucocythæmia, as well as drawings of ulceration of the intestines in enteric fever, dysentery, and tuberculosis, scarlatinal nephritis, nutmeg liver, and fungating endocarditis.

In its present form the atlas will supply a long-needed want, and although in some respects (especially in the histological representations, many of which are unworthy of the work) it is still imperfect, it is certain to be much appreciated, and will, we hope, reward the enterprise of those who have undertaken its issue. Should this be the case, we may also look forward to the time when the stores of material accumulated by our own pathologists will receive similar illustration.

Fits, their Diagnosis and Immediate Treatment. By JOHN H. WATERS, M.D. &c., Surgeon to the C Division of the Metropolitan Police. London: J. & A. Churchill. 1879.

THE author has been led to write this little work, not with any idea of giving anything new to the profession, but to set forth the most prominent symptoms of those affections coming under the notice of police surgeons, in which insensibility or convulsions occur. Dr. Waters divides his cases into two tabular divisions: the first, cases of coma in which danger to life is imminent; the second, cases of coma not intense, in which no danger to life is expected to arise. The first division is further subdivided into two classes—(*a*) those in which the symptoms develop suddenly and severely, and where the coma is intense, in this group is included rupture of cerebral aneurism, severe injuries to the head, and sunstroke; (*b*) those in which the symptoms are slower in their advent, with more or less loss of insensibility. This group includes uræmic convulsions, sanguineous apoplexy, embolism, opium poisoning, &c. The second division likewise can be divided into two groups—(*a*) where sensibility is suddenly lost and the patient cannot be roused, and (*b*) where the sensibility is not lost suddenly, and the patient can be roused. In the first group are included epileptic and "excentric" convulsions, in the second alcoholic intoxication. These tables are undoubtedly useful, but experience teaches us that it is impossible to draw a hard-and-fast line in the majority of instances that come under observation, and the difficulty is increased by the case being generally complicated by other conditions.

OUR LIBRARY TABLE.

Midwifery for Midwives. By J. E. BURTON. London: J. and A. Churchill.—This little work is a translation of the Official Handbook of Midwifery for Prussian Midwives. The book was written by Professor Litzman of Keil, and submitted to a committee of experts. The name of the author alone is a sufficient guarantee for the excellence of the work. It treats the subject fully, and contains a clear account of the duty of the midwife to the woman during pregnancy, labour, and the lying-in period, as well as in the management of the child. Regular or natural labour is well and clearly explained, and the means whereby irregular labour can be recognised, and the *duties* of the midwife in all cases, are distinctly stated. We know of no work better suited for midwives than the one before us. We would add that the translator has done his part on the whole well, and has rendered the book into simple and clear English.

Questions on Magnetism and Electricity. By F. W. LEVANDER. London: H. K. Lewis. 1880.—This is a series of questions culled from the papers set at the Preliminary Scientific and First B.Sc. Examination of the University of London. It will doubtless prove of great service to many candidates, not only on account of the *matter*, but for the *manner* also. Many students fail from a want of knowledge of how to put their answers concisely into words, and from a cursory inspection of this little book, Mr. Levander appears to us to have answered the questions at once correctly and concisely.

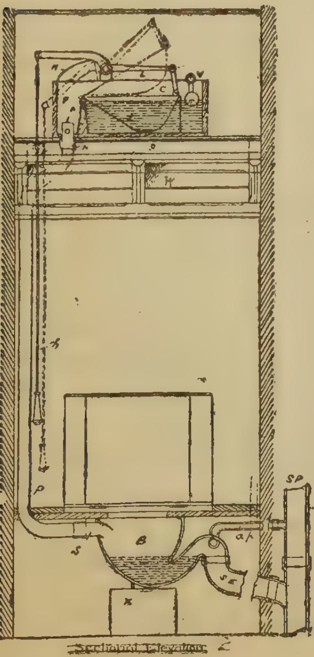
Atlas of Skin Diseases. By LOUIS A. DUHRING, M.D., Professor of Skin Diseases in the University of Pennsylvania, &c. Part VIII. Philadelphia: J. B. Lippincott and Co. 1880.—We have received the eighth part of this high-class atlas containing, as usual, four plates. Dr. Duhring has here selected for illustration the papular variety of Erythema multiforme as it appears affecting the backs of the hands every spring; a characteristic Tubercular Syphiloderm of the side of the scalp, face, and neck; an example of Nummular and Circinate Psoriasis of the back; and the chronic scaly condition of Tinea tricophytina of the scalp, neck, and face. We have so often expressed our appreciation of the marked success which has attended Dr. Duhring's efforts and we criticise the plates by so high a standard, that we almost shrink from saying that in Part VIII. there seems to us to be a slight falling off in excellence of execution. The subjects, however, are confessedly difficult. In the well-written letterpress accompanying the plates we see that Dr. Duhring employs the term Herpes iris so as to include all the vesicular varieties of Erythema multiforme.

Archives de Neurologie. Edited by MM. CHARCOT and BOURNEVILLE. No. II.—It is not every addition to medical periodical literature which can be welcomed as important and useful, but such is certainly the case with this French journal of Neurology, which fills a distinct want in the medical literature of France. It is to be published quarterly. In the second number, which is before us, there are three original articles: one on Subacute Parenchymatous Neuritis, by M. Gombault; a contribution to the Pathology of Tremor, by MM. Debove and Boudet; and an account of Epileptic Dementia, by MM. Bourneville and D'Olier, with a description of microscopical changes in that condition by M. Brissaud. About sixty pages are occupied by an analysis of recent papers on the Physiology, Pathological Anatomy, Symptoms, and Treatment of Nervous and Mental Diseases.

Note-book of Materia Medica, Pharmacology, and Therapeutics. By R. E. SCORESBY-JACKSON, M.D., F.R.S.E. Fourth Edition, revised and brought down to the present date, by Dr. FRANCIS W. MOINET, Lecturer on Materia Medica and Therapeutics, Surgeons' Hall, Edinburgh. Edinburgh: Maclachlan and Stewart.—This well-known book deserves to be even better known. It combines the most useful and important part of the British Pharmacopœia, with therapeutical notes, not bald and heartless, but sound and really suggestive of investigation, experience, and that equally rare quality—proper faith in the action and uses of medicines. We heartily commend it to students and practitioners.

New Inventions.

THE SHREWSBURY VALVELESS WATERCLOSET AND WASTE-PREVENTER.



THERE may be seen in the Parkes Museum at University College a very excellent closet, the invention of Mr. W. White, F.S.A. The great merit of Mr. White's closet seems to us to be its simplicity, and from seeing it in action we are in a position to state that it works effectually. A reference to the woodcut will explain its construction. The basin (*B*) is composed entirely of earthenware, and is fixed upon a block (*x*). The syphon is supplied with an air-pipe (*a p*) going from its highest point, and the discharge is through a curved pipe into the soil-pipe (*sp*). So far there is considerable resemblance between the "Shrewsbury" and Bostel's closet. The water-supply for the closet is from a special cistern (*c*) raised five feet above the basin and filled through a ball-valve (*v*). In the cistern is a receptacle capable of holding two gallons of water, which can be tipped by the action of the levers (*H L*) so as to discharge its contents instantaneously into the funnel (*F*), and through the funnel into the two-inch supply-pipe (*P*). This supply-pipe is furnished with a "spreader," which is fixed exactly opposite the aperture of exit of the basin. The mode of action is simple. The closet having been used, a pull is given to the handle shown in the figure, and instantaneously the two gallons of water rushes violently down the service-pipe and flushes the basin forcibly and effectually. The tip-tray is soon filled again, and a second flush can be given if necessary. The closet has the advantages (1) of being very simple, (2) of having a separate water-cistern, (3) of preventing waste of water, (4) of being efficiently ventilated, and (5) of being moderate in cost.

A NEW PORTABLE STETHOSCOPE.

WE have received from Messrs. Salt and Son, of Birmingham, a portable stethoscope, arranged by Dr. Sutherland. The stethoscope divides into four separate pieces—the ear-piece, the chest-piece, and two hollow rods, forming the tube. These four pieces, when screwed together, form an ordinary stethoscope; when separated, it is intended that the two rods should be inserted transversely through the chest-piece and through the ear-piece, so that the whole stethoscope again appears as one piece, but so flat in shape as to be easily carried in the breast- or tail-pocket of a coat, thus doing away with the usual method of conveying the instrument in the hat. A brief trial of the instrument has proved that although it conducts the cardiac sounds as well as the ordinary stethoscope, it is less useful for pulmonary auscultation. The peculiar construction of the chest-piece necessary for the purpose above described may have some effect on this result. The idea is an ingenious one, and certainly the instrument is portable enough, although, when put together, rather ungainly and clumsy-looking.

EUKNEMIDA BOOT-SOLES.

OUR recent annotation on the subject of boots, and the attention we drew to the fact that the chief source of danger in getting "wet in the feet" was owing to the evaporation from the saturated absorbent sole, have given rise to some suggestions. The patent Euknemida soles are the invention of Mr. W. H. Smith, of High-street, Birmingham. Their mode of preparation is as follows: The soles are soaked in cold water, and are covered on both sides with pure tallow. After an interval of some time they are placed between dies cast to the shape of the sole of the foot, and are then subjected to an hydraulic pressure of 150 tons. This has the effect of rendering the leather exceedingly dense and of saturating it with grease. The cost of the process is small, and we believe the result to be satisfactory. We placed a pair of boots with Euknemida soles in water, so that the soles only should be in contact with the fluid; after fourteen hours' immersion we found that the boots were not in the least damp on the inside, and had not appreciably gained in weight, and that when the superficial moisture adhering to the surface of the sole had evaporated, the soles remained perfectly dry. From the result of this test, we believe that the soles are waterproof, as alleged. They are said also to be more durable. Apart from the impregnation of the leather with tallow, the compression would, probably, increase their power of damp-resistance, and of wear. When the poet Gay said in his "Trivia, or the Art of Walking the Streets of London,"

> "Let firm well-hammered soles protect thy feet,
> Through freezing snows, and rain, and soaking sleet,"

he was ignorant of the value of the hydraulic press for attaining the same end. The word Euknemida is not, we think, well chosen. It is of Homeric origin, and was applied by the father of poetry to the "well-greaved" Greeks, and cannot, in any way, be applicable to the "well-greased" soles of Mr. W. H. Smith.

INDIA-RUBBER GLOVES FOR POST-MORTEM EXAMINATIONS.

WE have received from Messrs. Cow and Co., India-rubber Works, Streatham-common, a specimen of their gloves for post-mortem examinations. They are very well made articles, of the thinnest film india-rubber, purposely made as thin as is consistent with due strength, so as to interfere as little as possible with the sense of touch, which they leave almost normal. They are easily put on and taken off. Several sizes are made. To practitioners, for keeping their hands free from smell and contamination in post-mortem examinations, they will prove very valuable.

THE WELBECK POISONINGS.

OUR readers will remember the curious series of poisonings, in some instances fatal, which occurred at the time of a sale on the Duke of Portland's estate at Welbeck, Notts, in June of last year. It was suspected that they had been caused by some of the provisions used for purposes of refreshment during the sale, and suspicion fell upon certain cooked "American" hams which had been used. The Local Government Board, appealed to in the matter at the time, commissioned Dr. Ballard of its Medical Department to make inquiry into the source of the poisonings, and the report of the results of his inquiry is now before us. The report does not add much to our knowledge of the general facts of the case as they were made known during their occurrence in the local press, but it presents us with a clear, connected account of the occurrences, and throws a new and unpleasant light upon their source. Dr. Ballard obtained more or less complete accounts of seventy-two cases of poisoning, chiefly characterised by much and peculiar diarrhœa accompanied with marked intestinal irritation. Of these cases four died in a state of collapse. Dr. Ballard was able to secure portions of the meats, and particularly of the hams, in use on the day of the sale, and his general conclusion from the observed facts was that the ham was in fault. The meats were submitted to Dr. Klein, and the results of that gentleman's examination are so important that we give them in Dr. Ballard's own words:—

"1st. The absence of trichinæ in the ham was established.

"2nd. The presence in all three portions of ham—the raw ham and the cooked ham, both that which had been and that which had not been exposed to sewer air—of a species of bacillus, with sporules of the same, was demonstrated. The bacillus threads and sporules were in connexion with the muscular fibre and in the intermuscular tissue.

"3rd. Bacillus material from the raw ham and from that portion of the cooked ham which had not been exposed to the sewer air, was successfully cultivated in the incubator. Cultivation was not attempted with the ham and the mutton that had been exposed to sewer air.

"4th. Experiments upon animals, dogs, cats, mice, rats, rabbits, and guinea-pigs, by feeding or inoculation, or by both methods, were made both with material from the hams and with the cultivated material, with the following general results—viz., (*a*) The experiments made with the portion of ham that had been exposed to the sewer air, and with the mutton similarly exposed, produced only negative results. (*b*) The experiments made with the raw ham and with the portion of cooked ham not so exposed, produced in all but a few instances positive and remarkable results—viz., disease in the animals experimented on. (*c*) The experiments made with the raw ham were more uniformly successful than those made with the cooked ham. (*d*) The experiments made with cultivated material gave in all cases positive results. (*e*) The morbid condition produced in the animals, and found on post-mortem examination, was most uniformly pneumonia (in one instance with pleuritis) or pulmonary hyperæmia. In some, hæmorrhage into the pulmonary tissue was observed. In some, there was hæmorrhage into the tissue of the liver, or the organ was found enlarged. In some the spleen was found enlarged or congested. In three instances peritonitis, slight or severe, was found. Two dogs fed and inoculated with the cooked ham, and killed on the eighth day (one having suffered from colic on the first day of feeding), exhibited after death evidence of severe desquamative hyperæmia or inflammation of the stomach and intestines, the contents of which contained bacilli and a few pus-corpuscles. Bacilli were found in the blood of two white mice which died twenty-four hours after having been fed and inoculated with material from the raw ham; but no bacilli were discoverable in the blood of two other mice inoculated with this blood, although, when they were killed on the second and third days respectively, they both were found to have severe pneumonia with enlarged liver and large congested spleen. Nor were bacilli found in the blood of four other animals in which they were sought for after death.

"5th. In the kidney of W. W—— there were discovered evidences of parenchymatous inflammation, and the afferent arterioles and capillaries of the Malpighian corpuscles were found plugged with emboli formed of masses of bacilli.

"In these observations and experiments we have a clue to the solution of the difficulty, which the ordinary methods of inquiry failed to furnish. In two hams taken indiscriminately out of the same consignment there was found a *living parasitic thing*, capable of spreading by its growth and reproduction through the material in which it was found, and *capable of producing disease in animals into whose system it was introduced; capable also of growth and reproduction within the system of these animals.* Taking into consideration that the fact that a number of persons who ate of ham of the same consignment suffered from disease induced by such eating, and the further fact that in the kidney of one of them large numbers of bacilli (similar to those found in the hams experimented with) were found, it appears reasonable to infer that some of the hams of that consignment were similarly affected with the parasite, and that *either the parasite itself, or some virus essentially associated with it, was the active agent in the production of the diseased condition* observed in the human subjects of the epidemic, and in the animals which were experimented on by Dr. Klein.

"There are two difficulties in the way of accepting this explanation. There is, first, the fact that many persons who had partaken of other hams of the same consignment, in some instances day after day, altogether escaped disorder; and, secondly, the fact that part of the same ham which in Dr. Klein's hands produced disease in dogs and rabbits, had apparently been eaten with impunity in the hotel. The first of these difficulties does not seem to deserve much weight. It is not likely that every ham consumed at the sale was affected in the same way and to the same degree, that cooking had operated alike upon all portions of the hams, and that all who ate of the hams were alike susceptible to the injurious influence. So some of the consumers might be expected to escape. The second difficulty is perhaps more serious; but, if allowance be made for the unequal operation of heat upon the thicker and thinner portions of a ham; for the thinner portion being that eaten at the hotel, while Dr. Klein experimented with the thicker and presumably less cooked portion; and for the fact that Dr. Klein got even from this portion less uniform results than he got from a raw ham; there would not seem to be any great difficulty in understanding how people at the hotel may with impunity have eaten portions of a ham which really did contain material capable of producing disease. The escape of these people, then, does not count for much against the conclusion indicated by Dr. Klein's affirmative results."

THE LANCET.

LONDON: SATURDAY, MARCH 5, 1881.

POSSIBLY — we might say probably — the difference of capacity between a child born of parents and grandparents who have never been educated, and one bred from a stock which has been duly trained to intellectual exercises, is the difference of what we call brain-power as exhibited by two organs, one of which consists of cells or molecules endowed with an inheritance of "capacity" to be taught, while the other is composed of elements which have not reached the evolutionary status of being, so to say, educable. The physical basis of mind is undoubtedly capable of improvement by the developmental force of culture in successive generations. There is, however, a reverse to this view of the question, and it not less clearly and certainly points to the conclusion that the process of development by education may be carried so far as to destroy or exhaust the intellectuality which it is desired to exalt and perpetuate. The children of a stock which has been highly cultivated during several generations not unfrequently exhibit an instability of mental temperament which readily degenerates into a neurosis. This is especially notable in the cases of males in a family remarkable for the culture of its female members. The point — evidently one of the deepest interest — is strangely overlooked or wilfully disregarded by those psychologists and physiologists who lend the countenance of their scientific experience to the vague and mischievous hypotheses propounded by the promoters of the higher education of females and of women's rights.

In the ordinance of nature the female is endowed with a force tending to the reproduction from her arrested or suppressed organism of the perfect organism of the male. It is essential to the accomplishment of this physiological task that the female should be trained for the development of *capacity*—that is receptivity—as a cerebral property, rather than impressed with the particular bias of education in a special class of subjects, or on formulated lines. The distinction indicated is not fanciful but actual, and may be directly inferred from the lessons of experience. The male children of mothers who have been distinguished for *special* intellectual attainments are not, as a rule, remarkable either for their brain-power or the mental work they achieve; whereas the male children of mothers who have been notably characterised by *general* intelligence, without special talents, are commonly distinguished for intellectual ability. Experience seems to show that special brain-*work*, properly so called, on the part of the mother, exhausts the energy of brain-development—or reproduction—which, if conserved, would express itself in the mental perfection of her male offspring. The operation of the law of "development by work"—universal in its application under normal conditions—seems to be suspended when the work done is the result of a concentration of energy, by which force is drawn off from centres other than those thrown into special activity. It follows that the higher education of women is racially—whatever it may be in the case of the individual—an economic mistake.

There can be no question as to the possibility of educating women to the level of men on special lines. The total amount of cerebral tissue available for the production of a highly educated mind-organ is not so great in the case of an average female as in that of an average male. The cells or molecules ready to be impressed or combined—as the constituent elements of organised brain-substance must be impressed or combined to produce *positive* intellectuality—will be less numerous in the case of the female than in that of the male; but the greater pliability of the female constitution seems to render its component parts peculiarly susceptible of influences directing its powers into any particular channel. It is therefore in no sense — physiologically — surprising that women should excel in the intellectual exercises proper to men. Meanwhile the possible is not always the prudent; and those who, forming a hasty judgment based on appearances, conclude that because young women can achieve distinction in the pursuits of a university career, they ought to be allowed to do so, would do well to study the facts of heredity in the light of history and experience. When the subject comes to be investigated by this method, it will, we are convinced, be found that the course on which we are entering, and the policy to which we are committing ourselves in this country, are both unsatisfactory and, so far as the race is concerned, unsafe. For the sake of a little ephemeral distinction the feminine stock is being placed in jeopardy, and in the future it will be found that the totality of mind-weakness and mental disease has been augmented. Woman's mission is not, in any degrading sense, inferior, but it is complementary, to that of man; and not only her health and happiness, but the prosperity of the race as a whole, are directly dependent on the integrity with which the female discharges the duty that nature has devolved upon her in the economy of development. It is not a question of power, but of purpose; and those who have egged women on to overstep the boundary lines of the path marked out for them are not only doing wrong, but working mischief, of which the consequences will be apparent later on, when the time to remedy the effects of this evil counsel is past. Our appeal must now be to the observation and experience of the educators of youth and the students of national and intellectual history.

◆

SIR TREVOR LAWRENCE will receive the thanks of all men who love what is sound, whether in or out of the Scotch medical corporations, for his opportune question in the House of Commons on Monday last. The College of SYME, and LISTON, and FERGUSSON, not to say of the WOODS and the GAIRDNERS, has more to gain than to lose by the exposure of a system so worthless as that of granting qualifications that should be an honour and a distinction on the ground of holding the lowest surgical qualifications, and granting these possibly *in absentiâ*, and on conditions essentially pecuniary. It is many weeks since we explained and exposed this system. We have contemplated its exposure for a much longer period, but have deferred it partly in the hope that the College itself would take steps to free itself of a system so indefensible and discreditable. But not a word has been uttered by the College in refutation of our charges that its Fellowship can practically be *bought*, and bought *in absentiâ;* and that the purchaser of a Fellowship, procured *in absentiâ*, may compete for a Hospital appointment in London on the same footing as a Fellow of the sister colleges by arduous examination, or may go to a colony with the ambiguous letters F.R.C.S.E. after his name, and pass easily for something that he is very far from being. If any friend of the Edinburgh College, or of the other Scotch corporations—for we regret to say that they are all involved in this honourless system of trade in honours—thinks it ungenerous in us to have stirred up this muddy pool, we can only reply that it is very hard to leave such work to be done in the advanced year of 1881. Fifty years ago such reforms would have been more opportune. But that they should still remain unaccomplished is the condemnation of the whole weak system calling so loudly for legislation.

Nothing could be more satisfactory and complete than the exposure and the confessions contained in the question of Sir Trevor Lawrence on Monday, and the answer of Mr. Mundella. The very defence—if such it can be called—of the College is a condemnation. The College informs the Vice-President of the Council that the Fellowship, which is to be had without examination, and even *in absentiâ*, is not a licence or qualification, but is a distinction! Which is the less creditable act, to sell a licence or a distinction? Surely, to sell a distinction, as likely to mislead more gravely! If it is wrong to lead the public to believe that a man is qualified, it must be more wrong to make him believe that he is highly qualified. Next to the public, the members of the profession have the best right of complaint, when a practitioner flaunts these ill-gotten distinctions as a means of conveying the impression that he has achieved feats of study and examination beyond those of his brethren. The answer given by Mr. Mundella supplies another and a very striking illustration of the working of the Medical Council, of which we have given many before. Let us see how the Medical Council answers the charge suggested by Sir Trevor, that a system of granting degrees *in absentiâ* has gone on without remonstrance or representation from the Medical Council. The Council says that in the year 1859 it was decided, "that in the opinion of the Council, for the future no licence or degree should be given by any of the bodies without examination." Since that time the opinion of the Council has been entirely disregarded by the bodies, and the Council has in no practical way revived or pressed the question. It has thus given another signal instance of its impotence and of the futility of its Recommendations. It is gratifying to be told by Mr. Mundella that this subject will form part of the inquiry which it is now understood to be the intention of the Government to institute into the working of the Medical Acts. The scandal can scarcely survive the exposure of Monday. The House was full in every part, and neither the Scotch Corporations nor the Medical Council can feel proud of their appearance on the occasion.

The action of anæsthetics upon the various forms of reflex action has been systematically investigated by Professor Eulenberg, of Griefswald. He finds that, neglecting slight differences, certain types of action may be distinguished. Certain anæsthetics (as chloroform) cause an initial, very transient, augmentation of some reflex actions; as, for instance, the "patella reflex" in dogs and rabbits, and then a progressive diminution, and disappearance of the reflex actions, in which it is noticeable that the patella reflex disappears earlier than the corneal reflex. The latter is lost at the same time as myosis and rigidity of the pupil occur. Conversely as the effect of the anæsthetic is passing off, the corneal reflex appears considerably earlier than the patella reflex. The same sequence is observable in the human subject during the induction of anæsthesia. The nasal reflex remains much longer than the corneal reflex, a fact which agrees with some observations made by Rosenbach on the natural sleep of children; it is only in the deepest hypnosis that the nasal reflex disappears. The cessation of the patella reflex is a convenient indication that the degree of anæsthesia is sufficient for surgical purposes.

Other anæsthetics, as ether, and some other ethyl compounds, cause an increase in the tendon reflexes, which often amounts to an extreme degree, and continues for a considerable time after narcosis is complete. The corneal reflex, in anæsthesia from ether, is weakened only at a relatively late period, and is rarely completely abolished.

The double chloride compounds — ethylene-chloride, ethylidene-chloride, and methylene-chloride—diminish the reflex actions in rabbits and dogs, and the corneal reflex always disappears sooner than the patella reflex, and conversely the latter always reappears sooner than the former. It is worthy of note, in this connexion that, according to Liebreich, these agents have a primary action on the sensory cranial nerves; and also that, according to the observations of Eulenberg, in asphyxia the corneal reflex disappears some time before that of the patella. Some anæsthetic compounds, as bromethyl, have only a slow and slight influence on reflex action; the patella reflex is slowly lessened without preceding increase, and the corneal reflex lessens later, and is rarely completely arrested. The action of bromethyl is thus similar to that of ether, but feebler.

The state of the various reflex centres appears to stand in no definite relation to the condition of the psycho-motor or psycho-sensory centres. The depth of narcosis, the condition and degree of the anæsthesia, are in no way related to the condition of the reflex action. The order of affection of these centres is different in the case of different anæsthetics; so also is the action of the various narcotic drugs. An injection of half a gramme on dogs and rabbits has little influence on the reflex actions, and an injection during the course, or before the action, of an anæsthetic has no influence on the effect of the latter. In individuals who take morphia habitually, even when under the influence of the largest doses, the tendon reflexes are unaltered. Chloral hydrate, given to rabbits in doses of a gramme and a half, by subcutaneous injection, has an action similar to chloroform, but without causing any primary increase. In an advanced stage of narcosis the patella reflex gradually lessens, while the corneal reflex persists, although in lessened degree, in cases which are not fatal. Bromide of potassium, administered to guinea-pigs subcutaneously, in doses of one to two grammes, causes at first an increase, and then a gradual diminution, of the patella reflex. Bromal-hydrate and bromide of quinine have no definite action, if cases are excluded in which their action is fatal. If they cause death by producing asphyxia, the corneal reflex ceases, as a rule, before the patella reflex; the latter disappears only before the occurrence of exophthalmos, dilatation of the pupil, and the terminal convulsions.

◆

OUR public health legislation appears to be getting more and more paradoxical, if, indeed, this be possible. At one and the same time its method of procedure is, perhaps, the most careful and the most reckless in existence. When directed to general measures, it is approached equally by Members of Parliament and by Cabinet Ministers with a caution and hesitation and dread of encroachment upon the freedom of action of individuals which, however consistent with the general spirit of the Constitution, is at times too apt to frustrate the best intended provisions for the public welfare. But when directed to local measures, it is pursued with a recklessness wholly inexplicable to the uninitiated, and which to them appears not unfrequently to stultify the general measures. The time seems to have come when Parliamentary procedure in respect to local measures involving public health provisions should receive the consideration of the Legislature, with a view to its revision and to its being brought more into accordance with the principles which govern procedure in respect to general measures.

We are induced to make these observations in view of certain local Bills introduced into Parliament this session. These Bills are not considered by a Committee of the whole House, but by a particular Committee appointed by the House, and if approved by this Committee are passed by the Legislature, seemingly without further consideration, and become law. Now, several of these Bills—Salford and Lincoln, for example—contain provisions for giving the Local Authority further powers than those contained in the Public Health Act, 1875, of dealing with infectious diseases, with a view to prevention, which overpass even the powers conferred upon the Central Government in the old Quarantine Act, which are as unlikely to be of practical avail as the powers of that Act, frustrating themselves by their own stringency, and which tend to recreate that insensate fear of infection which characterised the populations of the Middle Ages in face of plague—a fear which it is well known overrode every social and moral consideration, and, under the influence of the mere brute instinct of self-preservation, intensified the very evils which the measures of quarantine were designed to prevent. We have more than once raised a warning voice against this certain result of the existing, and we fear growing, tendency of local authorities to construct schemes for the effective control of the spread of infection, founded chiefly on theoretical views of *possibilities* of contagion; and suggested that a more careful study should be given to the history of quarantine in its efforts to this end. But there are other and singularly grave social considerations in the proposition to give almost absolute control over the actions and movements of the members of a family in which an infectious disease may appear, which should be dealt with by Parliament at large, and not by a small committee of its members.

We sympathise fully with local authorities and medical officers of health in their anxious desire to secure powers giving them fuller control over the dissemination of infectious diseases, but we deprecate the multiplication of measures which are mere "paper plausibilities," such as those of quarantine, and which involve such absolute dislocations of family, social, and industrial life as are now contemplated, and have in a few instances been permitted by Parliament. Any large exercise of these powers we believe to be impracticable—if, indeed, such exercise has ever been contemplated; and the necessary complement of them, in the provision to be made for the sustenance and avoidance of pecuniary loss by the persons subjected to them, are so imperfect in our estimation that the measures are certain to break down under trial, to the immeasurable injury to public health administration. There must be a limit to measures for the arrest or control of infection; and that limit is approached perilously near, if not exceeded, when powers are sought which would at the same time arrest the food-earning powers of the members of a community. After all, there are even greater evils to dread in a community than the spread of infection; and it is well to remember, in legislating for the avoidance of sickness and death, that the first consideration is the maintenance of life, and this at a somewhat higher level than Poor Law, municipal, or eleemosynary help contemplates.

Another and equally important subject with reference to this legislation on public health matters in Committee refers to questions of building. A glaring instance is here supplied by the Leicester Improvement Bill now before Parliament—or rather before a Committee of Parliament. There is probably no town in England where it is more necessary that the regulations of buildings should be subjected to careful regulation than Leicester. Under the Public Health Act, 1875, local authorities may make by-laws for this purpose with the assent and approval of the Local Government Board. To assist local authorities in their judgment in this matter, it is well-known that the Local Government Board have issued a series of by-laws as to new buildings which, as carefully explained in a circular letter, have two objects in view—namely, first, precision of provision, so that the house-owner knows precisely what he is called upon to do under the law, and is relieved from the crotchety action of local authorities when the matters were left to their discretionary judgment—a judgment which has been found by experience to be the source of endless mischief from the necessary changes in the individual members of the authorities; and, secondly, a careful and complete rendering of the law and practice on the subject. In this latter respect the model building by-laws are, it must be said, unique. Now, if the Leicester Improvement Act should be approved by the Committee of Parliament in its present form, it will traverse for this locality all that the Local Government Board has been attempting to achieve in the matter of building regulations under the Public Health Act, 1875, and leave the citizens of Leicester at the entire mercy in this important matter of their municipality and its surveyor for the time being. This has happened in other localities, and Parliament has not hesitated through its Committee on Bills thus to stultify its action in general measures.

Surely this cannot be necessary. Localities may have their peculiar requirements, but there are certain general principles which apply to all localities, and these cannot be tampered with in public health matters without detriment to the cause of public health generally.

◆

A BILL, embodying the provisions of the Alkali Acts of 1863, 1868, and 1874, with some further provisions, and an extension to some other chemical works, has been introduced into the House of Lords by Lord MELDRUM. The Royal Commission on Noxious Vapours reported in 1878, and Bills founded on the recommendations of this Commission were introduced in 1879 and 1880, only to fall with the other "innocents" at the end of the session. There was but little difference between these two Bills. Each was supplementary to the Alkali Acts, and provided for the registration and inspection by officers of the Local Government Board of many chemical factories besides alkali works. The Bill of 1879 gave power to sanitary authorities to take proceedings on their own account if they failed to get their grievances redressed by the action of the Government inspector. This power was omitted, wisely, we think, in the Bill of 1880. In each Bill the factories were divided into three classes, each class being subject to different regulations.

The Bill now before Parliament bears a general resemblance to its predecessors, but differs from them in one or two important particulars. In the first place, it incorporates, and therefore repeals, the Alkali Acts. This is an obvious improvement; one Act is nearly always better than four. Then the chemical works are divided into two, instead of into three, classes. The first of these classes consists of alkali works proper and of those copper works in which hydrochloric acid is evolved. The second class consists of only six kinds of works, the nature of which is described in a schedule. The works enumerated are sulphuric-acid works, cement works, chemical manure works, gas-liquor works (but not tar works), nitric-acid works, and sulphate of ammonia works. Salt works have evidently been omitted by accident from this schedule, for they are referred to specifically in Clause 9 of the Bill. A large number of other works, of which the most important are those of metal, coke, tar, salt-glazing pottery, and glass, are, however, excluded by design, and this emasculation constitutes the gravest fault of the new Bill. All the last-named works are notorious offenders in respect of noxious vapours, and inflict injury upon thousands, and it is impossible to imagine upon what principle of justice they have been struck out of the schedule. Take the tar works, for example. The fumes given out in the distillation of tar are extremely offensive, and even injurious to health, inasmuch as they contain sulphuretted hydrogen. Now, we willingly admit that the larger tar distillers take great precautions to avoid nuisances; but that their success is very limited will be attested by anyone who has the misfortune to live within the radius of their influence. Glass and pottery works are just as bad, and it is a common complaint with the owners of alkali works that their neighbours are allowed to throw into the air with impunity the very gas which the Act of Parliament compels them to condense with the utmost care.

The claim made by the public is certainly not an unreasonable one. The value of these great chemical industries to the country is fully recognised, and the present is certainly not the time when anyone would wish to see our manufacturers handicapped in the great struggle with foreign competition. Some nuisance must be caused by such manufactures, and if it be unavoidable, and not absolutely unendurable, it must be borne like the income-tax and many other annoyances. All that the public asks is that the manufacturers shall, in the words now commonly used in Acts of Parliament, use "the best practicable means" to avoid or abate such nuisances. With regard to acid fumes, good practicable means are well known, and are not costly; and it can hardly be denied that most nuisances might at least be reduced by proper care. Such care, involving nothing ruinous to manufacturers, should surely be enforced by Government.

Up to this point the public, as represented by several large sanitary Associations in the north and south of England, are not really out of harmony with the manufacturers. The evidence taken before the Noxious Vapours Commission proved the fact, often asserted in these pages, that the more influential manufacturers fully recognise their duty to the public, and are only anxious that their difficulties shall be recognised, that they shall be treated fairly, and that, to use the common expression, "they shall all be tarred with the same brush." The case for the manufacturers was ably stated by Mr. E. K. MUSPRATT in a paper read before the Society of Arts on Feb. 25th, 1880, and our own somewhat extensive experience confirms his statements. It is admitted on all sides that factories liable to inflict annoyance or injury on others should be registered, inspected, and subjected to penalties for the infringement of fair rules. At this point, however, agreement ends, for the manufacturers insist most strongly upon certain conditions which the Associations have hitherto been unwilling to concede. The manufacturers profess themselves willing to submit to the visits of properly qualified inspectors armed with the authority of the Central Government, but declare that they will not stand the intermeddling of local authorities, and local officials likely to be biased by local interests, and almost certain to be ignorant. This objection we hold to be a sound one, and the point has been practically conceded in the last as well as in the present Bill.

The other point in dispute is less simple. At the instance of the Associations a clause has been inserted in each of the three Bills allowing "any person" to take proceedings against any one or more of several manufacturers who jointly cause a nuisance. Such a right is already enjoyed as regards injury to property under the Judicature Act, and has already been successfully claimed. In principle the claim is not an unfair one, for when several factories lie close together it is often impossible to detect the offender. But we admit that we think the clause quite out of place in a Bill which on the face of it is merely an extension of the Alkali Acts, or, in other words, a scheme for more comprehensive Government inspection.

Let us try the system of the Alkali Acts first, and, if that fails give more power to sanitary authorities, or private individuals, or both. If the Government are wise they will strike this clause out of the Bill, and try one experiment at a time. The manufacturers will then lose their only fair reason for opposition.

Annotations.

"Ne quid nimis."

ROYAL COLLEGE OF PHYSICIANS.

AT a meeting of the Fellows on the 1st inst., a report from the Council was adopted recommending the annual appointment of two auxiliary examiners in each subject of the examinations for the licence, to be called upon whenever a candidate was liable to be examined by his own teacher. For the rest of the current year the following gentlemen were nominated to act as auxiliary examiners:—Chemistry: Dr. Marcet. Anatomy and Physiology: Dr. Allchin. Medicine: Dr. Ringer. Materia Medica: Dr. Moxon. Midwifery: Dr. Galabin. Surgery: Mr. Holmes. Dr. J. Braxton Hicks was elected councillor in the room of Dr. Greenhow, appointed censor.

ST. THOMAS'S HOME FOR PAYING PATIENTS.

THE St. Thomas's Home is at last announced as being open for the reception of paying patients; and Dr. Walter Edmunds, F.R.C.S., has been appointed as resident medical officer to the institution. It will be remembered that this Home Hospital has been the subject of much controversy in our columns and elsewhere for the last two or three years, and that very various views have been expressed as to the expediency of an attempt to admit well-to-do patients into an institution designed for charitable purposes. On many grounds, any attempt to make such an institution form part of the general system of a public hospital seemed undesirable, especially if the medical staff were to take part in its management, or be called upon to give their services gratuitously. But, as we have often pointed out, there is no such objection to a paying block, organised and nursed under the auspices of the lay authorities of a hospital, if the patients are allowed to select their own medical men; and on the other hand, such an institution may be of great benefit to many sufferers who are above the class of ordinary hospital patients.

It is therefore with no small interest that this experiment, which is in some degree the outgrowth of a germ idea thrown out in our columns, will be watched by ourselves and by the public generally. There is no concealment of the fact that to the authorities of St. Thomas's Hospital the scheme is simply one for making money, and restoring their finances to a more satisfactory condition. This is a legitimate object, if in its pursuance the comfort and well-being of the patients are chiefly kept in view. We are not sanguine of the financial success. We doubt even whether a fair interest will be paid on the initial expenditure. But what is of far more importance to the public and to the profession is that the scheme should have a fair trial, and that the possibility of its general adoption should not be prejudiced by any failure due to imperfect organisation.

So far as the medical and nursing arrangements are concerned, the outlook appears satisfactory. The nursing arrangements are to be under the direct control of the matron of the hospital, and for resident medical officer a gentleman "of the highest medical and surgical qualifications" has been selected. He is to be regarded as the ordinary medical attendant of the patients, who are, however, to be permitted to call in consultation with him any legally qualified medical practitioner. This, we presume, means that the ordinary medical attendant of the patient would, if desired, continue to attend, and the resident medical officer carry out his treatment and instructions in his absence. Only on such an understanding could the scheme be made to work satisfactorily to the profession.

The arrangement of the wards leaves much to be desired As at present planned, two of the ordinary large wards have been fitted up, the one for male the other for female patients. A portion at the entrance of the ward is separated by a wooden partition, and is to be used as a sitting-room. The main body of the ward is occupied in the centre by a passage, and on each side are curtained spaces, each of which forms a separate compartment or chamber. Viewed from above, the arrangement would resemble that of sheep-pens at a fair, the hurdles being replaced by curtains, which do not attain a height of more than six or seven feet. What degree of privacy can be provided by a heavy linen curtain may best be judged by those who have made the trial. Every word spoken, every cry of pain, every cough, or even snore emitted in the ward will be heard by every patient and intensified by the imagination; nor will there be that control on the part of the nurses, or the mutual sympathy and forbearance, which exert so powerful an influence in a general hospital ward. Much tact and discretion will be needed by the medical officer and the nurses to keep matters comfortable if the ward should happen to be full, the male ward being destined for twenty-four, and the female for sixteen patients. Seeing that experience has shown the authorities of the Fitzroy House Home Hospital that even four patients cannot be put in one ward, we fear that there will be serious friction if even twice that number are admitted to each, unless the "silent system" is superadded to solitary confinement.

For the rest, the arrangements of each compartment appear to be well made, although they may not satisfy the most æsthetic tastes. The charge which is to be made, from eight shillings a day upwards, is not exorbitant; indeed, we doubt whether it will be remunerative unless the wards are fairly well filled.

We have made these remarks in no unfriendly spirit, and we trust that our anticipations will prove groundless. What is perfectly clear is that, as at present arranged, the Home will not suit every case—if, indeed, many cases; nor will it serve as a substitute for private hospitals or lodgings. Whilst wishing it success, we cannot but regret that the experiment had not been made on a smaller scale, and under more suitable conditions.

COLLATERAL CIRCULATION.

IT is commonly believed that when an artery is occluded the establishment of a collateral circulation is due to a general increase of blood-pressure dilating the anastomoses of the occluded vessel. The accuracy of this explanation has been carefully investigated by Talma. Experiments on the tongue of the frog, showed that after the occlusion of an artery there is not only no immediate increase, but even a primary diminution, in the rapidity of the current in the collateral branches. In the dog, by means of a tonometer, it can be demonstrated that the pressure in the crural artery is not increased by compression of the carotid or subclavian artery, or both, nor is it lessened when these vessels are opened. Hence Talma concludes that the establishment of a collateral circulation, when an artery is closed, cannot be explained by increase in the general blood-pressure, but is due to dilatation of the vessels produced in some other way. In order to ascertain whether this be due to an influence of the vaso-motor and vaso-dilator nerves, he examined the temperature of the limb before and after section of the nerves which supply the branches of the occluded artery, and also the effect of stimulation of the peripheral extremity of these nerves. The experiments were made upon dogs, and led to the conclusion that after ligature of the crural artery, although dilatation of the vessels of the leg is produced by the influence of the nerves, so that the quantity of blood passing through them is increased, this increase is very slight. He also stimulated the spinal cord after ligature of the crural artery, and came to the conclusion that the dilatation of the vessels was not the result of the action of the vaso-motor nerves. The dilatation of the vessels which could be produced through the vaso-motor nerves was altogether insufficient to explain the complete restoration of the circulation. Since this cannot thus be attributed either to the effect of increased general blood-pressure, or to the action of the vaso-motor nerves, Talma proceeded to investigate the anatomical condition of the collateral vessels, a main branch of which had been tied some time before death. In order to ascertain the dimensions of the vessels he injected them, and compared them with those of a normal leg similarly injected. From such experiments on dogs and rabbits he ascertained that the collateral vessels dilate shortly after the ligature, then those of moderate size, and later still the largest. More careful observations showed that there were rhythmical movements of the vessel between the point ligatured and the first collateral branch above, and that in this part of the vessel a local increase of pressure could be demonstrated, with which a dilatation of the capillaries corresponded. By means of the tonometer he demonstrated that this increase of pressure is purely local, and not general in the arterial system, and that it is proportioned to the size of the occluded branch in relation to that of the main trunk. Hence he arrives at the conclusion that the establishment of a collateral circulation is due purely to mechanical influences—an explanation which differs from that commonly held only in the extent of its application.

THE ACCIDENT TO MR. GLADSTONE.

WE are able this week to give the particulars of the accident—which was certainly serious, and might have been fatal—that happened to the Premier on the night of the 23rd ult. Alighting from his carriage at the garden entrance to his house in Downing-street, and springing quickly on to the stone steps, his foot slipped on a piece of ice; he fell backwards, and striking the back of his head violently against the edge of the kerb cut his scalp, crosswise for two or three inches, to the bone. Otherwise unaffected by the accident, he was immediately on his feet again; and, bleeding profusely from the wound, walked into the house. Dr. Blake, in the absence of Mr. Bond, the usual family attendant, speedily arrived and dressed the wound. Later on it was thought desirable that Mr. Gladstone should be seen by Dr. Andrew Clark, and when this gentleman arrived in the middle of the night he found the illustrious statesman calm, cheerful, and free from the smallest evidence of constitutional disturbance. Next day he was also visited by Sir James Paget, who, with Dr. Andrew Clark, has been since in daily attendance. We further learn that the wound united by "first intention," and that there have been no unfavourable general symptoms of any kind.

LIGHT AND LIFE.

MM. PAUL BERT and REGNARD showed some time ago that the rays of light which are necessary for the growth of vegetables, and especially for the development of chlorophyll, are situated in the red rays, near the line B of the solar spectrum. It has, however, been long known that other rays will suffice to restore the green colour to plants which have been blanched by deprivation of light, although the effect is produced more slowly; and the researches of M. Guillemin have shown that this effect can even be produced by the invisible ultra-red and ultra-violet rays. But there is such a difference between the action of the several rays that it seemed to MM. Bert and Regnard desirable, if possible, to discover the law which regulates their activity. The red rays, which give the maximum effect, have a length of 670 millionths of a millimetre. It was thought *à priori* probable that the other rays, acting in a specially energetic manner, would have a simple relation in length to the red rays, analogous to the relation existing between the wave-lengths of the vibrations of sound which produce the fundamental tones. The octave would be 335, and corresponds to the ray P. But here we are in the ultra-violet region, and the spectrum lessens so rapidly that nothing conclusive could be demonstrated. But the fifth, 450, falls in the region where the dispersion is not excessive—the indigo, between the lines F and G. Barley was allowed to germinate in complete darkess, and when the yellow blades were ten centimetres high, the box was placed two metres from an electric light, from which the light was dispersed by means of a powerful sulphide of carbon prism. In the spectrum thus produced the barley was placed and allowed to grow. The first green tint was visible in the region of the ray B; the third day it appeared between F and G, precisely in the region of the "fifth"; on the fourth day a green tint was perceptible in the red, orange, yellow, blue, indigo, and violet, with two maxima at the points indicated by theory, in the red and the indigo. A second experiment gave quite similar results. The experimenters propose to repeat their observations in regard to other actions of light upon vegetables. In conclusion, they point out that the green region of the spectrum was, on the whole, that in which the barley was least coloured, and there the growth which took place during the exposure was notably less than elsewhere. It thus seems that the green rays have a positively noxious influence.

CO-OPERATION OF HOSPITALS AND PROVIDENT DISPENSARIES.

THERE seems to be a very steady progress of public opinion in favour of really provident dispensaries, and further in favour of their being in organic relation with neighbouring hospitals. From year to year we have given our readers some account of the great movement for providing Manchester and Salford with provident dispensaries. The annual meeting of the Manchester and Salford Provident Dispensaries Branch of the District Provident Society was held on February 24th, under the presidency of Dr. John Watts. The report was a very instructive one, including much information, and may be found in the *Manchester Guardian* of February 25th. Nine branches are now in active co-operation in Manchester and Salford, and a tenth will soon be added. There had been an increase in the membership, and the whole of the six branches first opened were either quite or nearly self-supporting. The total number of ordinary paying members on the books was 9283, members in connexion with the clubs at large works 981, total 10,264; an increase of 828 on the numbers of the previous year. A much larger increase is expected this year. Great care and some money are expended in investigating the circumstances of applicants. The consequence is that in those charities connected with the provident dispensaries there is a much more considerable decrease in the number of persons relieved than in others. In the former there is an average decrease of 38 per cent.; in the latter the decrease is much less. Before the establishment of the provident dispensaries in 1872, the total number of in- and out-patients treated by the free medical charities was 89,442; in 1880 it was 72,837. The various parts of the great problem of provident dispensaries and their relation to hospitals are touched in this report, and have evidently been the subject of much labour and investigation. An attempt was made to alter the rule as regards the wages of those admitted as members from 30*s.* to 40*s.*, but it was unsuccessful. We should still desiderate more information than is given in our contemporary's excellent report on the amount of work done and money received by the medical men.

The *Hampshire Telegraph* contains a full report of a meeting to forward the provident dispensary scheme in connexion with the Royal Porstmouth, Portsea, and Gosport Hospital. The meeting was most harmonious, and showed how good a thing is a little consultation and conference with the medical staff. The dispensaries are to have a separate committee and separate accounts. Four medical officers are appointed as the out-door staff — viz., Messrs. Normal, Rundal, Pike, and Ford. They are to receive any surplus after the expenses are paid, and the payments of members are to be on the scale in use at the Royal Albert Hospital, Devonport, which has a provident dispensary in good cooperation.

TRICHINÆ.

THE meeting of the Académie de Médecine of February 22nd was devoted to the discussion of the viability of trichinæ, and opinions were expressed of a more reassuring character than those to which attention was called last week. M. Colin of Alfort has investigated the extent to which the process of salting renders meat innocuous, and he concluded from a number of experiments that the salting always finally destroys the trichinæ, but that it is impossible to determine the lapse of time necessary, and the danger from such food is greater the shorter the time since the salting. He also investigated the question of what amount of cooking is requisite to ensure destruction. Boiling he found to be effective provided it is maintained for a considerable time, which varies in its necessary length according to the size of the pieces of meat. Roasting only killed the trichinæ when it had been carried beyond the point common for mutton or beef. Quick roasting or boiling, leaving the central parts of the meat red, was quite insufficient. He expressed the opinion that many cases of gastric and intestinal disturbance are the indications of slight trichinisation. M. Davaine, however, mentioned that as low a temperature as 56° C. (134° F.) is sufficient to destroy them, and that in estimating the amount of time needed to cook a joint, thirty to thirty-six minutes should be allowed for each half kilogramme. The same question was considered also by M. Vallin, the results of whose experiments agreed with the statements of M. Davaine. He found that it was necessary that joints of less than six kilogrammes should be cooked for four hours, and that for larger joints boiling for at least five hours was required. The effect of salt in preventing the decolorisation renders the tint, he thinks, an uncertain indication of the sufficiency or insufficiency of the cooking. M. Chatin maintained that salting does not necessarily kill trichinæ. Infested meat was preserved in salt and then given to guinea-pigs, and in several of the animals trichinæ in process of development were found. Moreover, in meat which had been heated to 111° F. the trichinæ were found perfectly mobile.

In spite of the doubt as to the exact temperature at which trichinæ die, and the uncertainty as to the efficacy of ordinary cooking for their destruction, there is a general disposition to rely upon the fact that trichinosis in man is a very rare disease, in spite of the importation of diseased pork. Mr. Mundella lately stated in the House of Commons that our importation is twelve times as great as that of France; and it is reasonable to conclude, therefore, that twelve times as many trichinæ come to us as come to France from America. What is their actual number cannot, of course, be known, but it may be remembered that a single cutlet has been found to contain a hundred thousand worms. The fact that no outbreaks have occurred in this country is probably to be ascribed not only to the influence of cooking, but to the process of salting, which, as just stated, if efficiently performed, seems to kill the parasite. Mr. Mundella intends to wait for an outbreak of trichinosis before following the example of the French Government, and prohibiting the importation of American pork; and the Belgian Government have formed a similar resolution. It would be more satisfactory to know that some measures were taken, by systematic examination of samples of the meat, to ascertain the reality of the danger to this country; for it must not be forgotten that outbreaks and deaths have occurred here in past years.

A ROYAL ACADEMY OF MEDICINE.

IN his address at the annual meeting of the Royal Medical and Chirurgical Society on Tuesday last, the retiring President, Mr. J. E. Erichsen, took occasion to advocate anew a proposition made, discussed, and almost carried into effect more than ten years ago, that the different Societies (representative of the various departments of the profession) meeting in Berners-street should be amalgamated into one body. He pointed out that most of the Fellows of the Medical and Chirurgical Society are members of one or more of the other Societies, and that an amalgamation under one organisation would simplify the working, economise the time and expense, and systematise the labours now distributed between the older Society and the Pathological, Clinical, and Obstetrical Societies. He felt sure that a Royal Academy of Medicine with several sections might thus be securely established, and would be a gain in every way. The reasons which were adduced before against the scheme had, he thought, lost much of their force. This may be so, but it is possible that the same difficulties in adjusting the various claims of the other Societies—all of which have grown with remarkable rapidity since that time—will be even more apparent now than then. Mr. Erichsen will doubtless follow up his suggestion, or at any rate induce the in-coming Council of the Royal Medical and Chirurgical Society to take it up; and knowing what those difficulties were which prevented the amalgamation in the past, a way may be found to satisfactorily carry out the design. The matter is one fairly open for earnest consideration, and if raised again we shall probably hear much of "vested interests" and the like. The project can only be carried out by means of a cordial co-operation and a certain amount of mutual concession on the part of each of the Societies concerned.

DIPHTHERITIC ALBUMINURIA.

THE albuminuria which occurs so constantly in diphtheria was long believed to be a direct effect of the altered blood-state, without any renal lesion. Lancereaux and Brault, however, have described certain organic changes in the kidney. They found the epithelial cells swollen, badly defined, infiltrated with granules of protein, and the lumen of the tubules obliterated in many points by colloid or granular masses. These lesions are analogous to those described by M. Cornil in acute poisoning by cantharidin.

The nature and mode of production of this diphtheritic nephritis is the subject of a recent communication by M. E. Gaucher to the Société de Biologie. It may be *à priori* expected that the lesion would be due to the same mechanism as that which produces the similar changes which have been found in some other infectious diseases. In the nephritis which sometimes occurs in typhoid fever, for instance, there is a similar granular infiltration of the epithelial cells and a similar obstruction of the lumen of the tubules by diffused material or globular masses. These alterations have lately been ascribed by Bouchard to the infiltration of the kidney by bacteria. In a case of malignant diphtheria in which the urine contained a considerable amount of albumen, M. Gaucher, adopting all precautions to prevent the access of external germs, was able to demonstrate without difficulty the presence of bacteria in both the blood and the kidneys. The urine was collected in a glass, washed with alcohol and heated, and, examined immediately, was found to contain a large quantity of spherical or punctiform mobile bacteria (monads or micrococci). There were no rods or chains. In the blood the same organisms were found, less numerous, but perfectly distinct. The patient died seven days after the onset of the disease. The kidneys, examined in the fresh state, were found crammed with bacteria similar to those which had been found in the urine and the blood during life. The epithelial cells of the urinary tubules were filled with highly refracting granules, strikingly similar to the micrococci found in the urine. In sections which had been hardened in osmic acid the same granules were found. From these facts Gaucher concludes that diphtheritic nephritis is of parasitic origin, and that the albuminuria is the result of the passage of the bacteria of the blood through the kidneys. The albuminuria is thus to be regarded as an effort at the elimination of the poison.

OPENING OF MUSEUMS AND PICTURE-GALLERIES ON SUNDAY.

WE are glad to find that the medical profession is well represented in the list of signatures to the address presented to the Premier in favour of opening the British Museum on Sundays. Those who are not compelled to remain in town on Sunday, or who simply obtain such glimpses of the streets as may be gained on the way to or from a place of worship, can have no notion of the melancholy and morally mischievous state of any large city, and particularly London, on the day set apart in every week for rest and religious observances. It is difficult to understand how the youth of the metropolis is preserved from recourse—in sheer dearth of occupation—to the practice of the worst vices. The well-to-do classes, with their comfortable homes, their Sunday *réunions*, or family gatherings, do not participate in the general misery of gloom and inactivity. Some recent inquiries and investigations have led us to take an especially urgent view of this question, and we are convinced it is one which ought to be pressed on the attention of the Government. The argument that a few officials may be inconvenienced to meet the demand cannot weigh for one moment against the crying need of the masses. Let the personal service be made optional; and, if it must be so, let public subscriptions be invited to defray the increased cost. Prejudice must be set aside, and the question discussed on its social merits. It is one of a pressing character, and it relates to a grievance which lies at the root of much demoralisation, and the ruin of many lives.

THE TRANSMISSION OF GLANDERS TO THE DOG.

THE fact that glanders may be communicated to the dog by inoculation, even more certainly than to the rabbit, has long been known, and has lately been confirmed by M. Galtier, who has never met with a refractory subject. Usually, however, the morbid effects remain limited to the points inoculated; the region becomes swollen, and an ulcer forms analogous to the chronic farcy ulceration in the horse. The wound secretes an abundant oily, yellowish pus, which often forms a crust, beneath which the ulceration goes on. As a rule recovery soon follows. Very rarely ulceration occurs elsewhere in the body, and now and then there is evidence of a widespread action of the virus. A dog having been inoculated on the shoulder, and presenting only slight local lesions, the pulp of a lumbar gland was inserted beneath the skin of a donkey, with the result of causing the disease. This seems to show that the poison may be generalised, although the lesions are local; that the virus may be widely spread throughout the system of the dog, and yet cause no general anatomical alterations. It has been said that one attack of glanders in the dog confers immunity against subsequent attacks, but M. Galtier found that two, three, four, five, and even more successive attacks could be induced. After successive inoculations, however, the susceptibility of the animal, originally much less than in the solipeda, lessens, the disease is characterised by lesions less and less marked, and seems ultimately to disappear. Another fact ascertained is that the power of the virus decreases when it has been several times cultivated in the same animal. Donkeys inoculated from a third, fourth, or fifth attack of glanders have had much milder and less acute attacks. They commonly lived three or four weeks after inoculation, and presented more limited lesions than those animals which were inoculated from the horse or from the first attack in the dog.

THE SECTARIAN SPIRIT IN HOSPITAL CHARITY.

SOONER or later the sectarian spirit must be eliminated from hospital charity if we are not to relapse into the religious barbarism of the Middle Ages. Every step forward in the quest for Truth enlarges the view and tends to the discovery that what have been supposed to be the essentials of religion are at best its accessories, and in many cases its shackles. We cannot afford that progress should be hampered by the bonds aud weights imposed by those who have founded churches and charities with limited regards and special purposes. Nowhere are such limitations more intolerable than in relation to the aid human nature impels us to render to the sick. Such restrictions as require that the physicians and surgeons attached to particular hospitals shall be members of the Church of England are antagonistic to the broad principle of humanity, and discredit the form of Religion, in whose name they are imposed. Equally absurd and offensive, not only to good taste, but to common-sense, are requirements like that which appeared in a recent advertisement for a resident secretary for Charing-cross Hospital—namely, that "candidates must be members of the Church of England." It would be well if the logic of facts could be brought to bear on the committees of institutions conducted on the narrow principles indicated by notices of this class. Those who are free from the prejudice they indicate would do well to withhold their subscriptions both to hospitals and Hospital Fund, unless these can be accepted with the stipulation that the charities to which it is intended to contribute shall be administered on the simple grounds of *need*, by agents untrammeled by special affectations of belief or pretences of churchmanship, against which the spirit of manliness revolts.

EXTENSION OF THE HIP-JOINT.

DR. E. H. BRADFORD has recently been experimenting upon the effects of weight extension on the hip-joint in the cadaver. Needles were inserted into the pelvis and into the great trochanter of the femur upon the same side, and "extension was applied in such a way as not to alter the axis of the limb relatively to the plane of the pelvis, and thus disturb the position of the needles." In the body of a child, ten years old, an extending force of 150 lb. was applied without producing any change in the distance between the needles; in another experiment, on an adult male, 100 lb. was employed, but no separation of the needles could be noted, and this not even when all the soft parts over the joint and the capsule had been cut through, and the head of the femur dislocated and replaced. On the other hand, in the body of a full-term fœtus, a weight of a pound was quite sufficient to separate the needles 1 mm. Dr. Bradford states that the fibro-cartilaginous ring attached to the acetabulum grasps the head of the femur so securely that separation of the two bones is quite impossible by extension alone; in the fœtus at term this ring is not fully developed. It must be borne in mind that these observations were all made on healthy joints. It is not difficult to understand that disease of the articulation may cause such a softening and relaxation of the cotyloid ligament that separation of the bones may be readily produced. At any rate, of the efficacy of this plan of treatment intelligently carried out there can be no doubt.

LATTER v. BRADDELL AND WIFE AND ANOTHER.

THIS case, which was tried in the Court of Appeal on Feb. 24th before Lords Justices Bramwell, Baggallay, and Brett, is one which shows the occasional annoyances to which medical practitioners may be subjected from no fault of their own. It appears that Latter was a servant girl in the employ of the Braddells, and that in October, 1879, Mrs. Braddell, suspecting Latter to be pregnant, accused her of it, and, on her denying it, had her subjected to a medical examination by Mr. Sutcliffe, of Knutsford. The girl then brought an action for assault, which was tried at the Assizes before Mr. Justice Denman, but as the jury were unable to agree upon a verdict they were discharged. The case was next tried before Mr. Justice Lindley, who withdrew the case as against the master and mistress from the jury, and as against the surgeon he instructed them that they must be satisfied "that the girl had been overpowered by force, or by threat or terror of actual force." The evidence, however, went to show that the girl never objected to take off her clothes, and that she lay down and was quietly examined. Mr. Murphy urged, on behalf of the plaintiff, that the fact of the girl neither struggling nor forcibly resisting was no more proof of consent than a schoolboy holding out his hand to be struck, but Lord Justice Bramwell upheld the instructions given to the jury by Mr. Justice Lindley, and thought that there had been no evidence that the girl's wish had been overborne by violence or threat. The doctor, his lordship added, had appeared to have acted kindly throughout, but he dropped a word of warning to the effect that in such cases the wish of the master and mistress was no authority in the eye of the law for a doctor to examine a patient against her consent. It appeared to his lordship to have been rather a high-handed proceeding throughout. Judgment for the defendants was accordingly given.

GLYCOGEN IN MUSCLE.

THE relation of glycogen and lactic acid in muscle has been investigated by Böhm. The common method of estimating the amount of glycogen by the prolonged action of heat fails to extract at least 20 per cent., and this can only be obtained by heating the muscle pulp for twelve hours, with water, in a Papin's digester. In a series of investigations the amounts of glycogen extracted by simple heat and by heat under pressure were compared, and it was found that by the latter the amount was from 12 per cent. to 25 per cent. greater than by the former; but even on this method about 5 per cent. of the glycogen is left behind, and hence the procedure is unsuitable for the determination of slight differences in the amount of glycogen.

According to Böhm, the amount of glycogen in muscle does not exceed 1 per cent. of the moist tissue, and its amount is greatest two or three hours after an abundant flesh meal. In fasting animals it does not exceed ½ per cent. In one case, after a full meal, the whole of the glycogen in the muscles of the body was estimated to amount to fifteen grammes, and that in the liver to sixteen grammes. A storage of glycogen thus evidently occurs in the muscles, just as in the liver, and to nearly the same extent. When no food had been taken for thirty-six hours, the amount of glycogen was only ·276 per cent., and three days after the last meal it was only ·036 per cent. Contrary to many statements, Böhm found that the amount of glycogen does not lessen during the first two hours after death, even when the post-mortem rigidity reaches its highest point, which in the animals experimented on—cats—is attained in six to eighteen hours after death, provided the onset of decomposition is prevented by a low temperature. If, for the sake of comparison, one-half of the body is kept in a warm chamber, the amount of glycogen rapidly falls, although it does not completely disappear. From these observations it would seem that the glycogen cannot be the source of the lactic acid which makes its appearance during the post-mortem rigidity. In order to ascertain the relation between the two, the glycogen and lactic acid were estimated in a series of observations, and the result was that the production of lactic acid was not attended by any diminution in the amount of glycogen.

SCIENCE LECTURES.

PROFESSOR STRUTHERS delivered a few days ago a Science Lecture in St. Katharine's Hall, Aberdeen, in which he gave an account of the circulation of the blood and the general balance of the economy. He referred to the practice of bleeding in former times and to its discontinuance as an indication of progress. "We confess," he said, "that the old practice of bloodletting was wrong, and to our brethren of the clinical profession who are wont to be the most severe on us for these changes, we can only reply with that meekness which becomes the confession of error, that unfettered by articles we have moved on and left our errors behind us." Professor Struthers concluded his lectures by showing how many of the facts he had presented to his audience had been obtained by the practice of vivisection, and spoke strongly in regard to the absurdity of those decrying vivisection, who in deer-stalking and grouse-shooting were in the constant habit of wounding sensitive animals, and of leaving them without compunction to die.

A CAUSE OF SUDDEN DEATH IN GANGRENE.

J. PARISE has lately attempted to show that one of the causes of death in cases of extensive moist gangrene is the entrance of putrid gas into the veins, and its rapid passage towards the heart. To support his proposition, he has placed on record two cases of sudden death during gangrene of the leg, in which very shortly after death—an hour and a half and two hours respectively—gas was found in the large venous trunks and in the heart. There is not here any decisive proof that this gas was present before death; but from the great development of gas which is known to take place in the soft tissues in a state of moist gangrene, there is some probability that this is so, and then, if in sufficient quantity, it might in reaching the heart cause sudden death like air drawn into veins during operations close to the heart. Parise maintains that it is thus, and not by any special toxic effect of the gas, whose nature he does not record, that death is produced. He advises that where prompt amputation cannot be performed, the main vein of the limb should be compressed or tied to prevent this absorption of gas, and then later on amputation be performed above the point of pressure. We conceive, however, that there are very serious objections to interfering with the return of blood to the heart in gangrenous limbs, and that this suggestion arises from an exaggeration of the danger of the absorption of the gas at the expense of more general and important pathological conditions.

THE BLOOD IN HIBERNATION.

In the autumn of 1879 Prof. v. Wittich received twelve living German moles (Mus montanus), in order to investigate the amount of glycogen in the liver during their winter sleep. One animal was killed accidentally immediately after its arrival, and the results obtained on a microscopical examination of the blood led to an examination of the blood of the other animals, all killed in perfect health, and in all the same appearances were found. One of the animals had died on the journey without signs of disease, although perhaps in consequence of a bite from another animal.

The blood taken from a vein in the peritoneal cavity contained a large number of thread-like moving objects, which moved the blood-corpuscles lying near them, and, after diluting the blood with a half-per-cent. solution of chloride of sodium, presented an appearance identical with that of the spermatozoa of the frog. These organisms appear to be the same as those described by T. R. Lewis as existing in the blood of healthy rats. They are much larger than the spirillæ met with in the blood in relapsing fever. They were found in the blood from various parts, arterial and venous, in every animal. They disappear from the blood as soon as the decomposition sets in and the putrefaction-bacteria appear. They were very numerous, ten or twelve being found in every drop of blood, and they furnish a new proof of how large a number of parasitic organisms may exist in the blood without causing any disturbance to the general health. Attempts were made to inoculate guinea-pigs, but in every instance with a negative result.

THE INVESTIGATION INTO THE WORKING OF THE MEDICAL ACTS.

It may now be considered settled that we shall have an inquiry by a Royal Commission into the working of the Medical Acts. Mr. Mundella says the determination to proceed by a Royal Commission has been arrived at after consultation with members of the House who served on the late Select Committee. If this Commission is so appointed as to consist of competent persons it will justify itself.

CASE OF NEPHRECTOMY.

On Feb. 22nd Mr. Morrant Baker performed the operation of nephrectomy on a child in the Evelina Hospital. Several weeks previously Mr. Baker had cut down upon the right kidney from the loin, and had found it to be sacculated and suppurating. As free drainage failed to relieve the symptoms, the organ was excised from within the capsule through the nephrotomy wound. We are informed that the child is "doing remarkably well, the temperature for the last day or two ranging from 100° to 98°, takes nourishment well, and is picking up strength." This operation has not yet established itself as a recognised surgical procedure, and it is most important that all the cases in which it is attempted should be fully recorded.

THE CAUSE OF DEATH IN INQUEST CASES.

Many coroners habitually disregard the enactment of the Birth and Death Registration Act of 1874, which specifies the "cause of death" as one of the particulars to be ascertained and certified for insertion in the death register in inquest cases. This detracts much from the value of the mortality statistics prepared and issued from time to time by the Registrar-General. The Registrar-General, in his last weekly return, calls especial attention to a recent inquest in Hackney, which was held upon a child aged three years, the verdict in which case was "Sudden, suppressed eruption." Well may the Registrar-General deplore the vagueness of such a verdict, which is useless for the purposes of public health or mortality statistics. There are good grounds for believing that this case was one of suppressed small-pox, but if this were the case the record of fatal small-pox cases in London last week is made deficient. As inquests are held in more than 5 per cent. of the total deaths in England and Wales at an average cost of about £3 each, it is manifestly important that the verdicts should throw some light upon the true cause of death.

A case of some importance, as bearing on the use of morphia as a local application in skin diseases, formed the subject of a coroner's inquiry at the London Hospital on the 28th ult. The report from which we quote (*The Times*, March 1st) does not state the nature of the skin affection, which occurred in a woman fifty years of age. Lead lotion was at first prescribed, but owing to the irritation this was changed for a lotion containing liq. morphiæ hydrochloratis. It appeared that the prescription was misread by the dispenser, the word "liq." being written in the wrong column and overlooked by him, and the strength of the solution was, therefore, made half as much again (as regards the morphia) as intended. The mistake was most unfortunate, for the patient succumbed with symptoms of narcotic poisoning, and her death seems to have been attributable to the morphia. It would be obviously unfair to offer any criticism on the facts as here presented; but the case should inculcate the caution necessary to be observed in prescribing powerful toxics to the diseased skin.

The *Manawatu Times* records the death, on Christmas Eve, of Dr. Walker, surgeon to the Constabulary Forces stationed at Taupu, at the age of thirty-six. The deceased gentleman had obtained the New Zealand Cross for distinguished bravery in the field during the last native war. A local newspaper, at the time the decoration was awarded, testified of Dr. Walker that times out of number he had "carried men out of the thick of various frays when the bullets were as plentiful as hailstones; on one occasion he was carrying a wounded man on his back to a place of safety, when he (the wounded man) was shot dead whilst being so transported."

Edmonton still continues to furnish illustrations of the practices of builders in the metropolitan suburbs. Five summonses against a builder were recently heard before the magistrates of this district for having used improper lime, bricks, and timber in the erection of certain houses. Fines and costs were imposed to the amount of £75 11*s.* 6*d.* Would that the example of the Edmonton local authority were more largely followed by the local authorities of the metropolitan suburbs.

A coach-builder of Lyons has just completed forty ambulance-waggons, which are to be sent to Athens at an early date. These are constructed after an improved model, and are destined to follow the army over the roughest and most difficult country. They are very light, and have only two wheels. Each waggon contains four beds, which are suspended in a manner calculated to lessen, as far as possible, the shaking incidental to the road.

We are informed that the Royal College of Physicians and the Royal College of Surgeons of London contemplate making a grant of fifty guineas towards the expenses of the International Medical Congress, to be held in August next. The other medical corporations are considering whether they will not follow this example.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Barnsley (*Rural*).—Dr. Michael Thos. Sadler's report for 1880 is one of exceptional interest. In addition to information on the sanitary state of the district for the particular year to which it refers, it gives a brief summary of the work which has been done in the district since it was formed seven years ago. This account is peculiarly gratifying, and shows what may be effected by a judicious officer of health under circumstances of industries and populations having many and peculiar difficulties, to which, we fear, medical officers of health have too frequently yielded. When Dr. Sadler began his duties he had to contend with centres of population which had grown without any regulation whatever from pure rural villages into crowded colliery towns, without drains and sewers, insufficiently supplied with water, and this not always pure, and with no arrangements for the proper disposal of filth of any sort, liquid or solid. The populations were, in fact, living in a most deplorable state amidst their own accumulated filth, and the result was seen in an average rate of mortality of nearly 27·0 per 1000 inhabitants throughout the district, and in some parts a death-rate of 40·0 per 1000. "Since then, by patience and perseverance, by repeated statement of pressing needs, by not asking for too much at a time, but bringing forward first the most urgent wants, and those the necessity for which could be most clearly proved, a great improvement has been brought about." No less than 13,881 yards (nearly eight miles) of main sewerage have been constructed, exclusive of a large amount of drainage work done by private owners; several parts of the district have now an excellent water-supply; and a system of public scavenging has been introduced into sundry townships. By-laws respecting new buildings have also been adopted, and under them not less than 667 houses have been erected, which it may be assumed will, at least, be free from the structural evils which too commonly characterised the older houses. There is still much to be done in the district, but Dr. Sadler shows that by pursuing the same course he has hitherto done improvements of the sort already accomplished are still being steadily prosecuted in the parts of the district that need them; and a death-rate of 23·3 in 1880, as compared with the death-rate of 27·0 seven years ago, may be taken as evidence of the benefit the district has already obtained from the change effected in its sanitary state.

Kettering (*Urban*).—Mr. J. Winter Dryland's report for this sanitary district for 1880 is particularly interesting from its giving an account of the sanitary improvements which have been made in Kettering during the past eight years. Eight years ago this town, although occupying an admirable natural situation, was without proper drainage, had numerous filthy open privies and ashpits, its soil was sodden with leakage from such apologies for drains as existed, and from its foul middensteads, and a large number of the wells from which it derived drinking water were polluted. As a consequence of this state of things every summer and autumn brought its long list of cases of diarrhœa and typhoid fever with many deaths; and whenever small-pox, scarlet fever, or measles appeared, they spread rapidly, and the cases were usually of a malignant type. Now, Kettering has an excellent system of drainage, the sewers are fairly well ventilated and periodically flushed, and the sewage is almost completely purified before being cast into the brook into which it is ultimately passed. The town has the luxury of a constant supply of pure water from a deep well. A thorough system for the removal of ashes and dirt has been organised, and is well carried out by the servants of the Local Board. The greater number of privies have been converted into waterclosets. Where sink-pipes have been found in connexion with drains they have been disconnected. A hospital for infectious diseases has, moreover, been provided. Accompanying these changes fever and diarrhœa have diminished. No death from typhoid fever was recorded in the town in either of the years 1877, 1878, and 1879, and only nine deaths from diarrhœa occurred in 1880. Other zymotic diseases have also diminished. Kettering has reason to congratulate itself on the intelligent action of its sanitary authority and officers.

Mile-end Old Town (*Metropolis*).—Dr. Corner estimates the population of this district for the purpose of his report at 110,000, and he gives the birth-rate for 1879–80 at 38·5 per 1000 inhabitants, and the death-rate at 22·96, that of the metropolis generally for the year being 23·25. He has little eventful to relate in his proceedings during the year. Scarlet fever was the one exceptionally fatal disease, but although Dr. Corner holds it to be "the most intractable infection with which we have to combat," he thinks that "even its subtle destructive power can be successfully defeated by judicious management and sanitation."

Hastings (*Urban*). — Mr. Ashenden in his summary for 1880 gives the death-rate for that year as 18·16, the population being estimated at 40,400. The infantile mortality is reported to be "still very high," and is assigned, "unquestionably," to "the increasing use of artificial foods." The use of the sanatorium appears to be becoming more and more appreciated, and a combination of the urban sanitary authority with the rural sanitary authority for erecting a more capacious building is suggested.

East Dereham (*Urban*).—Mr. Henry Bird Vincent reports a death-rate of 16·4 per 1000 inhabitants during 1880 among a population estimated to number 5790. Two things specially attract attention in his report—namely, his comments upon the futility of his action in dealing with scarlet fever, and his expression of a hope that presently his sanitary authority will put a scheme of scavenging (and that not an expensive one) in operation in his district.

Axbridge (*Rural*).—Dr. De Courcy Lyons reports a death-rate of 13·3 per 1000 inhabitants during the last nine months of 1880. He refers to cases of diphtheria in one part of the district, apparently in connexion with the use of very filthy pond-water for drinking.

Longton (*Urban*).—Mr. James Weaver, reporting to the Town Council, and tendering his resignation on account of ill health as medical officer of health, observed:—"I have been your medical officer for ten years, and the first year (1871) I took office the death-rate of the borough averaged 41 per 1000, and the rate for the first three years (1871, 1872, and 1873) averaged 31·3. The average death-rate for the last three years (1878, 1879, and 1880) was 24·2, and the rate for 1880 is 22·9 per thousand. These figures show a saving, at the lowest calculation, of 150 lives a year, and I think your officials may fairly congratulate themselves on the result of their ten years' work; and to save so many lives each year is, I consider, a grand reward to the authorities of the borough for the money and labour which have been expended on its sanitary arrangements."

Peterborough (*Urban*).—Mr. Sinclair Thomson estimates the population of the city at 25,000, and gives the death-rate for 1880 at 20·3 per 1000 of the inhabitants. Last year appears to have been exceptional from the little prevalence of zymotic diseases in the city. But it is obvious there are several things to be done in Peterborough before it will enjoy the full degree of health its population ought to have. Although the municipal water-supply is excellent, there are still many wells in use, of which the water is impure. Moreover, from certain illustrations of the occurrence of typhoid fever given by Mr. Thomson, it would appear that the privies and ashpits of the city are not always constructed or regulated as they should be.

Greenock.—Dr. Wallace reports that the mortality of the town, during the four weeks ending Jan. 29th, was at the rate of 25·0 per 1000 of the population annually. Among the cases of infectious diseases ascertained during this period by the sanitary department to exist in the town, 107 in number, there were twelve cases of typhus. The number of these cases removed to the local authority's hospital was twenty-one, including the whole of the typhus patients. The greater proportion of cases of typhus were traced to pre-existing instances of the disease.

Holbeach.—Mr. R. R. Harper reports for this town during 1880 a death-rate of 12·9 per 1000 inhabitants. Although he regards this rate of mortality as very satisfactory, he is by no means content with the sanitary conditions under which the population lives, and particularly complains of the bad state of privies and ashpits and the faultiness of the water-supply.

St. Marylebone.—Mr. Wynter Blyth has some interesting observations in his report for St. Marylebone for the month ending the 9th February on the probable effect of the interruption of domestic-refuse cleansing and of due flushing of drains and waterclosets, in his district, during the memorable frost and snow-storm in January. The "dust-carts" had to be taken away from their work to free the great thoroughfares, and the frost sealed for several days numerous water-pipes. Mr. Blyth gives some instructive advice as to dealing with the infection of foot-and-mouth disease now existing among the metropolitan cattle-sheds.

VACCINATION IN LEEDS.

The vaccination officer for Leeds, Mr. Thos. Holmes, has presented to the Board of Guardians his report for the half-year ending June 30th, 1880, and a supplementary report for the year 1879. These reports, as previous ones by the same officer, show what can be done when the vaccination officer does his duty thoroughly, has his heart in his work, and is efficiently supported by an intelligent Board which is loyal to the vaccination law. The reports make clear the remarkable fact that the proportion of children vaccinated in Leeds is 3·14 larger than in the whole of England and Wales. The Local Government Board, in its last annual report, observed of vaccination in Leeds, "that it showed with what completeness a system of vaccination may be carried out by efficient administration." By the present reports it is evident that the efficiency is kept up. No death from small-pox has been registered in Leeds since July, 1877, and one case of the disease only occurred then. While the number of children born from year to year who are unaccounted for in vaccination is now reduced almost to a vanishing point in Leeds, over 9000 young children are unaccounted for annually in London. Mr. Holmes says of his present reports, they "give the largest numbers that I have yet been able to present as vaccinated; and clearly show that the general disposition of the inhabitants is to obey the law and secure for their offspring the safeguard against small-pox afforded by vaccination."

THE MONSALL FEVER HOSPITAL.

A conference has been held at the Royal Infirmary, Manchester, between the Committee of the Monsall Fever Hospital and the representatives of various local authorities and boards of guardians on the financial state of the hospital. A proposition has been made to the boards of guardians who use the hospital to raise their weekly payment per case, and a committee has been formed, consisting of representatives of the local authorities (eleven in number) and of the Manchester Health Committee, for further conference with the committee of the hospital, on the 17th inst.

Mr. Dodson has been questioned in the House upon the vaccination of very young infants in workhouses. It would appear that the mothers leave the workhouse not unfrequently as early as one fortnight after their confinement, and that as a rule children born in the workhouse pass into the outer world unvaccinated, and probably remain so. As, however, these children are as liable to small-pox as any other unvaccinated children, efforts are being successfully made to secure their vaccination before going out of the workhouse. There is no medical objection to this early vaccination, but the susceptibilities of certain persons who object to vaccination altogether are offended thereby.

The Guildford Rural Sanitary Authority having been called upon to provide proper outlet sewerage for the Charterhouse School at Godalming, and having refused to do so, has, after local inquiry, been declared by the Local Government Board in default under the 299th section of the Public Health Act, 1875, and ordered to provide the necessary sewerage. The Sanitary Authority has, however, refused to obey, and determined to submit the case to the opinion of counsel.

The report of Messrs. Crookes, Odling, and Meymott Tidy, to the Local Government Board, on the composition and quality of daily samples of the (filtered) water supplied to London from Jan. 20th to Feb. 19th, 1881, shows that although many of the samples examined were more or less turbid from finely suspended clay and sand, the water was, nevertheless, wholesome, of good quantity, and well oxygenated.

A person has recovered from his landlord, in the Greenwich County Court, £40 rent (paid in advance), and £10 expenses of removal for having let to him a house which proved most unwholesomely damp.

A correspondent using the signature "Medicus" write to the public journals complaining that the public vaccinato of his district refused to revaccinate a daughter of his cook aged ten and a half years. It is difficult to believe that an qualified medical man can be so grossly ignorant of th practice and law of vaccination as to have written this letter

At the Leicester Borough Police Court last week, twenty seven anti-vaccinationists were summoned for non-complianc with the Compulsory Vaccination Acts. Conscientiou objections were urged in most cases, but the Bench inflicte in each case a fine of 10*s*., including costs, or seven days imprisonment.

The Uxbridge magistrates have dismissed the summon taken out by the Thames Conservators against the Uxbridg Local Board for allowing the sewage of their district to flow into the Thames, the Bench regarding the evidence of th fact as insufficient. A case for a superior court was granted

Of fourteen deaths from small-pox among children unde five years of age reported by the Registrar-General last week eight of the sufferers were known to have been unvaccinated and there was no evidence as to the vaccination of five others

Mr. Roland P. Blennerhasset, M.P., believes, apparently that "cleanliness, ventilation, &c." would be sufficiently protective against small-pox. If other persons were no concerned, it is a pity he cannot be left in this belief.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality continues to decline, and is now very considerably below its average for the season. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5400 births and 3195 deaths were registered last week. The births exceeded by 214, whereas the deaths were 62 below, the average weekly numbers during 1880. The deaths showed a further decline of 72 from recent weekly numbers; and the annual death-rate, which had decreased from 31·0 to 22·4 in the four preceding weeks further fell to 21·9 last week. The lowest death-rates in the twenty towns last week were 16·7 in Sheffield, 18·5 in Bristol, 18·7 in Portsmouth, and 19·0 in Leicester. The rates in the other towns ranged upwards to 24·1 in Newcastle-upon-Tyne, 25·9 in Manchester, 26·6 in Oldham, and 28·6 in Liverpool. During the past eight weeks of the current quarter the death-rate in the twenty towns averaged 25·0 per 1000, against 26·0, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had steadily declined from 390 to 315 in the five preceding weeks, did not exceed 290 last week; these included 76 from whooping-cough, 56 from scarlet fever, 45 from small-pox, and only 25 from fever, principally enteric. The annual death-rate from these principal zymotic diseases averaged only 2·0 per 1000 in the twenty towns, and ranged from 0·3 and 0·4 in Hull and Sunderland, to 2·7 and 3·1 in Leeds and Norwich. Scarlet fever showed the largest proportional fatality in Oldham, Portsmouth, and Leicester. The 13 deaths from diphtheria in the twenty towns included 8 in London and 2 in Birmingham. The death-rate from fever in the twenty towns was unusually low. Small-pox caused 49 more deaths in London and its outer ring of suburban districts, and one in Brighton, but not one in any of the eighteen other large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased in the seventeen preceding weeks from 77 to 704, further rose to 752 on Saturday last, a higher number than has been under treatment in these hospitals since the spring of 1878. The number of new cases of small-pox admitted to these hospitals, which had been 176 and 183 in the two previous weeks, further rose to 187 last week. The Highgate Small-pox Hospital contained 49 patients on Saturday last, against 46 and 53 at the end of the two preceding weeks.

The deaths referred to diseases of the respiratory organs in London, which had steadily declined from 702 to 364 in the four previous weeks, were 367 last week, and 100 below the corrected average number in the corresponding week of the last ten years; 252 resulted from bronchitis, and 71 from pneumonia. The annual death-rate from lung diseases (excluding phthisis) was equal to 5·2 per 1000 in London; the rate from the same diseases was 8·7 in Liverpool.

The causes of 94, or 2·9 per cent., of the deaths in the twenty towns last week were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths was 1·8 per cent. in London, while it averaged 4·0 per cent. in the nineteen provincial towns. No uncertified deaths were registered last week in Portsmouth or Norwich, while their proportion was largest in Wolverhampton, Bradford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate averaged 22·5 per 1000 last week, against rates declining steadily from 34·7 to 23·9 in the four preceding weeks; this rate was, however, 0·6 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 16·5 and 21·1 in Greenock and Edinburgh, to 25·4 and 25·7 in Paisley and Aberdeen. The deaths referred to the seven principal zymotic diseases in the eight towns, which had steadily declined from 125 to 87 in the four previous weeks, further fell to 70 last week, and were equal to an annual rate of 2·8 per 1000, which was, however, 0·8 above the average rate from the same diseases in the twenty English towns. The zymotic death-rate in the eight Scotch towns ranged last week from 1·3 and 1·9 in Greenock and Perth, to 3·3 and 4·3 in Edinburgh and Leith. The 70 deaths from zymotic diseases included 17 from whooping-cough, 14 from diarrhœa, 14 from fever, 13 from diphtheria, 7 from scarlet fever, 5 from measles, and not one from small-pox. The 17 deaths from whooping-cough showed a further decline from recent weekly numbers, and included 8 in Glasgow and 3 in Dundee. The fatal cases of scarlet fever also showed a further decline, and 4 of the 7 were returned in Edinburgh. The deaths referred to fever, which had been 8 and 10 in the two previous weeks, further rose to 14 last week, and included 6 in Glasgow, 3 in Edinburgh, 2 in Leith, and 2 in Greenock; the annual death-rate from fever in the eight towns averaged 0·55 per 1000 last week, and was more than three times as high as in the twenty English towns. The fatal cases of diarrhœa were less numerous than in the previous week. The 13 deaths referred to diphtheria also showed a decline, and included 6 in Glasgow and 4 in Edinburgh. Four of the 5 fatal cases of measles occurred in Glasgow. The deaths referred to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy), which had declined from 348 to 193 in the four preceding weeks, further fell to 150 last week, and were equal to an annual rate of 5·9 per 1000; the death-rate from the same diseases in London did not exceed 4·7 per 1000. The largest excess in the fatality of lung diseases in the Scotch towns occurred last week in Paisley and Perth.

HEALTH OF DUBLIN.

The rate of mortality in Dublin continues to show a marked excess compared with that prevailing in most of the large English and Scotch towns. The annual death-rate from all causes in the city, which had declined from 47·4 to 38·5 in the four preceding weeks, was equal to 38·1 last week. During the past eight weeks of the current quarter the death-rate in the city has averaged no less than 40·6 per 1000, against 24·5 in London and 23·0 in Edinburgh. The 245 deaths in Dublin last week were within one of the number in the previous week, and included 24, or nearly 10 per cent., which were referred to the principal zymotic diseases, against 22 and 31 in the two previous weeks. These 24 zymotic diseases included 10 from fever (typhus, enteric or typhoid, and simple continued), 4 from scarlet fever, 4 from whooping-cough, 3 from diarrhœa, and one each from small-pox, measles, and diphtheria. The annual death-rate from these zymotic diseases was equal to 3·8 per 1000 in Dublin last week, while it did not exceed 2·3 in London, and was 3·3 in Edinburgh. The deaths referred to fever, which had been 7 and 17 in the two preceding weeks, were 10 last week, and equal to an annual death-rate more than nine times as high as the average rate from the same cause last week in the twenty large English towns. The fatal cases of scarlet fever in Dublin showed a slight increase last week, while those of whooping-cough were less numerous. The deaths both of infants and of elderly persons exceeded the numbers returned in the previous week.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

SALFORD INFECTIOUS DISEASES HOSPITAL.

There are few more important subjects connected with practical sanitation than the hospital treatment of infectious diseases in large towns. Dr. Tatham, in his valuable report on the sanitary condition of Salford in 1879, unfortunately only just issued, gives some valuable information bearing upon the work done during that year in the Wilton Hospital for Infectious Diseases belonging to the borough of Salford. This hospital now contains 70 beds for the isolation and treatment of infectious diseases, and we are told that the Town Council have decided not only to enlarge it by the erection of an administration department, but to secure its more complete isolation by the demolition of some neighbouring houses, and also to add at least twenty to the number of beds available for patients. We often hear as an argument against the erection of such hospitals that the prejudice against their use on the part of those for whom they are intended is so great as almost to defeat the object in view. At any rate this is not the case in Salford. It appears that between the opening of the hospital during 1876 and the end of 1878 no less than 868 cases were admitted, and that 307 cases were admitted during 1879. Thus the prejudice against hospital treatment in Salford, if it existed, seems in a fair way to be overcome. The 307 cases of admission during 1879 included two of small-pox, four of typhus, thirty-one of enteric fever, 157 of scarlet fever, sixty-two of measles, and one of diphtheria. The total cost of maintenance in the hospital during 1879 was little less than £3000, and was equal to 21*s.* 6*d.* per week for each inmate, including the officers of the institution; and as the average duration of each patient's residence in hospital was thirty-six days, it may be calculated that the average cost of each patient for maintenance was about £5. The number of completed cases recorded in 1879 was 313, of which 236 were recoveries and 77 deaths; thus the rate of mortality was equal to 24·6 per cent. of the completed cases, and exceeded the average proportion in such hospitals. The rate of mortality was equal to 16·6 per cent. among 42 cases of enteric fever; 25·6 per cent. among 156 cases of scarlet fever; and 21·3 per cent. among 61 cases of measles. With regard to enteric fever, the rate of mortality among 443 completed cases in the Metropolitan Asylum Hospitals during 1879 was 18·6 per cent., showing a difference of 2 per cent. in favour of the Salford Hospital. The fatality among the 1317 cases of scarlet fever treated at the Metropolitan Asylum Hospitals during 1879 showed a mortality not exceeding 16·2 per cent., against the high rate of 25·6 in the Salford Hospital. This excessive fatality of scarlet fever in Wilton Hospital may, in part, be due to the disease assuming a more virulent type in Salford than in London. The subject, however, is worth inquiry. The mortality among cases of measles is also undoubtedly great, and we hope that Dr. Tatham, in his next report, will give some further information on this point, which may show that the rates during 1879 were exceptionally high. Such variations may always be expected in dealing with small numbers.

MANCHESTER AND SALFORD SANITARY ASSOCIATION.

The annual report of the Committee of the Manchester and Salford Association for 1880, while showing that the Association is continuing its useful work, does not, unfortunately, show any tendency to resiliency in its funds. During the last few years the income of the Association has been gradually diminishing, owing to death and removal of former members and other causes, and now it is compelled to appeal to the public for pecuniary help if it is to continue its usefulness. Let us hope that the next annual report will show good results from the appeal. The sanitary inspection department has not been so successful as was anticipated.

HEALTH OF CALCUTTA.

Dr. M'Leod's report for the last quarter of 1880 on the health of Calcutta shows no very striking departure from the usual meteorology of the period; food plentiful and cheap, but a considerable mortality from disease generally. The mortality from fevers was below the average; that from cholera above. The autumnal cholera exceeded in amount the spring cholera, "a very unusual circumstance." Wherever any tendency to grouping of the disease was observed, a special inquiry was made, and in all such instances the grouping was found around very filthy tanks. The arrangements for carrying out the new vaccination laws have been completed.

PLAGUE IN MESOPOTAMIA.

Information has reached the general press by a roundabout route through Russia that plague has broken out at Djaffar in Mesopotamia. Four deaths from the disease are reported.

It is hardly necessary to state that the announcement in an evening paper of the existence in Dublin at the present time of over 150 cases of typhus fever, from which disease "no less than seven doctors have died," is very far from being accurate. The only death in the ranks of our profession, of which we have received information, is the lamented one of Dr. Peele, a short obituary notice of whom will be found in our present issue.

Small-pox and scarlet fever are stated to be prevalent in Rio de Janeiro, and the outbreak of yellow fever has not yet subsided. Guayaguil is now reported to be free from the latter disease.

THE SERVICES.

THE AFGHAN HONOURS.

The *Gazette* of Tuesday, conferring honours and rewards on the officers who served in the late Afghan war, contains the names of four medical officers on whom Her Majesty has bestowed the distinction of Companion of the Bath. Deputy Surgeon-Generals Annesley Charles Castriot De Renzy, Stephen Chapman Townsend, of the Bengal Army; Deputy Surgeon-General Henry Bolton Hassard, and Brigade Surgeon James Arthur Hanbury, of the British Medical Service.

THE TRANSVAAL WAR.

A number of medical officers are under orders for South Africa to reinforce the medical staff in the Transvaal. Surgeon Coats embarked at Kingstown, on the 27th ult., in the transport *Calabria*, in medical charge of the 7th Hussars; Surgeon Woods, proceeding in charge of the left wing of the 7th Hussars, in the transport *Nemesis*. Brigade Surgeon Corbett, Surgeon-Major Joseph Watts, and Surgeon H. Scott have also embarked for Durban. Two officers of the Army Hospital Corps, with a detachment of thirty-five non-commissioned officers and men, are detailed for service, and will sail in a transport next week. Surgeon-Major Frederick B. Scott, M.D., has been appointed to the staff of Sir Frederick Roberts, G.C.B.

We deeply regret to announce the death, from wounds received in the recent action at Majuba Hill, of Surgeon-Major Cornish, A.M.D. He was the son of a much respected member of the profession, Dr. Cornish, of Taunton. We regret to learn that Surgeon Arthur J. Landon, A.M.D., is also amongst the list of officers killed in the battle near Lang's Nek, on Saturday last.

On Tuesday Sir Frederick Roberts called on Sir William Muir, Director-General of the Army Medical Department, in reference to the supply of further surgical appliances for use in the field, the authorities being in possession of information which leads them to believe that an extra supply is necessary. As a result a consignment of medical instruments and drugs will be sent in the *Balmoral*.

THE INDIAN MEDICAL SERVICE.

The new pension rules for the Indian Medical Service have, we understand, been approved by the Secretary of State for India, and will be promulgated very shortly. They will take effect from the 1st January, 1881, so that officers who are now retiring will benefit by the new terms, which will be liberal and comprehensive. Under the provisions of the Warrant of November 16th last for the Indian Medical Service twenty-one brigade-surgeons will be appointed in the Bengal Presidency—fourteen in Madras, and nine in Bombay. These promotions are to be made by selection from the list of surgeons-major on full pay. Their commissions will be antedated to 27th November, 1879, so as to harmonise with the British Service.

Lord Hartington has informed Mr. Cowan, M.P., as President of the Indian Medical Defence Fund, that a despatch has been received from the Government of India with reference to the recent changes in the Indian Medical Service, and is now under the consideration of the Secretary of State in Council. The correspondence will be shortly presented to Parliament.

CONVALESCENT DEPÔTS, INDIA.

Surgeon-Major Curtiss Martin is appointed to the Medical Charge of the Landour Depôt; Surgeon-Major J. Fergusson to the Medical Charge of the Darjeeling Depôt; Surgeon-Major Robert Lewer to the Medical Charge of the Murree Depôt.

The undermentioned Medical Officers are attached for duty at the Convalescent depôts as under for the ensuing hot season: Surgeon J. F. Williamson, Nynee Tal; Surgeon-Major C. E. Smith, M.D., Landour; Surgeon A. W. Browne, Kasauli; Surgeon J. Boulger, Dalhousie; Surgeon-Major J. H. Moore, Murree.

Surgeon-Major J. H. Robothom and Surgeon H. A. Fogarty have been granted six months' leave from India on private affairs. Surgeon-Major J. H. Loch, Bengal Medical Service, has been granted furlough to Europe for fifteen months.

Surgeons-Major T. Butler Power O'Brien and Decimus F. de Hodgson sailed for Bengal in H.M. troopship *Malabar*, which left Portsmouth on the 4th inst.

Brigade-Surgeon S. A. Lithgow has been granted six months' leave from India on private affairs.

Surgeon-Major Edmond Townsend, M.D., Army Medical Department, is under orders to proceed to the West Coast of Africa for service on the Gold Coast in connexion with the threatened Ashantee war. Surgeons J. J. Lamprey and N. Cameron, M.D., have proceeded from Sierra Leone with the 1st West India Regiment to Cape Coast Castle for the expedition against the King of Ashantee.

ARMY MEDICAL DEPARTMENT.—Surgeon-General Henry Kendall, M.D., has been granted retired pay; Surgeon-Major Thomas Moriarty, M.D., who has been granted retired pay, to have the honorary rank of Brigade Surgeon; Surgeon-Major Samuel Flood retires on temporary half-pay.

BOMBAY MEDICAL ESTABLISHMENT.—To be Surgeon-Major: Surgeon John Robb, M.D.

ADMIRALTY.—The following appointments have been made:—Surgeon G. W. F. Armstrong, M.D., to the *Malabar*, vice Clarke; Surgeon Robert M'Ivoer to the *Monarch*, vice Bell.

INTERNATIONAL MEDICAL CONGRESS (1881).

PREPARATIONS for the approaching International Medical Congress are being vigorously pushed forward by the Executive Committee, and the arrangements are now beginning to take a more definite form. The inaugural address by Sir James Paget, the President-elect of the Congress, will be given in St. James's Great Hall, which has been already engaged for the purpose, on Wednesday morning, Aug. 3rd. The following mornings will be devoted to the business of the various Sections; while the afternoons (with the exception of Saturday afternoon, which will be left free for garden parties, excursions, &c.) will be occupied by the general meetings of the Congress, at which four addresses will be given by distinguished men of four nationalities. Three gentlemen have already promised to give these addresses: Professor Huxley, probably on "The Connexion of General Science and Medicine"; Professor Volkmann, of Halle, on "Modern Surgery"; and Dr. Billings, of Washington, on "Medical Literature." The fourth address, to be given by a distinguished Frenchman, has not as yet been finally arranged. The meetings of the various sections will be held in rooms at Burlington House, courteously placed at the disposal of the Committee by the University of London, the various learned societies, and the Royal Academy of Arts. This, however, not providing the required amount of accommodation, the Committee have engaged Willis's Rooms for the occasion, and four of the sections will hold their meetings there. As stated in an earlier notice, no less than 40,000 individual medical men in various parts of the world received the original circular of invitation during August and September of last year, and since then the secretaries of the various sections have been actively engaged in circulating provisional lists of subjects which seemed in the opinion of the Committees of the sections those best suited for discussion and papers. Numerous replies have been received in answer to these communications, in some cases leading to alterations in the subjects selected. These amended programmes have again been distributed among those most likely to take interest in them, and are now combined into a pamphlet, and are issued together with the rules of the Congress printed in the three official languages to any medical man making application for them to the Secretary General.

Since the list of names published in November last, a large number of our foreign colleagues have definitely announced that they will come to the meeting, and there seems every prospect of the attendance from abroad being a full one. Meanwhile, depending on the number of names appearing as officially connected with the Congress, and on the subscription list, together with the number of gentlemen from abroad who have positively stated their intention to attend, a certain estimate of one thousand members may be made; and it seems not unreasonable to assume that at least double that number will attend.

The Reception Committee are busily engaged, and have decided upon giving an evening reception at South Kensington, and perhaps a second in the Albert Hall, but at present the state of the subscription list does not warrant them in making the arrangements definitive. The Lord Mayor purposes entertaining members of the Congress at dinner at the Mansion House on August 4th.

H. H. CLUTTON, R. P. SMITH, } Auditors.
T. D. ACLAND, W. H. BATTLE, } Hon. Secs.
Feb. 24th, 1881.

The balance has been handed over to the Treasurers of the London Murchison Memorial Fund for the purpose of aiding in the formation of a Scholarship in Clinical Medicine.

GLASGOW ROYAL INFIRMARY.

THE annual meeting of qualified contributors and subscribers to this institution was held on January 31st. The report then submitted showed that 5117 patients had been admitted into the hospital during the year, being 195 less than in the previous year. The mortality in the medical wards was 12·7 per cent., in the surgical wards 6·4 per cent. The total mortality of patients treated to a conclusion was 9·3 per cent., or deducting 147 deaths which occurred within forty-eight hours after admission, 6·6 per cent. The number of patients treated in the dispensary was 21,232; of these, 10,515 were medical and 10,715 surgical. The treasurer reported that the total revenue, ordinary and extraordinary, amounted to £28,294 10*s.* 11*d.*; the total expenditure, ordinary and extraordinary, to £32,365 2*s.* 8*d.* The deficit of £4070 11*s.* 9*d.* was met by drawing on the capital account. The explanation given as to the increased expenditure of recent years is of considerable interest, as it shows the progress made in the management of such institutions as the Royal Infirmary, and the more enlightened views which are beginning to prevail among managers and directors. It is stated, in the first place, that the whole nursing system, and the domestic arrangements generally, have been greatly improved. In 1861, when the accommodation supplied by the hospital was greatly increased by the opening of the new Surgical House, the number of nurses was 44, their wages were from 15*s.* to 17*s.* 6*d.* per month; they were inadequately fed; no regular meal, not even dinner, being provided for them; their food consisted chiefly of such articles as herrings, eggs, chops, cheese, &c., which they cooked in their respective wards, and they did all the scrubbing, cleaning, and washing connected with the wards. Now the number of nurses on regular duty in the same number of wards (31) is 62; these are divided into two classes, day and night nurses. One of each class is appropriated to each ward, and her services are reserved exclusively for the physician or surgeon of the ward to which she belongs. There are also 29 probationer-nurses, who may be called the floating staff; one of these is placed as an assistant in each ward. There are 20 scrubbers and cleaners constantly employed, and 16 washerwomen and laundry-maids. The probationer's wages is £12 a year; after she is qualified she receives £20, which increases at the rate of £2 a year till it reaches £30. Thus the amount paid as wages to nurses and other officials has risen since 1862 from £2648 to £6000. The expenditure on medicines and medical and surgical appliances has also increased from £810 to £2580. Provisions have risen in price, and the diet scale has been improved all round. The results of this liberal policy have been very satisfactory. A better class of women have come forward as nurses, and a most marked improvement has taken place in the general tone of the institution. The death-rate has also fallen in a remarkable degree. In the five years from 1861 onwards the average annual deaths were 623; in the last five years they averaged 478; in the last four years only 468. Much money has been spent in adding to the accommodation of resident assistants, nurses, and others connected with the establishment. There still remain to be provided additional and better sleeping apartments for the nurses, and plans are now under consideration for an extensive range of dispensary buildings to be erected at the back of the hospital. In these new buildings ample space is provided for the medical school associated with the dispensary. The managers concluded by stating that the expenditure, though undoubtedly great, contrasted favourably with that of other similar institutions, and that it could not, with due regard to efficiency, be reduced.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Friday, further petitions for redress in connexion with the East India Army Medical Department were presented from Messrs. J. Anderson and A. S. Reed. On the motion of Mr. Woodall, the Blind and Deaf Mute Children Bill was read a second time. The second reading of the Coroners (Ireland) Bill, which is "blocked" by a notice of opposition from Mr. Warton, was further deferred for a week.

Scotch Medical Qualifications.

On Monday Sir Trevor Lawrence asked the Vice-President of the Council if he was aware that the highest qualification of the Royal College of Surgeons, Edinburgh—viz., the Fellowship—is to be had without examination, and even *in absentiâ*, by persons holding lower qualifications, on payment and by a process of vote by ballot; if he was aware that the highest qualification of the other two Scottish medical corporations—viz., the Royal College of Physicians, Edinburgh, and the Faculty of Physicians and Surgeons, Glasgow—is given on similar terms; and if he could inform the House whether such a system has ever been the subject of representation or remonstrance by the General Medical Council.—Mr. Mundella: I have reason to believe that, with regard to the Royal College of Surgeons of Edinburgh, a Fellowship can be obtained by persons who are already members of the Colleges of Surgeons in England, Scotland, or Ireland, upon the terms stated; but I understand that Fellowship is not a licence or qualification for practice, but is a distinction conferred by the College by a three-fourths vote. With regard to the Faculty of Physicians and Surgeons of Glasgow and the Royal College of Physicians, Edinburgh, I have not yet been able to obtain certain information. With respect to the question of so-called higher titles, I understand it was discussed by the

Medical Council in 1859, and it was then decided that in the opinion of the Council in future no licence or degree should be given by any of these bodies without examination; and in the year 1870 the subject was again brought forward in reference to Clause 16 of the Medical Act Amendment Bill, but in consequence of the withdrawal of the Bill and pending further legislation, the subject has not been at present renewed. The question of these higher titles will form part of the inquiry into the working of the Medical Acts which the Government propose to shortly institute. A petition for inquiry into the East India Army Medical Department was presented from Alexander Campbell.

Medical Reform.

On Tuesday, in reply to Mr. Errington, Mr. Mundella stated that the Government had arrived at the conclusion that they should best attain a satisfactory investigation of the subject of medical reform by referring it to a Royal Commission.

Workhouse Vaccination.

Mr. Hopwood asked the President of the Local Government Board whether it was true that a practice of vaccinating infants as early as the first week after birth, "and even earlier," (!) has been adopted in some workhouses. If it was done under the sanction of the Local Government Board; and was the free consent of the mother in these cases first obtained. Mr. Dodson said it was quite true that the practice of vaccinating children in the first week after birth had been adopted in some workhouses, and in some individual cases the operation had been performed even earlier than the completion of the first week. But, in the circular recently issued by the Local Government Board, it had been pointed out that it was desirable that children should be vaccinated when six days old in order that the result might be ascertained before the thirteenth day—that was, before the mothers left the workhouse, which was often at a very early period. If the vaccination of children born in workhouses was not performed before they left they would probably not be vaccinated at all, and thus add to the large number of children in the metropolis who escaped vaccination altogether. No complaint had reached him with regard to the result of these operations. He was asked if the free consent of the mother was in all cases at first obtained. In many cases the free consent of the mother to the vaccination of the children had been specially obtained; in other cases where it had not been asked for, acquiescence, in the absence of objection, had been assumed. (Mr. Hopwood: "Oh!") He was not aware of any instance where a child had been vaccinated after the refusal of the mother.

Revaccination.

Mr. Firth asked the President of the Local Government Board whether he was aware that, owing to the increase of small-pox in Western London, many inhabitants were being revaccinated; and whether, having regard to the fact that no lymph can be obtained from secondary vaccination and that great difficulty exists in obtaining lymph, he was prepared forthwith to provide a proper supply of calf vaccine or humanised lymph for all duly qualified persons applying for the same. Mr. Dodson replied that there could be no doubt that owing to the prevalence of small-pox in the west of London many persons were being revaccinated. Although no doubt it was very desirable that everyone should be revaccinated, it would have been much better in many cases that, instead of waiting for this epidemic, they had been revaccinated as the Board had recommended. With regard to the supply of lymph, it must be borne in mind that the National Vaccination Establishment was intended to supply lymph to registered practitioners, not to individuals, and he was not aware of any case in which a registered practitioner had applied for lymph and had failed to obtain it. With regard to the last portion of the question, he might state that arrangements were in progress for providing a supply of calf vaccine, but considerable difficulty would be experienced in organising the necessary establishment. He could only hope that the arrangements would shortly be made.

Trichinosis.

Mr. Dixon-Hartland asked the Vice-President of the Council whether he had been informed of the prevalence of trichinosis amongst swine at Chicago, and was aware that large quantities of pork, ham, bacon, &c., are exported from that city to this country. Whether he was further aware that the French and other Governments have, in consequence, prohibited the importation of pork from the United States. And whether, in view of the deadly character of the disease propagated by the consumption of diseased meat, two deaths having been reported from Dublin within the last few days, he had taken any, and, if so, what steps to ascertain if any infested meat had been imported into the United Kingdom; and if not, what steps he was prepared to take to prevent such importation. Mr. Mundella said the Privy Council had no evidence of the prevalence of trichinosis in swine at Chicago. That place was merely the centre to which hogs were sent to be cured from the surrounding districts before being sent to this and other countries. He understood the disease could not be detected in the living animal, and generally only by microscopical examination of the flesh. He was aware that the importation of American pork had been prohibited in France, but the importation in that country was only one-twelfth of the import to this country. Italy, France, Portugal, and Spain prohibited the import two years ago, but those countries were self-sustaining countries, and not dependent, as we are, on foreign supplies. It was only right to say that no facts had been brought to his knowledge to justify any alarm on the subject. With respect to the prevalence of disease in dead animals, the Local Government Board were responsible. The Privy Council only dealt with disease in living animals, but he must say that the prohibition of such an enormous food-supply would only be justified by the most urgent necessity. With regard to the deaths in Dublin, there was no evidence to show that the deceased died from trichinosis, or that they had been in the habit of eating American pork.

A petition was presented from Falkirk for inquiry into the subject of medical relief in Scotland. Lord F. Cavendish, in reply to Captain Maxwell Heron, stated that the Government proposed to insert in the estimate an increased grant in aid of the medical relief in Scotland. The return recently ordered, on the motion of Mr. A. O'Connor, of examinations in London for the naval medical service, was presented. Colonel Alexander was discharged from further attendance on the Select Committee on the Contagious Diseases Acts; and Colonel Tottenham was added to the committee in his place. Sir Herbert Maxwell fixed the 29th inst. for the discussion on spurious American compounds, sold as butter, upon which he will move the following resolution:—"That it is desirable that such steps shall be taken by the Legislature as will ensure, as far as possible, that such of these compounds as are harmless shall only be sold under distinctive names, and that the importation and sale of those which are hurtful or dangerous to health be prohibited altogether." Mr. Dixon-Hartland gave notice that on an early day he will call attention to the danger of trichinosis arising from the importation of American pork, and move a resolution.

Fulham Small-pox Hospital.

Mr. Firth gave notice of the following questions for Thursday:—To ask the President of the Local Government Board, whether it is the fact that Fulham Small-pox Hospital is now made the receptacle for more than one-third of the small-pox patients of the whole of London; whether the borough of Chelsea, which includes the whole of Kensington, Notting-hill, Fulham, Chelsea, and Hammersmith, have volunteered to take charge of their own small-pox patients; whether the Metropolitan Asylums Board and the Local Government Board have not declined to confine the said hospital to such district; whether the Local Government Board do not decline to receive a deputation to urge such limitation; whether, according to the decision in a recent case, a small-pox hospital is not a nuisance *per se*, which may at any time be stayed by injunction; whether he is aware that the inhabitants of Western London, in consequence of such refusal as aforesaid, propose to take legal proceedings to obtain such injunction; and whether, in order to save public money being wasted in fruitless legislation by the Metropolitan Asylums Board in defending such proceedings, he is prepared forthwith to advise such Board to close Fulham Small-pox hospital, and to remit the patients to the care of local authorities, or otherwise to abate uch nuisance.

On Thursday, in answer to Mr. Firth, Mr. Dodson said, the notice of the hon. member contains no less than seven questions. I will endeavour to answer them as concisely as I can. My answer to the first question is, that it is not a fact that Fulham Small-pox Hospital is made a receptacle for more than one-third of the small-pox cases in the metropolis. The total number of patients in the hospitals is 763, of whom 217 are in Fulham. The answer to the second is, that I have not received any offer from the borough of Chelsea to take charge of their own small-pox patients. The borough has no power to undertake any such charge, and the vestries of the several parishes in the borough have not provided any hospital for such cases, although express power was given them to do so as far back as 1866, and they have from time to time been reminded of it. The answer to the third question is, that the hospitals of the Metropolitan Asylums Board, of which Fulham is one, were provided for the whole metropolis, at the cost of the ratepayers generally, and so long as there are space and accommodation admission will not be refused to patients coming from any part of that area. In answer to No. 4, I have to say that the answer to No. 3 will afford a reason why it is useless to receive a deputation on the subject. As to whether, according to the decision in a recent case, a small-pox hospital is not a nuisance *per se*, which may at any time be stayed by injunction, I have to say that it is now the subject of appeal in the House of Lords. I am not aware that the inhabitants of West London propose to apply for an injunction; and in reply to the last question I have to state that I am not prepared to advise the Metropolitan Asylums Board to close its hospitals, and to remit the small-pox patients generally to the care of the local authorities, especially seeing that the Vestries and District Boards have as a rule failed to provide asylums as they should have done—at all events for non-pauper cases, who form more than one-half of the cases.

"Audi alteram partem."

ANEURISM TREATED BY THE USE OF THE CATGUT LIGATURE.

To the Editor of THE LANCET.

SIR,—The results of the cases whose history was read at the Medico-Chirurgical Society on Feb. 8th are so important that I think some review of them is necessary in the interests of surgery. The President said that the condition of artery revealed by post-mortem examination was unknown to him, and other speakers, myself among the number, proffered similar opinions. My remarks, however, indicated that I intended to devote further study to the subject, having at the time a suspicion, awaiting investigation, as to the reason of the non-closure in the lumina of the vessels.

This suspicion was awakened by the absence of clot, above or below the ligature, in either Mr. Adams's or Mr. MacCarthy's case. In studying the subject it is to be observed that although there were but two patients, yet there are three cases—(1) the right carotid, tied by Mr. Adams; (2) the right subclavian of the same patient, tied by Mr. Treves; (3) the left subclavian, tied by Mr. MacCarthy. In Mr. Treves's deligation considerable suppuration took place; and the vessel is the only one of the three which exhibited perfect closure, the operator attributing the difference between the result of his operation and of the previous one by Mr. Adams to the inflammation and thickening which took place around the artery which he had tied. The wound over the carotid (Mr. Adams') had not inflamed.

There is, however, another factor. So many vessels have now been tied successfully while asepticism has been maintained that we can hardly go back upon that improvement and consider it a detriment. We must think of other matters, and more especially the singular absence of clot. Now, if the carotid artery tied by Mr. Adams, or the left subclavian tied by Mr. MacCarthy, had really been closed by the ligature (even though none of the tunics were divided), and if those vessels had remained occluded, as clinically appeared, in the one case for thirty-six days, and in the other for forty-one days, clot would have formed above and below the ligature, and would in that time have become so adherent that no restoration of passage could have been possible.

The condition must then, I think, be otherwise explained. Mr. Adams tied the carotid thus: "A stout catgut ligature was used and tied in a double, and then a single hitch." Mr. MacCarthy kindly answered a question I addressed to him by letter thus: "The ligature was tied with a double hitch, and then a single one, only differing from the ordinary knot by the doubling of the first hitch." Therefore, out of the three cases the only one which was tied by a single hitch repeated was Mr. Treves's operation on the right subclavian, and it was the only one which succeeded in occluding the artery.

If a piece of prepared catgut be drawn through the fingers, it will rarely be found to be smooth, but to be roughened by little asperities studded over the surface. These are not sufficient to obstruct in a knot made with single hitch. As soon as I came home from the meeting specified, I tied, with double hitch, a number of knots round different arteries, and I found that these roughnesses sufficed in the intensified friction thus produced to render the tightening of the first knot difficult and even uncertain. In one or two instances the sense to my hand was that of having tied the experimental object tightly, the loop being afterwards found evidently lax.

This, however, is only the hypothetical explanation; the fact remains that two out of the three cases were tied with the double hitch, and in those two occlusion either did not take place or was very transitory.

I am, Sir, your obedient servant,
RICHARD BARWELL, F.R.C.S.,
Senior Surgeon and Lecturer on Surgery,
Charing-cross Hospital.
George-street, Hanover-square, Feb. 15th, 1881.

To the Editor of THE LANCET.

SIR,—That an artery may be temporarily occluded by the use of the catgut ligature, and may then again become pervious, is the main point demonstrated by Messrs. Treves and MacCarthy's cases brought before the Royal Medical and Chirurgical Society on Feb. 8th. The inference, however, as to the bearing of this fact upon the treatment of aneurism should be, I venture to think, somewhat different from that drawn by the writers of the papers alluded to, and by the speakers on those papers. To them the temporary nature of the occlusion (even though in Mr. Treves's case the period of occlusion was eighteen days) seemed an argument of overwhelming force against the use of the catgut ligature in such cases. To them it seemed an essential point in the treatment of aneurism by the ligature that the artery ligatured should be obliterated. But is this so in all cases? Does not Mr. Treves's case present an instance in the opposite direction? The aneurism for which the ligatures were used was cured, though the carotid afterwards became pervious. Still I am willing to allow that in cases of distal ligature we should aim at the absolute obliteration of the artery ligatured. It is, however, an open question whether in the cases requiring proximal ligatures the temporary nature of the occlusion is a fatal objection. That aneurism can be successfully dealt with by temporary obstruction of the channel of the artery on its proximal side has been proved by the many recorded cases of cure of aneurism by digital or mechanical pressure, kept up perhaps for six, eight, ten, or twelve hours. Why, then, should not *ligature-pressure* be as effectual? Have we not in the catgut ligature a means of employing temporary pressure, with as little risk to the patient, as by digital or mechanical pressure? If we could always ensure primary union of the wound by employing antiseptic dressings there is no doubt that the answer would be in the affirmative. Nevertheless, the increased probability of our getting primary union when the catgut ligature and antiseptic dressing are used makes this method a very much safer one than that of the hitherto orthodox plans. So that when digital or mechanical pressure cannot be used or has failed, we have the comparatively safe method of *ligature-pressure* to fall back upon. And in the term *ligature-pressure* I would include the plan of passing a catgut ligature round the artery without necessarily cutting through its two inner coats; the object being simply to bring together the inner surfaces of its channel and to retain them for a certain number of days in such apposition. I adopted this method successfully in a case of femoral aneurism—*ligature-pressure* by means of a catgut ligature was employed around the external iliac artery. Though the wound did not heal by the first intention there was no accident following the operation, and the aneurism was completely cured. I am, Sir, yours obediently,

Henrietta-street, Feb. 15th, 1881. W. SPENCER WATSON.

THE CHLOROTIC MURMUR.

To the Editor of THE LANCET.

SIR,—Dr. Bramwell has asserted in the most categorical manner that "Naunyn, George Balfour, and others *deny* that the inorganic murmurs of chlorosis are *ever* arterial." It turns out that Naunyn has written nothing whatever on the subject; while the ultimately arterial character of the chlorotic murmur follows as a necessary corollary, from the dependence, as I suppose, of the primary murmur upon ventricular dilatation, and has been distinctly described by myself in your own journal, little more than three years ago, as occurring in the later stages of chlorosis. In these circumstances it seems to me that a simple apology for his carelessness would be more consistent with Dr. Bramwell's position than an attempt to defend himself by showing that others are also to blame. It is surely not too much to expect of a teacher of medicine and a writer on the "Diagnosis of Cardiac Murmurs," that he should at least know so much of the literature of the subject as will prevent him misrepresenting the views which he criticises.

Dr. Bramwell has also quoted at some length the opinions of Rosenstein, Sibson, and Hayden in support of the idea that reduplication of the second sound is produced by irregular contraction of the two ventricles, the left getting into diastole before the systole of the right is finished. It is difficult, however, to see how this theory can explain that "combination of double second sound with valvular inadequacy at the aortic orifice," which, according to Hayden, is not an infrequent occurrence. Neither is it easy to understand how a satisfactory solution could be found for any one of the many physiological and physical difficulties which are opposed to this view. It is quite needless to enter upon them now, because modern physiology has supplied us with an explanation of this phenomenon, which each one can investigate for himself, and which is not only sufficient but also consistent with both physics and facts. Ceradini has experimentally taught us that during a ventricular systole the segments of the arterial valves are not flapped back on the walls of the artery, but float within the blood current. They are maintained in equilibrium on the one hand by the axial stream escaping from the ventricle; and on the other by reflex currents originating at the exterior of this axial stream, which flow outwards and downwards against the arterial wall, from which they are reflected upon the posterior surfaces of the semilunar segments. Ceradini has also taught us that the moment the blood pressure within the artery equalises that within the ventricle, the semilunar segments of the arterial valve, no longer kept in equilibrium by opposing currents, fall together and close the arterial orifice. This systolic closure of the valves, as he terms it, is accompanied by an audible snap that initiates the second sound, which is only strengthened, but not produced, by any of the events accompanying the cardiac diastole. When the intra-arterial blood pressure is so great that it equalises that within the ventricle before the systole of the latter is finished, then we have the systolic closure of the valves and its audible snap, separated by an appreciable interval from the diastolic snap (of the arterial systole), and thus we have a reduplicated second sound. The primary systolic snap occurs only in that artery the blood pressure within which is in excess—in mitral regurgitation this is, of course, the pulmonary artery,—while the diastolic snap is simultaneous in both. Thus we have reduplication of the second coming and going, with variations of the intra-arterial blood pressure, without any interference with the action of the heart, the systole and diastole of both ventricles continuing to be both regular and synchronous, any residual blood not sent into the artery finding its way backwards to the auricle. And we have also a perfectly efficient explanation of the concomitance of a reduplicated second, with free aortic regurgitation. It is only when we wander amidst a maze of opinions that we find the facts of cardiac pathology difficult to explain; so soon as we deal with them according to the laws of physics and in the light of experimental physiology, the obscurity disappears. I am, Sir, yours obediently,

Edinburgh, Feb 25th, 1881. GEORGE W. BALFOUR.

"OVARIAN DYSMENORRHŒA, WITH RETROFLEXION OF THE UTERUS."

To the Editor of THE LANCET.

SIR,—I am glad that a remark in a letter of mine, which you were so good as to publish, has elicited from Dr. Wynn Williams the statement that he does not know the termination of many of the cases which he has treated with his intra-uterine stem.

It is well known that many deaths have occurred after the use of intra-uterine stems, and I am not alone in having met with or heard of many cases in which prolonged illness followed the application of such instruments. (I refer in this statement to intra-uterine stems generally, and not to Dr. Wynn Williams's stem in particular; on the contrary, I regard that with which his name is associated as one of the least dangerous.) Remembering these cases, it has been with astonishment that I have heard Dr. Wynn Williams say that he has *never* seen any ill consequences from the use of his stem. This startling statement is now, I am glad to find, explained. Dr. Wynn Williams has not seen any bad results, because he has not inquired as to the subsequent course of all his cases. Is it not possible that some of those whom he has not followed up may have left off coming to him because they were too ill to do so?

Anteflexion is very often found without any symptoms, and symptoms associated with anteflexion do not necessarily depend upon it, and may often get well without alteration in the shape of the uterus. Therefore it is to be expected that any kind of treatment applied to a large number of cases of anteflexion associated with symptoms would, if not immediately fatal, occasionally be followed by apparent improvement.

The publication of isolated cases proves nothing, either as to the safety of the remedy, or its efficiency in removing symptoms. It is necessary that *every case* should be recorded, and not merely those who came back to thank their medical adviser for the good done to them.

I am, Sir, faithfully yours,
G. ERNEST HERMAN.

West-street, Finsbury-circus, E.C., Feb. 1881.

NOTE ON THE DIAGNOSIS OF CAVITY IN THE LUNG.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 18th, 1880, Mr. S. C. Smith of Halifax described a physical phenomenon which he had observed in two cases of cavity of the lung—namely, a sound, synchronous with the cardiac systole, which could be heard over the trachea, so loud in tone that it could be distinctly perceived at a distance of some inches from the patient.

In Mr. Smith's opinion this sound is "obviously produced by the impact of the contracting ventricle against a neighbouring cavity, expelling such a puff of air as to produce a sound in the bronchus and trachea."

Permit me to draw Mr. Smith's attention to the fact that the same physical sign has been observed and described by Professor Gerhardt of Würzburg, in whose "Lehrbuch der Auscultation und Percussion," third edition, p. 270, I find a passage of which the following is a translation:—"Very rarely one can hear over cavities, as in one case described by Cejka, and in another by myself, a systolic whistling murmur of high pitch. I could show at the post-mortem examination of the latter case that a dilated branch of the pulmonary artery which ran through the cavity probably gave rise to this bruit. Cavities situated near the heart often give rise to râles or to musical and metallic sounds synchronous with the heart's systole. Remarkable are the few recorded cases (I have personally had occasion to observe one instance) in which râles *synchronous with the heart's systole became so much louder in consequence of 'resonance,' that they were audible at a distance of several feet.*"

This extract from Gerhardt's "Lehrbuch" probably contains the correct explanation of the above-mentioned phenomenon, which is otherwise difficult to account for. In THE LANCET of Jan. 8th, Dr. Drummond of Newcastle has already pointed out that Mr. Smith's explanation is untenable, for the reason "that systolic contraction of the ventricle means a diminution in the bulk of the heart." I think that the theory of increased resonance, the cavity itself acting as the resonator, also explains the cessation of the sound during inspiration which took place in Mr. Smith's cases, when the patient was breathing deeply or quickly; inasmuch as, under these circumstances, the conditions favourable to resonance may cease to exist.

I have recently had occasion to observe a similar symptom in a young lady suffering from the third stage of phthisis. Signs of cavity existed in the left apex, and another cavity could distinctly be made out in the right infra-clavicular region, giving a tympanitic sound on percussion, which changed its pitch according as the patient assumed either the recumbent or the erect posture; the sound was also modified by the opening and closing of the mouth. On auscultation, amphoric breathing, with large bubbling râles, could be heard, and at the same time a *systolic bruit*, which was present during inspiration and expiration, and was also distinctly audible over the trachea.

Bearing in mind what I saw personally at the very post-mortem above referred to by Gerhardt, I at once diagnosed in the case before me the presence of a dilated branch of the pulmonary artery, which had not as yet become impervious, lying across the cavity.

The patient died of profuse hæmoptysis in a few days; and although a post-mortem examination was not permitted, I think there can be no reasonable doubt of the correctness of my diagnosis, having regard to the peculiar termination of the case. Your obedient servant,

SIEGMUND MORITZ, M.D.,
Assistant Medical Officer to the Manchester Royal Infirmary.

Manchester, Jan. 31st, 1881.

"A SLANDER REFUTED."

To the Editor of THE LANCET.

SIR,—Under this title the *Philadelphia Medical Bulletin* publishes in its January number a letter from Dr. S. D. Gross, in which he asserts that a statement made by me in your journal "is false in every particular."

The absence of clinical clerks and dressers in the Pennsylvania Hospital, Philadelphia, led me to make inquiries of the doctor who most courteously showed me round. His reply so surprised me that before leaving the hospital I asked the question again, to be sure that I was not mistaken. "I was assured" by this gentleman "that at Jefferson College, which is one of the leading medical schools in the country, *a man might take his degree in medicine without ever having seen a case.*"

I am surprised that Dr. Gross should call my statement false, and then endorse it himself. In the last paragraph of his letter he makes the supposition that I have taken a degree at Jefferson College "without ever having seen a case," and in proof that I am not a solitary or exceptional instance, he adds, "precious pearls are daily thrown before *such* swine in the ample amphitheatres of the Philadelphia hospitals."

If I or any other man can obtain the degree of M.D. at Jefferson College, Philadelphia, "without ever having seen a case," I think I may justly remark that "clinical study is apparently unnecessary," and in so doing make no reflection on "the standard of clinical teaching in Philadelphia hospitals." I am, Sir, your obedient servant,

London, Feb. 23rd, 1881. A. E. BROSTER, M.R.C.S. Eng.

IRELAND.

(*From our own Correspondent.*)

THE Bazaar recently held in the Ulster Hall, for the benefit of the Belfast Royal Hospital, has realised the handsome sum of £1073 12*s.* 11*d.* The collections held on Hospital Sunday for the same institution amounted to £530 10*s.* 11*d.*, which, although somewhat in advance of that obtained the previous year, yet must be regarded as a sum totally unworthy of a wealthy town like Belfast. This hospital recently received a donation of 100 guineas from Mrs. Lyons of London, "as a token of gratitude for kindness shown to her son." It appears that the young gentleman in question happened to be in Belfast amongst strangers, and was admitted to the Royal Hospital, in which he died, after ten days' illness, from typhoid fever. The concert held last week for the benefit of the Belfast Hospital for Diseases of the Skin realised £35 2*s.* 7*d.*

At the Cork Fever Hospital last year there was an increase of 284 patients under treatment, as compared with 1879. This increase accounted for the additional expenditure, which the committee of the hospital hope will be materially reduced by the next corporation grant. The mortality from typhus fever was equal to 14 per cent., and, excluding seven cases admitted in a moribund condition, an actual mortality of 11 per cent. was obtained, a result which compares very favourably with the returns from other institutions of a similar kind.

A case of successful ligature of the right subclavian and right common carotid arteries simultaneously, for aneurism of the arch of the aorta, under the care of Dr. J. Mansergh Palmer, surgeon to the Armagh County Infirmary, deserves record. The patient, a woman aged fifty, was admitted to hospital on Feb. 10th, 1880, having noticed a slight swelling close to the right sterno-clavicular articulation during the previous November. On the night of the 12th Dr. Palmer found her suffering from great difficulty of breathing, stridulous respiration, lividity of face and neck, coldness of extremities, and other symptoms which rendered an immediate operation absolutely necessary. She was removed to the operation room, the right common carotid artery was tied, and as the tumour did not appear to decrease and pulsation continued, the subclavian was also ligatured. On the 29th the carotid ligature came away, and on March 2nd the subclavian. On April 27th she left the hospital, both wounds being quite healed. Early in June she caught cold and was readmitted to the Infirmary, but refused to take any medicine. On June 14th hæmorrhage took place from the old cicatrix in the neck over the carotid vessel, being complicated with hæmoptysis, which also occurred on the following day, and on the 10th there was profuse hæmoptysis, and death supervened 125 days after the operation. A post-mortem examination showed that the aneurism involved not only the arteria innominata, but also the arch of the aorta, while at the posterior and left side of the arteria innominata was an opening communicating with the left vena innominata, which latter communicated with the trachea at one point and at another opened into the right lung.

A Local Government Board inquiry was held at Bangor last Saturday in reference to a petition from the Bangor Town Commissioners, as the urban sanitary authority, to be allowed to construct waterworks for supplying the town and district with water, and also for a proper sewerage scheme. The commissioners have applied for a loan of £14,000 to carry out the necessary works. At the inquiry Dr. Bolton, medical officer of health, and others, gave evidence as to the great necessity which existed for a water-supply, not only for domestic purposes, but for flushing the sewers when formed.

Dr. Alexander Duke, recently assistant-physician at the Rotundo Lying-in Hospital, has been presented by the students of that institution with a handsome timepiece, bearing a suitable inscription, and also a valuable gold locket from the nurses belonging to the hospital.

At a recent meeting of the students of the Catholic University Medical School it was resolved to appoint a committee to receive subscriptions from past and present students of the School towards the erection of a memorial to the memory of the late Dr. Cryan, who for twenty-seven years discharged the duties of Professor of Anatomy and Physiology in the Medical School.

A man named Creagh died from hydrophobia in the Tipperary Infirmary last week, having been bitten by a mad greyhound so far back as July, 1880.

At a coroner's inquest held last week in Dublin the following rider was appended to the verdict by the jury:—"We are of opinion that the Bill now introduced into Parliament, providing remuneration for coroners and giving them power to appoint deputy coroners, should be entertained by the Government, and we feel the metropolitan county coroners are inadequately paid, and should be provided with a deputy."

THE Duke of Connaught has consented to preside at the anniversary festival of the Hospital for Sick Children, Great Ormond-street, to be held at Willis's Rooms on Wednesday, March 16th.

Obituary.

EDWARD PEELE, M.K.Q.C.P.I., L.R.C.S.I.

IT is with great regret we record the untimely death of Mr. Edward Peele, of Dublin, which sad event took place on the 18th inst., from that scourge of the profession, typhus fever, after two weeks' illness, aged forty-three. The deceased was connected with one of the city dispensaries, and it was in the discharge of his professional duties that he contracted the disease from which he died. Educated for the musical profession, he afterwards turned his attention to medicine; and in 1872 obtained the licence in medicine of the College of Physicians, and the following year the diploma in surgery of the Royal College of Surgeons in Ireland. He was one of the medical staff of the Hospital for Diseases of the Throat, Physician to the Hospital for Incurables, a Demonstrator of Anatomy in the Royal College of Surgeons' Medical School, and Visiting Physician to the Coombe Lying-in Hospital. Mr. Peele was one who made many friends, and in private life his kind and genial disposition, with musical abilities of a very high order, combined to make him a general favourite. His remains were interred last Monday in Mount Jerome Cemetery, being accompanied to their last resting-place by a large number of his professional brethren and of the citizens of Dublin.

The Committee of Council of the Irish Medical Association, at a meeting held on Feb. 22nd, passed the following resolutions:—"That the Council of the Irish Medical Association have learned, with the deepest regret, of the untimely death of Dr. Edward Peele, a member of the Council, and they desire thus to record their sense of the loss sustained by the Association in the removal of one so loved and trusted." Resolved further—"That the Hon. Secretary to Council be requested to convey to the relatives of the deceased an expression of the sympathy felt with them in their bereavement by the members of the Council." The Committee of Council, after passing these resolutions, adjourned as a mark of respect to the memory of Dr. Peele.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Licentiates of the College on March 1st:—

Griffiths, Herbert Tyrrell, Devonshire-place.
Holberton, Henry Nelson, Hampton, Middlesex.
James, Herbert Ellison Rhodes, Livermere Rectory, Bury St. Edmunds.
James, James Thomas, Llwnjack, Llandovery.
Jay, Melville Richard Hindmarsh, Fentiman-road.
Mathews, Sidney Robert Harvey, Bickley.
Milne, James Kershaw, Royal Infirmary, Manchester.
Mouritz, Arthur Albert, Richmond-street.
Nance, Henry Chester, St. Bartholomew's Hospital.
Shelswell, Oscar Berridge, Trinity-square.
Sutton, Samuel Walter, Richmond-terrace.
Thistle, Frederick Thomas, Vincent-terrace.
Thomas, John, Ystalyfera, Swansea.

BRITISH MEDICAL SERVICE.—The following is a list of candidates for appointments as Surgeons who were successful at the competitive examination in London on Feb. 14th:—

	Marks.		Marks.
Davies, A. M.	2320	Younge, G. H.	1675
Hubbard, H. W.	2290	Clements, W. G.	1670
Fitzsimon, P. C. C.	2090	Babtie, W.	1625
Noding, T. E.	2065	O'Brien, R. F.	1620
Yourdi, J. R.	1992	Thiele, C. W.	1610
Culling, J. C.	1960	Nichols, F. P.	1580
Hackett, R. J. D.	1955	Cox, T.	1570
M'Geagh, R. T.	1950	M'Laughlin, J.	1570
Trewman, G. T.	1910	Fowler, R.	1560
Johnston, H. H.	1900	Creagh, S. H.	1510
Wilson, E. M.	1900	Lambkin, F. J.	1500
Risk, E. J. E.	1895	Reade, W. L.	1490
Davies, J. D.	1880	Peard, H. J.	1475
Birrell, W. G.	1850	O'Grady, G. S.	1455
Dundon, M.	1840	Rennie, S. J.	1425
Lingard, T. R.	1830	Carmichael, J.	1405
Magrath, C. W. S.	1830	Farmer, E. D.	1390
Lane, A. V.	1780	Creagh, G. W. B.	1370
Beatty, J. W.	1740	Wilkinson, F. T.	1370
Weston, G. E.	1695	Semple, J.	1345

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Feb. 24th:—

Sicard, William Edgar, Trinidad.
Young, James Vance, Maharafelt, Ireland.

The following gentlemen also on the same day passed the Primary Professional Examination:—

John Davies, Guy's Hospital; Arthur Dening, Queen's Hospital, Birmingham.

THE Baroness Burdett-Coutts has contributed £50 towards the funds of the Parkes Museum of Hygiene.

THOMAS HAMILTON MOORHEAD, M.D., of Errigle, Cootehill, has been appointed to the Commission of the Peace for the county Cavan.

CAMBRIDGE UNIVERSITY.—On the 24th ult. the degree of Bachelor of Medicine was conferred on Henry Richard Hutton, St. John's.

MR. W. INGLIS MASON of the Snelbury Union, Suffolk, has received the Government grant for successful vaccination (fourth time).

THE governors of the bequest of the late Mr. H. Heywood (who left about £26,000 for the benefit of the sick poor of Burslem) have appointed a committee to inquire and report as to a site upon which a hospital can be built.—*Charity Record.*

AT the meeting of the Ophthalmological Society, on the 10th inst., the Discussion on the Relation between Optic Neuritis and Intracranial Disease, of which notice has been given, will take place. Dr. Hughlings Jackson will introduce the subject, and Dr. Stephen Mackenzie, Mr. Hutchinson, Dr. Buzzard, Dr. Greenfield, Mr. Walter Edmunds, Dr. Gowers, Dr. Brailey, and others are expected to speak.

MIDDLESEX HOSPITAL.—The report read at the annual meeting of the subscribers of this institution gave a gloomy account of its financial condition. It was intimated that unless the coming year witnessed an improvement in this respect, it would be necessary to temporarily close one male and one female ward. It is sincerely to be hoped that such a step may be averted by the timely generosity of the public.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest*

ACLAND, T. D., M.B., M.R.C.S.E., L.R.C.P., has been appointed House-Physician to St. Thomas's Hospital.

ANDERSON, H., M.B., C.M., has been appointed Medical Officer to the Bellinge District of the Wigan Infirmary.

ARCHER, E. J., B.A., M.B., M.Ch., has been appointed a Surgeon to the Oddfellows' Club, Southampton.

BEEVOR, W. C., M.B., M.R.C.S.E., has been appointed House-Surgeon to Newark-on-Trent Hospital, vice J. Reckett, resigned.

BUTLER, H. P., M.R.C.S.E., L.R.C.P., has been appointed House-Surgeon to St. Thomas's Hospital.

CARPENTER, A. B., M.R.C.S.E., L.R.C.P., has been appointed House-Surgeon to St. Thomas's Hospital.

COLLIER, M. P. M., M.R.C.S.E., L.R.C.P., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

ELLIS, J. L., L.K.Q.C.P.I., has been appointed Medical Officer for the Mallwyd District of the Dolgelly Union.

EXHAM, A. R. F., M.B., B.Ch., L.M.K.Q.C.P.I., has been appointed Medical Officer to the Fifth District of the Drayton Union.

FIRMAN, C. G., L.F.P.S.G., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Hatfield District of the Dunmow Union.

FLETCHER, J. S., M.D., M.R.C.S.E., L.S.A.L., has been reappointed Honorary Physician to the Hospital for Consumption and Diseases of the Throat, Manchester.

GARMAN, J. C., L.R.C.P.Ed., L.R.C.S.Ed., L.S.A.L., has been appointed Assistant Medical Officer to the Highgate Infirmary, vice E. C. Cripps, M.R.C.S.E., L.R.C.P.L., resigned.

HODGKINSON, A., M.B., C.M., has been reappointed Honorary Physician to the Hospital for Consumption and Diseases of the Throat, Manchester.

HOVELL, T. M., F.R.C.S.Ed., has been appointed Surgeon to the Throat and Chest Hospital, Golden-square.

HUTTON, H. R., M.B., L.S.A.L., has been appointed House-Physician to St. Thomas's Hospital.

JEFFREYS, R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Districts of Brampton and Walton, Chesterfield Union.

JONES, Mr. E. W. T., has been reappointed Public Analyst for the Borough of Wolverhampton for one year.

JONES, J. Ff., L.F.P.S.G., L.R.C.P.Ed., L.S.A.L., has been appointed Medical Officer for the Llanegryn District of the Dolgelly Union.

KNIGHTS, Mr. J. W., has been reappointed Public Analyst for the Borough of Cambridge till Jan. 1st, 1882.

LLOYD, T. F., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Second District of the Reigate Union.

LUNN, J. R., L.R.C.P., M.R.C.S.E., L.S.A.L., has been appointed Resident Accoucheur to St. Thomas's Hospital.

PHILLIPS, L. W. K., M.R.C.S.E., L.S.A.L., has been appointed Resident House-Surgeon to the Western Branch of the Brighton and Hove Dispensary, vice Buckle, resigned.

POOLEY, T. A., B.Sc., F.C.S., has been appointed Public Analyst for the County of Essex.

POTTER, H. P., F.R.C.S., L.S.A.L., has been appointed Medical Officer for the Workhouse and Infirmary of St. Mary Abbotts', Kensington.

SMITH, R. P., M.B., B.Sc., L.R.C.P., M.R.C.S.E., has been appointed Demonstrator of Practical Physiology in the St. Thomas's Hospital Medical School.

SOUTHEY, A. J., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer for the Harmondsworth District of the Staines Union.

STEWART, T. G., M.D., F.R.C.P.Ed., has been appointed Consulting Physician to Heriot's Hospital, vice Sir R. Christison, resigned.

SWALE, H., M.R.C.S.E., L.R.C.P., has been appointed Junior Assistant House-Physician to St. Thomas's Hospital.

VINRACE, F., M.R.C.S.E., has been appointed House-Surgeon to the Queen's Hospital, Birmingham, vice J. W. Moore, resigned.

WADE, A. B., M.B., C.M., M.R.C.S.E., L.S.A.L., has been appointed a Surgeon to the Oddfellows' Club, Southampton.

WALTERS, L. R., M.R.C.S.E., L.S.A.L., has been appointed Senior Assistant House-Physician to St. Thomas's Hospital.

WHITE, P., M.B., C.M., M.R.C.S.E., has been appointed Senior House-Surgeon to the Halifax Infirmary.

WINTERBOTTOM, A. T., M.R.C.S.E., L.R.C.P.Ed., L.M., has been appointed Resident Obstetric and House-Surgeon to St. Mary's Hospital, Manchester, vice Wm. Walter, M.D., elected Honorary Surgeon.

YOUNG, A. H., M.B., C.M., has been appointed Honorary Surgeon to the Hospital for Consumption and Diseases of the Throat, Manchester.

Births, Marriages, and Deaths.

BIRTHS.

GRAYSON.—On the 25th ult., at The Poplars, Rayleigh, the wife of F. Dorrell Grayson, M.R.C.S.E., of a son.

TAYLOR.—On the 26th ult., at Champion-park, Denmark-hill, the wife of William Bramley Taylor, Esq., of a daughter.

WALKER.—On the 23rd ult., at Shrubland House, King Edward-road, Hackney, the wife of W. Newman Walker, jun., Esq., M.R.C.S.E. &c., of a daughter.

MARRIAGES.

ALLSHORN—WHITEHEAD.—On the 22nd ult., at St. Andrew's Church, Sheffield, by the Rev. E. B. Chalmers, D.D., assisted by the Rev. F. W. Goodwin, M.A., Adolph H. Allshorn, M.D., of 90, Dalston-lane, London, to Feronce Ada, third daughter of the late William Whitehead, Esq., of Sharrow Head, Sheffield.

BUCKLE—WHEELER.—On the 1st inst., at Londwater Church, by the Rev. W. P. Woollcombe, Vicar, assisted by the Rev. F. B. Ashley, John Buckle, M.R.C.S.E., of Great Bardfield, Essex, to Katherine, daughter of the late Henry Wheeler, Esq., of Beechwood, Londwater, Wycombe.

GREATHEAD—MERRIMAN.—On the 25th January, at Uitenhage, Cape of Good Hope, John Baldwin Greathead, M.B., of Grahamstown, to Esther Louisa Merriman, youngest daughter of the Bishop of Grahamstown.

RENDLE—BIRT.—On the 26th ult., at St. Mary's, Bryanston-square, George, eldest son of William Rendle, F.RC.S.E., of Treverbyn, Forest-hill, to Emily Mary, eldest daughter of the late Daniel Birt, of Lee.

SPENCE—BENNETT.—On the 23rd ult., at St. Matthew's, Redhill, James Beveridge Spence, M.D., Medical Superintendent of the Burntwood Asylum, near Lichfield, to Elizabeth Roebuck, eldest daughter of Richard Bennett, Esq., of Redhill, Surrey.

DEATHS.

AVENT.—On the 21st ult., at Lansdown-place, Plymouth, Nicholas Avent, M.R.C.S.E., late of H.M. 66th Regiment, and son of the late Nicholas Bastard Avent, Surgeon, of Modbury, Devon, aged 46.

BURN.—On the 20th ult., at The Cedars, Shirley, Southampton, of heart disease, George Burn, M.D., C.B., Inspector-General of Hospitals and Fleets (Retired), aged 70.

MACKENNA.—On the 24th ult., at Great Marlborough-street, John William MacKenna, Esq., M.D., L.F.P.S., L.M., in his 78th year.

THOROLD.—On the 24th ult., at Windsor Villas, Plymouth, Ellis Frederick Thorold, Esq., M.A., M.D., eldest son of the Rev. Henry Baugh Thorold, of Hougham-cum-Marston, Lincolnshire.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, March 7.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Cetacea."

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

MEDICAL SOCIETY OF LONDON.—7 P.M. General Meeting for the Election of Officers and Council.—8½ P.M. Ordinary Meeting, when Dr. C. Theodore Williams will read a paper "On the Pathology and Treatment of Diarrhœa in Phthisis;" and Mr. J. C. Wordsworth, "On some Defects of Sight, said to be due to Railway Accidents."

Tuesday, March 8.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Edward A. Schäfer, "On the Blood."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8 P.M. Dr. Hilton Fagge, "On a Probable Cause of Lead Colic."—Mr. Barwell, "On Experience and Specimens of the Ox Aorta Ligature, and some Remarks on the Variability of Catgut."

Wednesday, March 9.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Cetacea."

HUNTERIAN SOCIETY.—7.30 P.M. Council Meeting.—8 P.M. Mr. Clement Lucas, "On Cases of Trephining."—Dr. Herman, "On Prolapse of the Ovaries."

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. A. D. Michael, "On a Species of Acarus believed to be unrecorded."

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND SCIENCES.—Mr. William Arnot, "On Improvements in the Treatment of Esparto for the Manufacture of Paper."

Thursday, March 10.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

ROYAL INSTITUTION.—3 P.M. Rev. W. Houghton, "On Cuneiform Characters."

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 P.M. Microscopical Specimens.—8.30 P.M. Discussion on "The Relation between Optic Neuritis and Intracranial Disease," to be opened by Dr. Hughlings Jackson.

Friday, March 11.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1¼ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Cetacea."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Gulstonian Lectures: Dr. Coupland, "On Anæmia."

ROYAL INSTITUTION.—8 P.M. Prof. R. S. Blackie, "On the Language and Literature of the Scottish Highlands."

CLINICAL SOCIETY OF LONDON.—8½ P.M. Mr. Berkeley Hill, "On a Case of Fracture of the Spine treated with Sayre's Jacket."—Mr. Barwell, "On a Case of Excision of the whole Tongue by means of a small Supra-hyoid Wound, with remarks on the best material for the Loop of Ecraseurs."—Mr. Berkeley Hill, "On a Case of Round-celled Sarcoma, in which no repetition of the Disease took place during the remainder of the Patient's Life—namely, six years after the Operation."—Dr. Radcliffe Crocker, "On a Case of General Bronzing of the Skin without Constitutional Symptoms."—Mr. R. W. Parker will show (1) a Child with Pulsating Tumour on the Forehead, and (2) Three Brothers with Undescended Testicle.

Saturday, March 12.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Mr. R. S. Poole, "On Ancient Egypt."

Notes, Short Comments, and Answers to Correspondents.

THE present issue of THE LANCET is the **three-thousand-and-first** number, the thirty-sixth of the **fifty-eighth year** of its publication.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

Mr. A. G. Chitty.—We are sorry that the printed reports do not include the points raised by our correspondent, on which the coroner seems to hold peculiar views.

Mr. Roger Hughes.—Consult Murchison on "Diseases of the Liver," Dickinson on "Diseases of the Kidney," and other such authorities. Dr. Richardson's works, of course, bring a heavier accusation against "alcohol and its effects on the human system."

A. B.—The prefix mentioned belongs properly only to graduates of a university, and there is no probability of any legislation altering this state of things.

B. H. H., *B. W. A.*, and *Junior* have not enclosed their cards.

PARTIAL DISLOCATION OF THE HEAD OF THE HUMERUS FORWARDS.

To the Editor of THE LANCET.

SIR,—On the evening of the 5th inst. I was called to a female patient, aged thirteen years, who had the same morning fallen downstairs. She complained of pain in the right shoulder. The symptoms elicited by examination were slightly limited movement, she being able to raise the arm outwardly almost to the horizontal, but could not approximate it to the side nearer than about five inches, any forward movement being painful. The length from acromion to external condyle of humerus was not appreciably different from that of the opposite side. A slight prominence existed on the front of the shoulder, less than might even have been accounted for by a sprain, but more defined, as if the result of a contusion. There was, however, no discoloration. By grasping the limb above the elbow with the right hand, the shoulder being embraced firmly above by the left hand, two fingers in front, the thumb behind, slight pressure caused the head of the bone to at once slip into its place. The movement of the head of the humerus on reduction was unmistakably evident both to myself and to the patient, the functions of the joint being immediately restored.

The only cases I remember to have seen described are two—one by Mr. Le Gros Clark, and the other by Mr. Smith. Since the condition appears to be a rare one, whose existence was at no very distant date disputed, perhaps you may think the present case worthy of record.

I am, Sir, yours, &c.,

Gorton, Feb. 7th, 1881. EDWD. KENNEDY.

THE FROST OF JANUARY, 1881.

A PAPER was read at a recent meeting of the Meteorological Society by Mr. William Marriott, F.M.S., on the frost of January of the present year. The author pointed out that the severe frost of the 7th to the 26th was remarkable for its unexpected appearance, its long continuance, and its sudden breaking up. The weather during the first week of January was comparatively mild, but frost set in over the north of Scotland on the 5th. The author then gave the lowest thermometrical readings from about 300 stations in the United Kingdom for each day of the frost, which were marked upon diagrams, clearly showing the relative severity of the weather experienced in each district. The lowest readings were 15° at Garstang on the 16th, and 22° at Blackadder, 16° at Kelso, 15° at Stobo, 11° at Thirlestane Castle, and 10° at Melrose on the 17th. Reference was also made in detail to the rivers and lakes which had been frozen over and to other incidents, proving the remarkably low temperatures which had occurred. Some idea of the intensity of the frost may be gathered from the fact that in the south of Scotland the temperature fell below 10° on more than 11 occasions, below 20° on 19 occasions, and was below 32° on 25 to 29 occasions. In the London district readings below 10° occurred on 2 or 3 days, below 20° on 10 days, and below 32° on 20 days. In Ireland temperatures below 10° were registered on 6 or 7 occasions, below 20° on 12 or 14 occasions, and below 32° on 22 to 24 occasions. No place in the British isles was exempt from the frost; even at Scilly the temperature was below 32° on 3 days, the lowest being 29° on two occasions. The winter seaside health resorts afforded no protection from the frost; at Penzance the temperature fell below 32° on 10 occasions, at Torquay on 11 occasions, and was below 20° on 6 occasions; at Ventnor it was below 32° on 19 occasions, and below 20° on 3 occasions; and at Bournemouth it was below 32° on 23 and below 20° on 10 occasions. The heavy falls of snow prevented the frost from penetrating far into the ground, but where the snow was cleared away the temperature of the soil fell considerably. A diagram was exhibited showing the mean temperature of January in the neighbourhood of London for each year from 1774 to 1881, from which it appeared that the low mean temperature of 31·6° for January had only been surpassed on two occasions, and that the three years 1879–81 have been very cold, the mean for this period being only 32·2°. There is no instance during the past 100 years of any three consecutive Januarys having so low a mean temperature.

DESQUAMATION AFTER SCARLATINA.

To the Editor of THE LANCET.

SIR,—While this subject is under discussion in your columns I should like to call attention to the effect belladonna seems to have upon the character of the desquamation. Having heard belladonna much vaunted as a prophylactic in scarlatina, I decided to try its value by giving it in small doses (quarter minim of the tincture every four hours) to four children in apparent health who were residing in the same house as a child suffering from scarlatina. The result was not satisfactory, in so far as it did not prevent them from taking the fever, for all of them had it one after the other, the last having taken the belladonna for over a week before the scarlatina rash appeared; but in each case I found that the desquamation was in fine branny scales, instead of the large flakes usually seen after scarlatina, and which were well seen in the case of the first child, who had not had any belladonna. This led me to try the drug in cases where the rash had already appeared, and in each case I have obtained the branny kind of desquamation. I have now treated over twenty cases, and in all I have had the same result, while a number of cases during the same epidemic untreated by belladonna have had the usual large flake peeling. I do not find this effect from the internal use of belladonna in scarlatina mentioned in any of the works on therapeutics I have consulted, although its distinct action upon the functions of the skin, as seen in its control over the sweating of phthisis, is now fully recognised.

As a prophylactic I may add that I have given it a fair trial, having in five years been twice in the thick of epidemics of scarlatina, and although in two or three cases I have thought it must have averted the infection, the other result has so often occurred that I am inclined to regard it of but little value for this purpose. I believe it to be beneficial in the fever itself, for those cases in which it has been administered have all made good recoveries, and in each the sore-throat has been specially slight.—I am, Sir, yours faithfully,

J. ALFRED MASTERS, L.R.C.P. Lond., &c.

Hednesford, Staffordshire, Feb. 22nd, 1881.

AS bearing upon the above question, *Septic Solvent* desires to direct attention to the value of acetic acid in scarlatina. He says he has for some years adopted the practice of sponging all his scarlet fever patients with the diluted acid (one part of the strong acid to five parts of hot water), commencing the application as soon as the nature of the illness was suspected, and repeating it three times a day until the establishment of convalescence. In no case where this treatment has been carried out had there been the slightest desquamation.

MORBIFIC ODOURS.

To the Editor of THE LANCET.

SIR,—We have had a serious outbreak of small-pox here, about twelve cases, four of whom died. In two of the cases I noticed the following phenomenon, of which I should be glad to have an explanation:—

T. M——, a labourer, was working in a brickfield when some rubbish was shot close behind him. He immediately complained how horribly the rubbish smelt, was violently sick, and felt so ill that he was compelled to give up work and go to bed. The same evening he had a rigor, and in a few days the small-pox eruption made its appearance. Subsequently he informed me that his perspiration smelt just like the rubbish that had made him sick. I, however, noticed no peculiarity in the smell.

J. B——, paperhanger, went into a room with a companion in which a small-pox patient had lain. He immediately complained of the dreadful smell, was very sick, went straight home to bed, and in due course the eruption appeared on him.

In neither case was the smell complained of noticed by the companions, who also escaped the disease. I am happy to say that both men did well. I remain, Sir, yours obediently,

ALFRED BERNARD, M.R.C.S.

Queen's-road, Upton-park, E., Feb. 28th, 1881.

Subscriber.—"Boston Medical and Surgical Journal," Nov. 11th, 1880.

L. M.—He cannot.

T. J. G.—Any qualified medical practitioner may be consulted in the case.

Dr. H. Kennedy (Dublin).—The book has been received, and will shortly be noticed.

COMPENSATION FOR RAILWAY INJURIES.

To the Editor of THE LANCET.

SIR,—A friend of mine was injured in a railway collision, and his condition was such that the company privately allowed him £415 out of a claim made for £500. The medical agent of the company who "settled" the matter with my friend saw his tottering condition, and, in spite of his protests, insisted that perfect recovery would result in two years at the utmost. My friend is now in an advanced state of locomotor ataxy, never having recovered his health since the accident in 1875. He has had regular explosions of the usual symptoms of spinal injury up to the recent continuous and, I fear, final stage of the confirmed disease. He was induced to sign a document absolving the Company from all further liability. This payment of £415 was at last made as the result of a threat of legal proceedings. The Company has lately been applied to for moderate further compensation during total disability, and has absolutely refused it without examination of the patient.

I wish to ask you and your readers if, 1st, the "document" will hold water in a court of law? and, 2nd, if any such cases have arisen in which a jury have adjudged adequate further compensation?

I am, Sir, yours, &c.,

Shepton Mallet, Feb. 28th, 1881. F. PORTER SMITH, M.B. Lond.

FOREIGN BODY IN THE INTESTINES.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 12th Surgeon-Major O'Brien has reported the case of a soldier's son who had swallowed a pin. Will you allow me to mention the case of a youth who swallowed a needle in a similar way? In March, 1880, Mr. N——, a linendraper in this village, came to me in a great state of alarm, telling me his son, a boy about six years old, whilst playing with a needle placed it in his mouth, and by some means swallowed it. Of this they were certain, as he was seen to place it in his mouth, and it suddenly disappeared. The father was very anxious that I should supply him with some strong aperient, as he said, to work it through him, and was very much surprised when I advised him not on any account to give the child purgative medicines, but to give him principally dry food, keep him quiet, and well watch every motion for some days. This they did, and on the fourth day were rewarded by finding the needle pass entire, though of a somewhat altered appearance, it having become quite blackened during its voyage through the canal. I need not say the child recovered without a single bad symptom, but had the father given the strong dose I believe it would have terminated very differently.

I am, Sir, yours truly,

Shirley, Southampton, Feb. 17th, 1881. RICHARD J. CÆSAR.

ACUTE RHEUMATISM AS A SEQUENCE OF TONSILLITIS.

To the Editor of THE LANCET.

SIR,—I was glad, amongst others, to see this subject brought forward by Dr. Fowler, as I believe it is not a generally known fact. Some time ago I had a case of tonsillitis in a young married woman, followed in the course of a few days by a severe and, as it eventually proved, a fatal case of acute rheumatism, seriously affecting the heart. The interval in my case, between the throat symptoms having passed away and the commencement of the rheumatism, was only about two or three days. I am, Sir, yours faithfully,

Feb. 9th, 1881. H. P. ILDERTON, L.R.C.P. Edin.

"THE APPLICATION OF WARMTH TO THE HEAD."

To the Editor of THE LANCET.

SIR,—I should have said that in cases of suspended animation, as from drowning, I would suggest applying considerable warmth to the head and likewise to the back of the neck and the spine, so far as to include the phrenic and all the respiratory nerves, and this with the view of either restoring circulation or relieving congestion and promoting the regeneration of nervous force at their origins, and in the brain and spinal cord. Proper warmth to the other parts of the body and other approved means of restoration to be used, of course, as well. I had not noticed this subject mentioned, and therefore I hoped to make a useful suggestion. I remain, Sir, your obedient servant,

Chilton-Polden, Feb. 1st, 1881. CHARLES YOUNG, M.R.C.S.

THE DETERMINATION OF SEX.

To the Editor of THE LANCET.

SIR,—The following case seems to me to have considerable interest in relation to this question, which is now under discussion:—A man, at present in the Sussex County Hospital, has only two phalanges on each of his forefingers. His mother had the same deformity. He has six brothers; the two eldest have no deformity, but the other four have. He has two sisters who have no deformity. Of his children, the eldest, a girl of thirteen, and the third, a girl of three and a half, have, like their father, only two phalanges; while the second, a boy of five, and the youngest, a boy of eight months, have the normal number.

I am, Sir, yours, &c.,

Brighton, Feb. 19th, 1881. JOHN C. UHTHOFF, M.D. Lond.

DEATH FROM CHLOROFORM.

To the Editor of THE LANCET.

SIR,—I beg to report a death from chloroform, which occurred at this hospital on Saturday, Feb. 19th. The following are the particulars of the case:—

J. W——, a cabman, aged fifty-five, but looking much younger, came to the hospital suffering from a dislocation of the left shoulder of two days' standing. Attempts to reduce it having failed, chloroform was given. During the administration the patient struggled a good deal, but no symptoms of danger appeared. Anæsthesia was produced in about three and a half or four minutes. The inhalation was then discontinued, and the dislocation reduced. Immediately afterwards the breathing became stertorous, the face congested, and the pulse suddenly stopped. Artificial respiration was kept up for half an hour, an enema of brandy given, and galvanism employed without effect. The post-mortem examination showed considerable fatty change in the heart, with some fibroid thickening of the valves, which, however, were all perfectly competent. The lungs and other organs were much congested, but healthy. The reports of the inquest which have appeared in the papers were, of course, much garbled, and in some points entirely opposed to the real facts. I may mention that the chloroform was given on a cone of flannel, and about two drachms were used.

I am, Sir, yours faithfully,

R. D. H. GWILLIM, M.R.C.S., House Surgeon.

St. Mary's Hospital, Paddington, March 1st, 1881.

Anxious Inquirer should consult a medical adviser.

Inquirer had better make application at the office of the association, St. John's-gate, Clerkenwell.

M.R.C.S.—We regret that we have not space to print the letter. The case is not an unusual one either in its nature or in its duration.

Aboe should consult a surgeon.

Broad Arrow.—We think it would be advisable to wait until the effect of the new Warrant has been fairly tested.

Scrutator.—We must refer our correspondent to the General Medical Council.

Registered.—We should say that our correspondent is fully qualified.

VACCINE LYMPH.

To the Editor of THE LANCET.

SIR,—A great number of medical men apply to me for animal lymph from the Government Institution of Vaccine at Brussels. They are either not aware or may have forgotten that Mr. Ed. Darke, of 3, Hemming's-row, Charing-cross, London, W.C., is my only agent for the supply in the United Kingdom, and it is to him that all applications must be made. If you will have the kindness to insert this letter in the next number of your journal, it will be the means of saving fruitless trouble to many members of the profession.

I am, Sir, your obedient servant,

Brussels, Feb. 25th, 1881. DR. WARLOMONT.

N.B.—All orders must be transmitted before the Tuesday in each week. The price of the large tubes or points is two shillings each, and one shilling for the small ones; payment to be made by Post-office orders.

Economy of Fuel.

Our contemporary, *Design and Work*, publishes a series of data from experiments made by Mr. A. Percy Smith, of the Temple Observatory, Rugby, which go to show that the use of gas for cooking in properly constructed apparatus is much more economical than the use of coal.

SALICYLATE OF CINCHONIDIA AND OF QUINIA.

To the Editor of The Lancet.

Sir,—Dr. Hewan's interesting observations in The Lancet of Saturday last concerning salicylate of quinine are likely to be confirmed by others, for in many cases salicylic acid and quinine seem both to be indicated, and excellent therapeutical results have been reported from the one and the other, while a combination has sometimes succeeded after the failure of either. Upon the introduction of salicin and salicylic acid for rheumatism I tried them alternately with quinine. At length salicylate of quinine was manufactured. Dr. Hewan and others who have found it so efficacious will no doubt welcome another salt which I beg now to introduce—viz., salicylate of cinchonidia. This less costly preparation is very efficacious. Five grains may be given every two, three, or four hours, or in chronic cases three or four times a day. In severe neuralgic and rheumatic pain ten grains or more as an initial dose may be given. I have sometimes found five grains produce "singing in the ears," lasting for several hours, "exactly like the quinine medicine." At other times several doses were given before this occurred. The salt contains nearly one-third of its weight of salicylic acid, and it is of course incompatible with iron; it is rather insoluble, and so the taste is less pronounced than that of quinine. It can be given in pills or in wafer-paper, or in suspension. I give the solid drug in the form of Wyeth's compressed tablets, a very convenient method for administering various remedies. The tablets can be swallowed like pills, and, on account of the insolubility of the cinchonidia salt, the bitter taste is not perceived. Of course, for any special purpose they could be crushed to powder, but this would scarcely ever be desired. In neuralgia and in chronic rheumatism salicylate of cinchonidia deserves further trial. I have not employed it in acute rheumatism, but there must be many cases in which it might replace with advantage other salicylates.

I am, Sir, yours, &c.,

Dean-street, Park-lane, W., Feb. 21st, 1881. Prosser James.

P.S.—Having mentioned Wyeth's tablets in the above, let me take the opportunity of adding that I suggested the compression of iodide and of bromide of potassium by the same process, and such tablets (five and ten grains) are now in the market. Of course, it is usually desirable to give these salts dissolved in a full quantity of fluid, but to travellers and other persons the compressed tablets will often prove specially convenient.

STRUCTURE OF THE ANAL MUCOUS MEMBRANE.

To the Editor of The Lancet.

Sir,—In reference to this subject, I would beg leave to state that the late William E. Horner, Professor of Anatomy in the University of Pennsylvania, Philadelphia, was in the habit of demonstrating the existence of the pouches referred to in The Lancet of Jan. 29th, 1881 (page 187), and of Feb. 3rd (page 216), to his class as long ago as 1833, when I was a member of his class, and are described in his work on general anatomy, published in 1833. The late Dr. Geo. W. Norris, of Philadelphia, operated upon me in 1854 for purulent discharge from the anus, dividing the pouches by a curved knife such as Mr. Clegg states is used by Mr. Bickersteth. The division of these pouches has long been practised by the surgeons of the United States.

I am, Sir, yours very respectfully,

Ferrara, Italy, Feb. 8th, 1881. Morris S. Wickersham.

Erratum.—In our report of the meeting of the Clinical Society on the 11th ult., the question put by Dr. A. E. Longhurst in relation to Dr. Sutherland's paper was wrongly attributed to Dr. Robinson.

Communications, Letters, &c., have been received from—Dr. Buzzard, London; Dr. Pountney, Lytham; Mr. P. Miall; Mr. Gwillim, London; Mr. C. Lucas, London; Mr. Gabb, Bewdley; Mr. Barnard, London; Mr. MacCormac, London; Dr. Holden, Sudbury; Dr. Spencer, Bath; M. Berthier, Paris; Mr. Nunn, Bournemouth; Mr. A. B. Morris, Kurseong; Dr. Goyder; Dr. Lawrence, Montrose; Dr. F. W. Smith, Leamington; Dr. Filipowier, Warsaw; Mr. W. Wilson, Carlisle; Dr. F. P. An entire Page	5 5 0

The above Scale of Charges is arranged upon the basis of the classification adopted in the Index.

Notice.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "The Lancet General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in The Lancet.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.

The postal arrangements relating to the distribution of The Lancet will be considered from time to time in the interests of subscribers.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

A Lecture
ON THE
PATHOLOGY OF THE OBSTRUCTION OF THE CIRCULATION OF THE BLOOD IN THE LUNGS,
AND OF THE FAILURE OF THE HEART'S ACTION, WHICH ARE LIABLE TO OCCUR DURING THE ADMINISTRATION OF CHLOROFORM.

Delivered at University College Hospital on Thursday, January 20th, 1881,

By WHARTON JONES, F.R.C.S., F.R.S.,
PROFESSOR OF OPHTHALMIC MEDICINE AND SURGERY IN UNIVERSITY COLLEGE, AND OPHTHALMIC SURGEON TO THE HOSPITAL.

GENTLEMEN,—Of all the various bodies the vapour of which has been administered by inhalation to produce insensibility to pain during the performance of surgical operations, ether, chloroform, and ethidene dichloride are those which have stood their ground best in the estimation of practitioners. Of these three anæsthetics chloroform has proved the most dangerous, and ether the least so. Leaving ethidene aside, I propose to confine my observations to the effect of inhalation of the vapour of chloroform and of ether on the blood in the vessels of the lungs, and on the action of the heart. As data, I take the facts recorded in the report by the Committee of the British Medical Association, recently published. And, first, I shall direct your attention to the phenomena which admit of being observed by direct inspection of the lungs and heart of frogs anæsthetised with chloroform and ether. But introductory to this let me briefly describe to you the phenomena of the pulmonary circulation in the water-newt and in the frog as observed under the microscope in the natural state. The lung of the water-newt is of simpler construction even than that of the frog, but the distribution of the vessels in its walls and the mode of circulation of the blood in them are similar. [Here a drawing was shown representing the vessels of the lung of the water-newt and of the frog, drawn from the life.]

The ramifications of the pulmonary artery occupy an external stratum of the wall, and the radicles of the pulmonary vein an internal stratum, while the capillary network is interposed between the two. Into this capillary network, occupying the intermediate stratum, the extreme arterial ramifications open, and from it the venous radicles arise. In thus opening into the capillary network, the extreme arterial ramifications subdivide abruptly, whilst by an equally abrupt union of capillaries the venous radicles have their origin. Viewing the circulation of the blood in the lung from the outside, we come, in adjusting the microscope, first on the streams in the small arteries, then underneath them, on the streams in the capillary network; and lastly underneath the latter, on the streams in the veins. The streams in all the vessels may, indeed, be seen under the adjustment for the capillary network; but with an objective one-eighth of an inch they are seen, each stream most distinctly, of course, under the adjustment for its own level. The width of the meshes of the capillary network varies somewhat according to the degree of distension of the lung with air. The pulmonary artery has thickish muscular walls; but in the course of my observations I never actually saw constriction of any of its branches occur, as we so often see in the case of the arteries of the frog's web. I have, however, seen arterial ramifications with their calibre already somewhat constricted here and there, while some presented their calibre rather wider than that of the trunk whence they sprang. At the extremity of the pulmonary sac the termination of the main trunk of the pulmonary artery was in one case dilated in a varicose manner at three different points. The pulmonary artery and its branches are accompanied by a nerve and its branches, in the same way as are the arteries of the frog's web. The walls of the pulmonary veins are not so thick as those of the arteries. Here and there the calibre of a vein might be seen slightly constricted, as if by the contraction of a muscular coat.

At the commencement of the sittings at which the particulars I have now described were noted I found the flow of blood in the vessels rapid and uniform. The white corpuscles were mingled together with the red in the streams, but towards the end of a sitting the circulation was observed to have become slower, and white corpuscles were seen to settle on the walls of the vessels—both arteries and veins—in small numbers. None were seen to escape from the interior by boring through the vascular wall, but I have seen extravasation by rupture. In an artery leading to capillaries which had become obstructed by congestion and stagnation of blood-corpuscles in their interior, the blood thereby arrested in its course was seen to oscillate to and fro rhythmically with the systole and diastole of the heart. This oscillating collection of blood, which consisted of a large proportion of plasma with few red corpuscles, but a considerable quantity of colourless corpuscles, accumulated on one side of the vessel, corresponds with those collections found in the truncated ends of divided arteries, and designated by the name of "internal clot."

To speak next of the frog's lung and the phenomena of the circulation of the blood in it. The frog's lung represents a sac on the inside of the wall of which there are small compartments formed by reduplications of the lining membrane. Externally the lung is mapped out into polygonal spaces which correspond to the parietal compartments, and are bounded by anastomosing bands composed of fibrous tissue enclosed within the reduplications of membrane which form the pulmonary walls. It is in these polygonal spaces of the pulmonary wall corresponding to the parietal compartments that we see the circulation going on in the capillary network. As in the lung of the water-newt, the arterial ramifications form an external stratum, and the venous radicles an internal stratum in the wall of the pulmonary sac, while the capillary network occupies an intermediate place. I have not observed in the frog's lung, any more than in that of the newt, constriction of the calibre of the arteries take place except in a slight degree. As in the lung of the water-newt, the flow of blood in the vessels of the frog's lung is rapid and uniform. The arteries and veins compared with those of the web of the animal's hind-foot appear fuller and more distended with red blood. A point to be particularly remarked in regard to the pulmonary circulation in both the newt and the frog is the great sensitiveness of the red corpuscles to the action of impure air, as manifested by the readiness with which they become aggregated and stagnant in the capillaries. This I long ago showed by blowing carbonic acid gas on the lung of a frog disposed under a microscope.[1] Obstruction of the pulmonary circulation, then, has its origin in the capillaries by aggregation and stagnation of the red corpuscles therein under exposure to the action of impure air.

In coming now to a consideration of the pathological phenomena which admit of being observed by direct inspection of the lungs and heart of anæsthetised frogs, it is to be premised that, while in mammiferous animals complete obstruction of the pulmonary circulation necessarily prevents any further affluence of blood to the left side of the heart, and thence to the system by the aorta and arteries, affluence of blood to the system is not necessarily so prevented in frogs; the reason being that the heart of the frog has only a single common ventricle into which the impure blood which the right auricle receives from the system and the pure blood which the left auricle receives from the lungs are poured. The impure and the pure blood thus received into the common ventricle are, in the natural state, there mingled, and the mixture is sent by its contraction, some back to the lungs by the pulmonary artery, and some to the system at large by the aorta. When the circulation through the lungs is completely obstructed in an asphyxiated frog, you thus see that, though no blood can be received from the lungs into the left auricle, the venous blood which is received from the system at large by the right auricle can pass therefrom into the common ventricle, from which cavity of the heart the blood is free to pass off by the aorta to the system, but cannot be propelled back into the obstructed vessels of the lungs.

Let us now endeavour to trace the correlations of the phenomena presented in an experiment on a frog subjected to the influence of chloroform, described in the report under notice, and which was this: The frog being anæsthetised with chloroform until reflex action was suspended, it was so disposed that one of its lungs and the web of the right foot might be observed under a microscope. By means of a cannula introduced into the glottis, the lung was first inflated with pure air, and in this state the circulation in its walls was seen, on examination under the microscope, to be active. Air mixed with chloroform vapour was now introduced by artificial respiration through the cannula, whereupon the flow of blood in the capillary network was seen to become, first, less rapid, and then to cease. A few seconds after this the flow of blood in the arteries leading to the obstructed capillary network, and in the venous radicles coming from it, was found to have ceased also. This stoppage of the circulation in the lung I interpret thus. For want of due aeration of the blood, and perhaps by a special action of the chloroform also, the red corpuscles became aggregated and stagnant in the capillaries, so as to block them up—an effect similar to that produced by the direct action of carbonic acid gas on the lung of a frog, in the experiment to which I have before referred. Consequent on the progressive obstruction of the pulmonary circulation in the frog under chloroform, the heart no longer received aerated blood, and the venous blood which the common ventricle received from the right auricle passed off by the aorta into the systemic arteries, in which it was, however, feebly driven, in consequence of the impaired energy of the heart, now no longer supplied with pure blood. Soon after the stoppage of the circulation in the lung, stagnation of the blood in the capillaries of the web was found to have taken place. This, I consider, was owing to aggregation of the red corpuscles of the impure blood, favoured by the small degree of force with which it was now propelled through the system.

---

[1] British and Foreign Medical Review for October, 1842.

In continuation of the experiment under notice, artificial respiration with pure air was next employed, and in the course of eight minutes' time the contractions of the ventricle, which had fallen to four, were now increased to nine a minute. As a result of this increased rapidity of the heart's action, the blood, it is stated, was seen to begin to flow slowly in the larger vessels of the lung.

The real sequence of events in this case must, however, in my opinion, have been this: Under the influence of the pure air, the red corpuscles blocking up the capillaries of the lung by their aggregation, became less tenaciously adherent to each other and to the walls of the vessels, so that they admitted of being pushed on by the force of the heart, weakened though it was. Resolution of the congestion of the corpuscles of the blood in the capillaries thus tending to take place, the force of the heart proved sufficient to propel the blood somewhat onwards in the pulmonary artery. In proportion as the circulation in the lung was gradually becoming re-established in this manner, the power of the heart increased, and so the blood was propelled more and more freely through the vessels of the lung, and thence in a pure state to the heart, as well as to the system generally, until the circulation became fully re-established, as was found to be the case in twelve minutes more, at which time the systolic contractions had risen to fifteen in the minute. The artificial respiration thus did not operate directly on the heart, but operated first on the blood stagnant in the capillary network of the lung. Stagnation had continued in the capillaries of the web, but now the circulation was observed to become gradually re-established there also. This was, no doubt, owing to an action of the pure blood, which would now be driven onwards by the increased force of the heart, and of which the affluence to the capillaries would be permitted by a concurrent relaxation of the small arteries. The impaired activity of the heart, I have said, is owing to its not being supplied with pure blood. But the congestion and stagnation of the corpuscles in the capillaries of the lungs were not owing to the deficient power of the heart. As the full power of the heart was incapable of preventing the congestion and stagnation from taking place at the first, so in its impaired state it was still more incapable of driving onwards the blood-corpuscles, which by their aggregation had come to block up the vessels of the lungs, until by the access of pure air their adhesion to each other and to the walls of the capillaries became loosened.

In short, chloroform, when its administration proves fatal to a patient, appears to operate by first inducing stoppage of the circulation in the lungs in a manner similar to that in which carbonic acid gas operates when directly applied, as I have before stated. Failure of the heart takes place secondarily, in consequence of the interruption of the respiratory process; and, of course, if the heart be already morbidly weak, failure of its action will all the more readily take place for want of the circulation of pure blood in its walls.

From this it would seem a legitimate corollary that artificial respiration ought to precede the employment of any cardiac stimulant in a case of failure of the heart. But let it be repeated that this state of asphyxia is only gradually established, and that it is only in proportion to the obstruction of the blood in the lungs that failure of the heart's action at last takes place, the apparently sudden failure being the equivalent merely of the proverbial breaking of the camel's back by the last feather added to its burden.

The conclusion I have here deduced from the facts before me as to the occurrence of failure of the heart being subsequent to obstruction of the circulation in the lungs must be qualified if the opinion which I shall mention further on be well founded—viz., that the chloroform, with which the blood circulating in the coronary vessels in common with those of the system generally is impregnated, directly causes primary failure of the heart by paralysing its muscular power independently of any obstruction in the lungs.

I next come to the experiment on a frog subjected to the influence of ether as described in the report. The effect of ether was similar to that produced by chloroform, but the administration required to be kept up for a longer time before anæsthesia took place. In the experiment stagnation of blood-corpuscles was observed first in the capillary network, and after that stoppage of the flow of blood in the small arteries took place. Pure air being now administered by artificial respiration in substitution of the ether vapour, a flow of blood was seen to become re-established in the small arteries, and this indication of renewed activity of the heart, it is stated, was followed by dispersion of the congestion in the capillary network. But here, again, I have no doubt that, as before remarked in reference to the experiment with chloroform, the aggregation of the red corpuscles in the capillaries had first become loosened under the influence of the pure air. It was not until after the stoppage of the circulation in the lung that congestion and stagnation of blood were observed in the vessels of the web. And it was not until the circulation in the lung became re-established that the blood again flowed in the web. As was the case in the experiment with chloroform, obstruction of the pulmonary circulation was found to precede any diminution in the pulsations of the heart. This, again, shows that the stoppage of the flow of blood in the lung was not owing to primary impairment of the heart's action, but that it was dependent on stagnation of the blood-corpuscles in the capillaries of the lung, and that this arrestment of the respiratory process was the cause of the impairment of the activity of the heart. Though inhalation of a larger quantity of ether vapour than of chloroform vapour was required to produce anæsthesia, it was found that respiration with pure air more rapidly led to complete re-establishment of the circulation in the lungs under ether than when chloroform had been given. This and the fact that the heart did not become so much affected under ether, would seem to indicate that the circulation in the lungs did not become so much obstructed as it did under chloroform. The continued vigorous action under ether, which the heart is stated to have maintained, would, indeed, seem to indicate that in the case under consideration obstruction of the pulmonary circulation had not only not fully taken place, but that stimulation of the heart was caused by the ether which impregnated the blood circulating in its walls.

I now come to consider the effect of chloroform and ether on dogs and rabbits, as recorded in the report. One of the most striking effects of anæsthetic agents observed in the experiments on those animals was engorgement of the venæ cavæ and right cavities of the heart, indicating obstruction to the passage of blood through the vessels of the lungs. Under chloroform the respiration was very liable to become thus arrested, whilst the action of the exposed heart was found to cease soon after. By artificial respiration with pure air the action of the heart was resumed; but this was, no doubt, the effect of commencing re-establishment of the circulation in the lungs in the manner already contended for in the case of the frog. Under ether the action of the exposed heart was not, it is stated, found to be interfered with. This would indicate, as before observed, that the circulation in the lungs continued more or less free. In accordance with this no engorgement of the veins and right cavities of the heart is particularly mentioned as having taken place. No doubt, however, more or less impure blood—impure both from defective oxygenation and from impregnation with the anæsthetic—was during this time circulating through both lungs and system, so that there existed a moderate degree of asphyxia. This suggests the question, Is anæsthesia owing simply to a state of asphyxia, or to a more special action of the anæsthetic in addition? As bearing on this question you will call to mind the well-known fact that inhalation of atmospherical air loaded with carbonic acid gas induces a state of insensibility.

In reference to these and other clinical questions the opinion of so experienced a practitioner as my colleague Mr. Clover is of the highest value and authority. He thinks that a state of anæsthesia may be produced independently of any obstruction of the circulation in the lungs, and that anæsthetics have a special action of their own on the nervous system, though a state of asphyxia may assist the operation of this action. As to failure of the heart under chloroform, Mr. Clover is of opinion that it may take place primarily, the *modus operandi* in this case being that the blood, impregnated with chloroform, in circulating through the substance of the heart, acts as a poison to its irritability. But he at the same time allows that the heart's substance, when as yet only partially affected by the paralysing influence of the chloroform, will succumb the more readily if obstruction of the circulation in the lungs supervenes. When obstruction in the lungs occurs during the administration of ether, the action of the heart fails less quickly than under chloroform. This Mr. Clover attributes to a stimulating action which the ether, impregnating the blood, exerts on the muscular substance of the heart.

To conclude, I have not here noticed the subject of the heart's force and blood-pressure as indicated by the hæmatodynamometer in dogs under the influence of an anæsthetic. My reasons for this are—first, that, practically, it does not concern us; and, secondly, that from a physiological point of view, the indications of the blood-pressure afforded by the instrument are not, I believe, so trustworthy as has been commonly supposed. The fact is that the calculations based on observations of the rise and fall of the column of mercury in the hæmatodynamometer have been made under the erroneous impression that the whole force of the heart's action bears upon the blood in the tube inserted in the artery experimented on, whereas a part only of the force is indicated, seeing that the principal part of the *vis a tergo* comes to bear on the current of blood which is now diverted into arterial channels nearer the heart. This is shown by the fact pointed out seventy-five years ago by Dr. J. F. D. Jones, in regard to the *vis a tergo* in an artery of some size, on which a ligature was applied. The stream of blood Dr. Jones found did not continue to be impelled against the closed extremity of the artery with the same degree of force as that with which it was driven in the vessel before it was tied. He observed that the stream of blood in the artery experimented on immediately turned aside into the collateral branches of the vessel higher up. To such a diversion of the *vis a tergo* what success has resulted from tying the artery on the distal side of an aneurism is, I believe, mainly owing. To this I have to add, that under the microscope we may see in a small artery leading to obstructed capillaries, or in one which has been divided, that the current of blood readily passes off in a collateral branch of the vessel situated higher up towards the heart. (This is shown in the drawing representing the "internal clot, in divided arteries of the bat and frog.) The force of the heart in this case evidently no longer acts strongly on the column of blood which occupies the artery below the collateral branch by which the stream passes off. The only indication of pressure by the *vis a tergo* here is the oscillation of the column of blood. This column of blood in an artery leading to obstructed capillaries, whether of the lung or web of the frog, or in the upper segment of a divided artery, which may be seen oscillating synchronously with the action of the heart, corresponds, as I before remarked, in respect to the nature of the conditions under which it thus presents itself, to what has been named the "internal clot" within the ends of divided arteries. It corresponds also, you will understand, to the column of blood in the hæmatodynamometer. By the systole of the heart the column of blood I am speaking of is pressed on, but progressive motion of it being prevented, the small amount of force from the heart to which it is subjected is expended, causing merely some distension of the vessel. On the supervention of the diastole of the heart a recoil of the column of blood takes place by the elastic reaction of the wall of the vessel. In the case of an experiment with the hæmatodynamometer, the rise and fall of the column of mercury corresponds to this oscillation with distension and collapse of the vessel.

It is, however, let me repeat, only a small degree of the force of the heart which is herein exerted. Higher up in the artery towards the heart, the stream of blood passes off by some large collateral branch, and it is there that the full force of the heart's systole is expended, a degree of force which is far from being indicated by the hæmatodynamometer.

ON THE NATURE AND SEQUENCE OF THE CARDIAC AND VASCULAR CHANGES IN INTERSTITIAL NEPHRITIS.

BY GEORGE JOHNSON, M.D., F.R.S.,
PROFESSOR OF CLINICAL MEDICINE, SENIOR PHYSICIAN TO KING'S COLLEGE HOSPITAL.

IN a paper on the above subject recently published in THE LANCET (Feb. 5th and 12th), Dr. Bryan C. Waller does me the honour to confirm the accuracy of my observations with regard to the hypertrophy of the middle muscular coat of the arterioles in the kidney and other tissues in cases of so-called "interstitial nephritis." It is satisfactory to me to find so able and industrious an observer as Dr. Waller amongst the numerous pathologists who, whilst differing as to the explanation of the phenomenon, admit the fact of a genuine muscular hypertrophy in this class of cases. Dr. Waller goes on to express his dissent from my statement that in the hypertrophied renal arterioles there is an inner longitudinal as well as an outer circular layer of muscular fibres. If he will do me the favour to refer to a paper of mine published in the *British Medical Journal* of May 25th, 1878, he will find that I no longer maintain that the inner longitudinal layer of fibres is muscular. The following is an extract from the paper referred to:—"All the characteristic specimens of renal arterioles in the form of disease under consideration (the small red granular kidney) show an inner longitudinal and an outer circular layer of fibres of nearly equal thickness. I formerly supposed that the inner longitudinal as well as the outer circular layer was muscular; but I am now convinced that the inner is the thickened elastic coat; and since this thickened inner layer has precisely the same structural appearance and arrangement as the elastic layer in the larger, but still microscopic, arteries, I cannot but look upon it as being thickened by a true hypertrophy or overgrowth of the normal tissue. And a probable explanation of the hypertrophy of the elastic inner tissue of the arterioles is to be found in the need for resisting the tendency to elongation of the arterioles by the injecting force of the hypertrophied left ventricle. The tortuosity of many of the hypertrophied renal arterioles shows that they have become more or less elongated by the injecting force of the heart, notwithstanding the increased thickness and strength of their longitudinal elastic tissue; and it can scarcely be doubted that, but for the strengthening of the elastic coat by this hypertrophic thickening, the elongation and tortuosity of the arterioles would be much greater than they are."

The thickening of the tunica intima in the hypertrophied renal arterioles is so constant and so uniform in its structural characters—in this respect differing entirely from syphilitic or tuberculous, or other undoubted pathological thickenings—and, as a rule, it bears so constant a relation to the hypertrophy of the muscular coat, that I cannot but look upon both as examples of a true physiological hypertrophy, as distinguished from an inflammatory or other pathological thickening. Dr. Waller, while admitting the anatomical fact of hypertrophy of the muscular walls of the arterioles, doubts my physiological explanation of the phenomenon, but has "no feasible exegesis of his own to offer." His explanation of the cardiac hypertrophy associated with advanced granular kidney is that it is a result of obstruction caused by "obliterative thickening of the tunica intima" of the systemic arterioles. With regard to this theory, I would remark that it affords no explanation of what Dr. Waller admits to be the "inconvenient" fact of the muscular hypertrophy in the walls of the arterioles. And it also takes no account of the undoubted fact that in cases of acute renal disease, with uræmia, there is evidence of high arterial tension with increased cardiac action, phenomena which entirely pass away with the cessation of the renal disease. These facts admit of a complete physiological explanation by the theory of temporary over-action of the muscular arterioles ("arterial stopcocks"), excited through the vasomotor nerves by the influence of the morbid blood, as in chronic cases the continued over-action of the same arterioles results in hypertrophy of their walls and correlated hypertrophy of the left ventricle of the heart.

Savile-row, W.

OBSERVATIONS IN URINARY PATHOLOGY AND THERAPEUTICS.

By C. H. RALFE, M.D. Cantab., F.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL.

(Continued from p. 129, vol. ii., 1880.)

III. CASES OF DIABETES INSIPIDUS CHARACTERISED BY AN EXCESSIVE ELIMINATION OF PHOSPHORIC ACID (THE SO-CALLED PHOSPHATIC DIABETES).

Under the terms Diuresis, Diabetes insipidus, Polyuria, and Polydipsia, writers have described a certain morbid condition of the system characterised by the excessive and persistent discharge of urine of low specific gravity—containing, however, neither sugar nor albumen. Most authors apply either of the above terms to denote this urinary superflux, without reference to the quantitative relationship that may exist in individual cases between the urinary water and solids. Others, of whom Willis[1] seems to have been the first, have attempted to form a classification on this basis. Thus Willis divided cases of diabetes insipidus into three groups: (1) those attended with excessive discharge of aqueous urine, in which the solid matters are deficient—*hydruria;* (2) those attended with a copious discharge of urine characterised by a deficiency of urea—*anazoturia;* and (3) those in which the excessive discharge of urine was attended with a superabundance of urea—*azoturia.* Parkes[2] also supported the view that diabetes insipidus was to be found existing under three different conditions—(1) In cases where there is no increase or decrease of tissue metamorphosis; (2) in cases where there is a decided decrease of tissue metamorphosis; (3) cases where there is evidence of increased tissue metamorphosis as shown by the increase of some of the urinary solids. To this latter class of cases Professor Parkes thinks the term polyuria preferable to that of azoturia, which only expresses the fact of the urea being increased; whereas in the cases quoted by him the fixed salts, as chlorides, sulphates, and phosphates, were also present in abnormal quantities. Lately Dr. Tessier[3] of Lyons has recorded a series of cases closely resembling saccharine diabetes, in the increased discharge of urine, the thirst, the neuralgic and rheumatic pains, the wasting, and the secondary lung complications, only that no trace of sugar could be found in the urine, and that the constant phenomenon was a very considerable increase in the quantity of phosphoric acid excreted (fifteen to twenty grammes of earthy phosphates in twenty-four hours). In some of Dr. Tessier's cases the urea was also eliminated in excess, but not in all, a fact which Dr. Tessier thinks serves to distinguish them from the cases originally described as "azoturia." Dr. Tessier has given the name "phosphatic diabetes" to this class of cases. He divides them into four groups—1. Those in which nervous symptoms are predominant. 2. Those which accompany pulmonary consumption. 3. Those which alternate with or co-exist with saccharine diabetes. 4. Those which run a distinct course resembling saccharine diabetes, but without sugar. As a few cases resembling in many respects those described by Dr. Tessier have come under my observation, although in none of them were the symptoms so marked or the excretion of phosphoric acid so considerable as in those described by him, I venture to think a brief account of them may be of some service in illustrating this interesting and obscure point in urinary pathology.

Case 1. *Polyuria with increased excretion of phosphoric acid and urea; nervous symptoms.*—J. H——, aged sixteen, was admitted into the Seamen's Hospital July, 1876, in a stupid, semi-comatose condition, extremely feeble, and emaciated. Weight under 9 st.; no great thirst; passing large quantities of urine of medium specific gravity, with trace of albumen; no sugar. No history of syphilis or injury to head. Analysis of the twenty-four hours' urine gave the following result:—

Quantity	2900 cc.	
Specific gravity	1010	
Earths } (phosphoric acid)	2·3 }	5·2 grammes.
Alkalies }	2·9 }	
Urea	51· grammes.	

The lad remained in bed for several days in a dull, stupid condition, and then gradually brightened. The diuresis continued excessive during the whole period of his stay in hospital, the specific gravity ranging from 1010 to 1015. He was treated successively with large doses of valerian, with small doses of opium, with cod-liver oil and quinine. He improved greatly under treatment with regard to his general condition, but he was still polyuric when discharged. In this case the quantity of urine passed was about three times, the solids about double (calculated from the specific gravity), the phosphoric acid more than treble, and the urea rather more than double the normal for a lad of his age. In this case there was a decided increase of tissue metamorphosis, as evidenced by excessive excretion of urea and phosphoric acid, the latter especially. It comes under Dr. Parkes's third definition, and corresponds with the first group of Dr. Tessier.

Case 2. *Polyuria; increased elimination of phosphoric acid; death; small syphilitic gumma at base of brain.*—T. G——, aged twenty-four, a patient of the late Dr. Murchison, came under my observation on August 24th, 1878, during Dr. Murchison's absence from town. The patient, a slight man weighing about 9 st., had been ailing four or five months; sight failing for a month, but has got rapidly worse during the last week; cannot now read or count fingers when held up. Passing large quantities of water; syphilis five years ago. Ophthalmoscopic examination only revealed slight fulness of veins. He was instructed to collect and measure urine, and bring some for analysis next visit.—August 28th: Patient much worse; complains of violent pain in head. Quantity of urine passed in the last twenty-four hours 9500 cc.; reaction neutral; sp. gr. 1004; phosphoric acid 6 grammes.—August 30th: Violent pain in head; now quite blind; as he required more care and attention than he could in his circumstances receive at home he was taken to St. Thomas's Hospital. Here, shortly after his admission, he became delirious, and then comatose, and died on September 2nd. I am indebted to the courtesy of the then house-physician for a note with regard to the condition of the brain, as found at the post-mortem examination: "A small syphilitic gumma, about half the size of a small hazel-nut, situate in the middle line under the floor of the third ventricle, obstructing some of the vessels at the base; some softening of the brain substance."[4]

Case 3.—*Polyuria moderate; increased elimination of phosphoric acid; hypochondriasis; rheumatic pains in loins; emaciation.*—Out-patient, under my care at the London Hospital. First seen September 16th, 1880. A small but well-built man, aged twenty-five, weighing about 9 st., employed on the East London Railway; attributes his illness to over-work. No history of syphilis. Temperate habits. Has a pale, anxious, haggard expression. States that he has been ailing some months, has lost flesh, and complains of a feeling of extreme nervousness and exhaustion, with frequent fits of trembling. Constant tearing pains in loins; often shooting round the pelvic region, with cramp-like spasms in lower parts of abdomen. No lightning pains, patellar-reflex unimpaired. Vision perfectly distinct. No apparent disease of abdominal or thoracic viscera. Digestion fairly good; bowels constipated. Urine pale, whey-like, of medium specific quantity; alkaline reaction; no sugar; no albumen. States that he passes more urine than he should, and is frequently disturbed at night to pass it. Instructed how to collect and measure it, and to bring a sample of the mixed twenty-four hours' urine at the next visit. The patient, however, did not comply with all the conditions necessary for accurate measurement, and it was not till Oct. 21st that I was satisfied that my instructions had been carefully carried out. By that time he had been five weeks under treatment (mineral acids and nux vomica), and had improved to some extent. Analysis of twenty-four hours' urine.—Oct. 21st: Quantity 2300 cc.; sp. gr. 1015; reaction alkaline. Phosphoric acid 5·8 grms., or nearly treble what it should be for a man of his weight. Ordered codeia pill, one-third of grain, and a mixture with bromide of potassium and nux vomica.—Nov. 18th: Very much improved; is gaining weight, feels stronger, has nearly lost the pains, discharge of urine still more abundant than it should be. To collect and measure it as before and bring a sample at next visit. To continue mixtures but to discontinue the codeia.—Nov. 25th: Analysis of urine: quantity 2300; sp. gr. 1015; reaction alkaline. Phosphoric acid 5·8 grms.; urea 33·5 grms.

---

[2] Ed. Parkes, M.D., F.R.S.: The Composition of the Urine in Health and Disease.

[3] L. J. Tessier: Du Diabète Phosphatique. Paris: Baillière et Fils. 1877.

[4] This case was plainly one of hydruria, or diabetes insipidus, without increased tissue metamorphosis, the diuresis being a consequence of the cerebral lesion. The increase of the phosphoric acid (nearly treble the normal) is, I think, sufficiently accounted for by the large quantities of milk and beef-tea taken to quench thirst at that period of the illness when the analysis was made, and also to some extent to the washing out of the tissues by the drainage going on through the body.

CASE 4. *Excessive elimination of phosphoric acid; no polyuria; hypochondriasis; enormous quantities of calcium oxalate in urine.*—A gentleman's servant, aged twenty-seven. First came under observation September 28th, 1880. He is a thin spare man, weighing about eight and a half stone; of sallow, haggard complexion. No history of syphilis; habits temperate. Complains of aching pains, especially in the loins, shooting down the hips, and occasionally affecting the bladder and testicles. Alleged loss of virile power. Abdominal and thoracic organs apparently healthy. Digestion fair, bowels constipated. Feels very wretched and depressed. Urine passed at the time of visit (11 A.M.) acid; specific gravity 1028, containing eight grms. of phosphoric acid in 1000 cc. The secretion of urine, he said, was not excessive; he was rarely troubled during the day, but frequently at night with calls to micturate. (He was requested to collect and measure the urine for a few days, and send a note with regard to the quantity passed in the twenty-four hours; this proved to be just under two pints, or about 1100 cc.) The urine he passed in my presence deposited in a few hours an enormous quantity of oxalate of lime; no sugar; no albumen. Ordered codeia pill, a quarter of a grain, at night, and a mixture of hydrochloric acid in nux vomica and cod-liver oil.—Nov. 18th: Is much better. Less pain in loins. Not so despondent, though still fears he is impotent; confesses, however, to occasional manifestations of "his nature." To discontinue codeia and take phosphorus pills, one-sixtieth of a grain, instead. To collect urine for twenty-four hours and send it for examination.—Dec. 1st: Quantity 1520 cc.; sp. gr. 1022; urea 41·2 grms.; phosphoric acid 5·2 grms. Still under observation.

CASE 5. *Polyuria; increased elimination of phosphoric acid, co-existing with a mild form of glycosuria.*—A gentleman aged thirty-seven, who for the last eighteen months has suffered intermittently from a mild form of glycosuria, which did not apparently affect his general health, began in the autumn of the present year (1880) to suffer from constant aching, boring pains in the loins, shooting round the pelvic regions, with occasional cramp-like sensations in the bladder, and a tired, sore feeling in the muscles of the thighs and calves of the legs. He also became dispirited and hypochondriacal; began to lose weight and flesh. The amount of sugar passed had never been excessive, and had always been controlled by restricted diet. At this time he was certainly not passing more sugar than he had done in the earlier stage of his illness, and it again disappeared when he placed himself on restricted diet for a few days. Still, however, the pains and malaise continued.

On Oct. 12th the urine was collected for twenty-four hours, and subsequently on Oct. 14th and 15th, and Nov. 3rd, 21st, and 26th. On each occasion the amount of phosphoric acid present was estimated with the following results:

	Quantity.	Sp. gr.	Phosphoric acid.	Sugar.	Urea.
Oct. 12th	2020 cc.	1018	7·6 grms.	nil.	—
,, 14th	2300 cc.	1015	6·9 ,,	nil.	—
,, 15th	1520 cc.	1020	5·7 ,,	nil.	—
Nov. 3rd	2500 cc.	1012	7·5 ,,	considerable	—
,, 21st	2350 cc.	1019	8·2 ,,	,,	—
,, 26th	2300 cc.	1018	4·6* ,,	,,	69 grms.

* Phosphoric acid in combination with the earths, 2·1 grms.; with the alkalies, 2·5 grms.

The patient began taking codeia in half-grain doses at bedtime on the night of Oct. 12th, and continued to take it till Oct. 25th; it was then discontinued, as he was feeling better. On Nov. 3rd the pains, however, returned with considerable severity, and the codeia was resumed, but it was only taken occasionally up to Nov. 20th. Sugar also reappeared in the urine in more considerable amount than had been previously noted and continued till the patient left town. No special reason could be assigned for the reappearance of the sugar, as the diet was in no way different on the days of its reappearance than it had been during the period immediately preceding. That is to say, the diet had been restricted, with the exception of a small quantity of crust of bread taken with each meal. Grain doses of extract of opium were now given at bedtime till Dec. 4th, when the patient left town for a month's rest. During that time he took no medicine. Most of the holiday was spent at watering-places, where he bathed daily and made use of tepid saline douches; he also took a considerable amount of walking exercise. He returned to town, feeling better in every respect. He has regained his lost weight, and is now bright, cheerful, and hopeful. The pains in the loins and thighs still, however, trouble him occasionally. The urine (January 15th) on examination gave the following result. Quantity 1900 cc.; sp. gr. 1020; urea 66 grms.; phosphoric acid 3·8 grms.; no sugar.

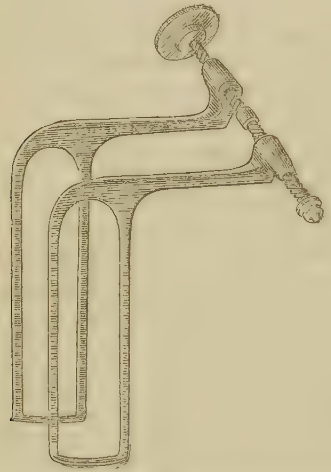
(To be concluded.)

THE
MECHANICAL TREATMENT OF CROUPOUS MEMBRANE AFTER TRACHEOTOMY.

BY C. H. GOLDING-BIRD, M.B., F.R.C.S.,
ASSISTANT SURGEON TO GUY'S HOSPITAL.

IN membranous laryngitis, after tracheotomy has been performed, the case resolves itself, as far as the surgeon is concerned, almost entirely into one of foreign body in the trachea and bronchi, that is if the membrane has already reached so far down; if not, then the dyspnœa will be for the time quite relieved by the operation, but in due course the disease having reached the lower parts of the windpipe, symptoms of a foreign body obstructing respiration again appear. The remarks now made and the cases quoted are in illustration of a method of dealing with such a condition as that last named. Usually on the opening of the trachea a suitable silver tube is at once inserted, as much with the idea of stopping blood getting into the trachea as of relieving the dyspnœa. For some time after the child coughs up clots and blood-stained mucus, with perhaps some membrane, while the greatest anxiety is felt lest the tube should become blocked, and very careful cleansing by feathers, &c., has consequently to be carried out at very frequent intervals; and the patient often does not even then breathe satisfactorily. Such a mode of procedure is *mechanically* wrong, to say the least of it. Everything save air and a minute amount of mucus in the windpipe is a foreign body; and such are the blood and mucus, as well as the membrane, in every croup case. These can scarcely be expelled *viâ* the glottis, for that is already blocked by membrane, while the chances of their finding their way out through a lateral, rigid, and bent tube, the end of which hangs freely in the trachea, like the stem of a funnel in a wide-mouthed bottle, are very remote. If the tracheotomy tube were of the same calibre as the trachea itself, expectoration would be more easy; but it is not only smaller of necessity, but hangs (or should hang) freely in the lumen of the trachea, and with some degree of mobility. That blood and mucus—let alone the more solid membrane—will be readily forced by natural efforts exactly through the mouth of this tube is unlikely, clinical experience shows; and then these foreign matters collect around or below the tube and are sucked backwards and forwards for long before they hit the right path; while the futile efforts of a piece of membrane to make its exit is announced by a valve-like flapping noise, familiar to all who have had much to do with tracheotomy in croup.

Until therefore the trachea has been cleansed as far as possible from all foreign bodies, the tracheotomy-tube should not be inserted, but other means should be adopted to keep the tracheal wound patent. In eight cases during the last nine months I have acted upon this rule, employing at first the ordinary German nose speculum, as doubtless others have done, instead of a tracheotomy tube, the blades of the instrument being inserted into the tracheal wound, and then screwed open. Although fairly self-retaining, there were many reasons against its being perfect for the purpose, and so the tracheal dilator here figured has been designed. It is inserted, with the blades screwed together, into the trachea, the handle lying against the top of the sternum; on rapidly turning the screw the blades separate to the required extent, and their shape renders them self-retaining. If desired, tapes can be tied to the blades where they join their handles, and fastened round the neck, but this is not often requisite. The blades retain their parallelism even when fully open, as they do not work from a hinge, but travel along the double screw. This improvement of the screw over the hinge (which I first employed) was suggested to me by Mr. Lund of Manchester. The same sized dilator does for all cases, whether infants or adults. In any case it may take the place of a tracheotomy tube on an emergency, even when no foreign body has to be extracted. After tracheotomy in every case of membranous laryngitis two distinct mechanical problems are presented to the surgeon:—(1) The establishment of a free passage through which membrane, &c. may be expelled by natural efforts; or, this failing, (2) its removal by artificial means. In either case, as a preliminary, a sufficiently free opening into the trachea must be made—five-eighths of an inch even in infants, and proportionately longer in older persons. This done, the following steps fulfil as nearly as possible the above requirements :—



This instrument, as well as the brushes on steel wire, are made by Millikin and Down, St. Thomas's-street, S.E.

(*a*) At once insert (with the left hand) into the tracheal wound the blades of a pair of dressing forceps, and then open them as widely as possible. Free expectoration of blood, mucus (and perhaps membrane) will follow, and these can be rapidly sponged from the lips of the wound. A clear passage being thus insured, expectoration and coughing are rapidly over and full inspiration restored, while all blood is brought up from the air passages within a few minutes.

(*b*) To determine the presence of membrane in the trachea (i. e., below the glottis) reflect a strong light into the wound from a mirror on the operator's forehead. If there is no membrane, the posterior wall of the trachea may be seen, pink and moist, and looking very much like the outer wall of the œsophagus. Small pieces of sponge held in dressing forceps can be used to clean it from bubbles of mucus. If healthy it may be taken for granted that there is no membrane below—the formation of membrane proceeding from above downwards. If an inspection be now made in an upward direction through the wound, membrane will perhaps be seen just entering the trachea from the larynx. The operator is at present below the obstruction.

(*c*) To maintain the tracheal opening patent, a tracheotomy tube can be now inserted, until evidence of membrane in the trachea is forthcoming; but supposing this stage now reached, or to have existed at the time of the operation, a tube is best dispensed with. Instead of dressing forceps or tube, insert the tracheal dilator into the trachea itself, not only into superficial tissues, and dilate until it holds firmly; the least possible opposition is thus offered to natural expulsive efforts. An inspection of the trachea will now show either a layer of characteristic membrane or else the mucous surface will have lost its pink colour, be cloudy and white; when this is seen it may be taken as a sure sign of coming membrane. In cases where the membrane has been stripped off and the normal appearance as far as possible restored, this white cloudiness will be always a sure precursor of a fresh formation.

(*d*) To remove membrane if seen. If natural efforts have failed the surgeon should (lighted still by the mirror on forehead) remove with forceps (for example, aural polypus forceps) all that can be seen, or that is coughed up to the opening. Membrane may be now searched for below the wound. Minute pieces of sponge held in curved forceps, or feathers, can be passed down; but I prefer for this purpose a brush, like a rather large pipe cleaner, on strong but flexible steel wire. I at first used Maw's feeding-bottle brushes, but they are very liable to break, and therefore had the stronger ones made. Before use they should be put into hot water. They may be passed in a child three inches from the wound—that is, well into the first division of the bronchi, and if rotated sharply at the moment of retraction will detach and draw up often large pieces of membrane. When mucus rather than membrane obstructs, feathers and minute sponges are preferable. If the air passages are thus rendered free, the patient can be left again to the nurse with instructions to mop out frequently with small pieces of sponge, held in artery forceps, anything coughed up to the wound; and also, by reflected light, to pick out any visible pieces of membrane. At the same time the usual adjuncts of alkaline and other sprays should be employed. Hot flannels can be placed over the dilator. There is less anxiety to the surgeon now, for there is no tube to get blocked or to be cleaned by the nurse; for the dilator need never be touched even for days, and as the wound granulates it is imbedded and held more and more firmly. It is perfectly comfortable, and seems to give no pain; it causes no irritation, and except in one case, not under my care, where a small abrasion was seen after death of the mucous membrane of the trachea, it has left no mark of its presence. Automatic retractors for the soft parts, during the operation, are recommended by some; but to urge the systematic employment of tracheal dilatation instead of a tracheotomy tube, as long as any foreign body, of whatever kind, has to be got rid of, is the object of this communication.

While the chances of death from suffocation are by this means, I believe, much diminished, the use of the dilator does not seem to influence one way or the other the onset of pneumonia or pleurisy—the usually fatal terminations to croup. Of the eight cases already referred to, four died of pleurisy or pneumonia, two recovered, and two died with suffocative symptoms. Of these, one a girl aged two years and a half, showed on inspection the smaller tubes blocked with membrane, but the trachea and bronchi were quite free, having been cleansed during life and there having been no reformation of the membrane; the other, a boy aged five years, had had the upper air passages cleared of large casts on several occasions, the child each time being completely relieved of all symptoms; at last, however, all efforts to sponge or brush up membrane failed and the child died asphyxiated, the inspection showing a peculiarly adherent membrane in the trachea that required some force to tear off with forceps, while the tubes, both large and small, were lined with membrane of ordinary character and appearance.

The case appended illustrates the points above mentioned. A fatal case is taken that the post-mortem appearances may be noted. The only remarks on cases of recovery would be that the expectoration of membrane gradually gave place to one of muco-pus, and that in its turn to one of simple mucus; between these two last stages the dilator is removed for good.

CASE.—Julia W——, three years and a half old. First seen at 8 A.M. on Dec. 26th, 1880. Symptoms of dyspnœa for two or three days; now struggling for breath, and semi-cyanotic. Frothy expectoration. The child's general health, apart from its present attack, not good. Tracheotomy at once without an anæsthetic, and dressing forceps inserted into the wound and opened; blood and mucus freely expectorated. Two more rings now cut, and by reflected light a complete cast of the trachea seen, and removed with forceps. A few shreds of membrane were also brought up from below the wound with a feather and brush. Forceps now withdrawn, and tracheal dilator inserted, and the patient returned to her cot breathing comfortably. At

11 A.M. frothy mucus in the trachea was removed with a feather, and the nurse was provided with artery forceps to hold minute pieces of sponge, or to remove membrane, if any seen. At 6 P.M. the nurse reported membrane brought up on feather; so by reflected light the trachea was again examined, and much membrane removed with a feather and brush; some was coughed into view, and removed with forceps. Child was left breathing comfortably. Ordered carbonate of soda (three grains to one fluid ounce) as spray to trachea twice every hour, or whenever breathing became difficult. At 10 P.M. the child expectorated through the wound much muco-pus. On Dec. 27th, at 9 A.M., the same report; large tubes seem clear. At 4 P.M. the respiration was very rapid, and symptoms of pneumonia had developed since the morning, and at 7 A.M. on Dec. 28th the child died. Throughout the child had been in a tent, with steam, and had worn the dilator.

Post-mortem examination. — Basic pneumonia; membrane in all the smaller tubes; there was none in the trachea or larger bronchi; there was no mark to show where the dilator had been worn.

St. Thomas's-street, S.E.

ON THE

ANTIPYRETIC TREATMENT OF TYPHOID FEVER BY MEANS OF SODIUM SALICYLATE.

By HENRY TOMKINS, M.D.,
MEDICAL OFFICER TO THE MONSALL FEVER HOSPITAL, MANCHESTER.

THE subject of the treatment of typhoid fever will doubtless by many be considered as one that has been threshed out over and over again without yielding results at all commensurate with the time and labour bestowed upon it; and perchance there are but few who have not come to the conclusion that whatever be the treatment adopted in this disease, whether most active or most passive, the general results obtained will be of very little practical difference. But whilst we have year by year a death-roll facing us of nearly 10,000 souls of every rank and condition of life, in this country alone, but little apology is needed for again bringing forward any treatment that offers a probable reduction in the above mortality.

At the present time the lines upon which our treatment of typhoid is laid down may be broadly stated as two—viz., the expectant or non-therapeutic, and the specific or active treatment, this latter having taken the form of a vigorous attack upon the pyrexia of the disease, which is looked upon, and justly so, as one of, if not the most important of all its attendant phenomena. For at the present day no man having any pretension to a rational knowledge of medicine would any more dream of conducting a case of typhoid fever without the constant use of his thermometer, than he would of diagnosing a lung affection without his stethoscope.

It has been truly said that 80 per cent. of all these cases need no medicinal treatment. In a sense this is true; but what about the remaining 20? For the former the "expectant" treatment is sufficient, but when we have to deal with the more severe minority, how helpless do we feel when we see the patient slowly drifting beyond the borderline of safety, the temperature steadily rising and maintaining a degree which, as we know all too well, cannot long be borne by the system without speedily inducing a fatal termination.

If, as is now generally held, all the so-called "zymotics" depend, as we have positive evidence some do, upon the presence within the body of a specific living poison, a true contagium vivum, having properties as distinct and powers of reproduction of its kind as perfect as any genera or species known to botanist or zoologist, then surely it is not an idea so very chimerical that we may have a specific remedy or antidote for each of these living toxic agents; and although I have no evidence to bring forward that sodium salicylate is a specific remedy, still we know that our most powerful agents for reducing the body heat are also powerful germicides and preventives of fermentation, quinine standing high on the list, and salicylate of soda still higher, 1 part in 20,000 of the latter sufficing to perfectly preserve saccharine fluids from fermentation, and to arrest the action of myrosin in mustard and other well-known fermentation processes. On this point also may be cited an experiment made last summer with the saliva of a rabid dog. Two others were inoculated from it, the one with saliva pure from the rabid animal, the other with the same to which 1000th part of salicylate was added. The former developed all the symptoms of a severe attack of rabies, and died on the thirteenth day; the other is still alive and well. And could we isolate the typhoid poison, or cultivate it apart from the body, as with some infective organisms, sodium salicylate would possibly prove a certain destroyer of that poison also. Therefore I would suggest only as a *possible* theory, as we know so little how it acts, that the antipyretic powers of this agent may be due to its power as a germicide; the more so as these properties are very much less seen in febrile action due to local inflammations, as pneumonia or pleurisy, than in those where we have ground for supposing some poisonous principle is circulating in the blood. But putting all theory aside and keeping solely to facts, and using it simply as a remedy for the treatment of a symptom in the typhoid process, the same as we would use styptics for hæmorrhage, alcohol for failing circulation, or sedatives for delirium, we have in it a means, and a most powerful one, of controlling the much-dreaded increased temperature of the body. And here we may briefly consider upon what rational grounds the employment of any antipyretic treatment is *à priori* to be advocated. In typhoid fever we have a disease for which we have no specific remedy that will abort or cut short its career, and all that lies within our power is to treat symptoms as they arise. Amongst its more dangerous manifestations is that of a long-sustained high temperature, which not unfrequently becomes the most important factor in our diagnosis, prognosis, and treatment. In the greater number of fatal cases (setting aside those due directly to hæmorrhage and perforation) the patients appear to succumb to the direct effects of the excessive febrile movement; and therefore, if we can with certainty guard against the deleterious influence of this pyrexia, we shall rob the disease of a great part of its terrors. It is undisputed that the rapid degenerative changes found throughout the body, in muscle, glands, and viscera, are due directly to the increased temperature, these changes being found in proportion to the height and duration of the pyrexia; but of even greater importance is the deleterious effect produced upon the heart, and through it upon the circulation and upon the central nervous system. This being so, surely any agent that offers itself as an available weapon with which to combat, if not the specific poison, yet one of its most serious manifestations, is deserving of a fair trial before it is declared to be found wanting.

Does therefore salicylate of soda offer any, and if so, what, advantages over the means more commonly used to reduce this temperature? Foremost stands at present the cold bath. Many and enthusiastic, especially on the Continent, have been the advocates of this method, but I make bold to say that in the typhoid of this country at least it is not a remedy upon which we can always rely, neither is it always safe; and, chief point of all, it is not capable, and never will be, of daily ordinary application. And as much of the treatment of typhoid is not conducted in hospital, but by the usual medical attendant, it practically is not possible, to say nothing of the prejudice of the patients' friends, to carry out this treatment in the manner that its advocates demand.

Again, even its most ardent supporters, such as Leibermeister of Tübingen, admit that it is not admissible in all cases, as it is apt where there is a high degree of cardiac weakness to induce fatal collapse. And the same authority says that, if he were restricted to the sole use of either the cold bath or quinine, of the two he would prefer the latter.[1] Quinine without doubt has large powers as an antipyretic, but the doses necessary for the full production of its effects are taken by patients with extreme loathing, and are exceedingly apt to produce nausea, vomiting, and serious disturbance of the stomach, to say nothing of the practical objection to its extensive use from its present high commercial value.

That sodium salicylate is a powerful agent, and one requiring skill and care in its administration, is at once admitted; its physiological effects are powerful and well marked. When given in full doses certain well-marked phenomena are observed—deafness, noise and ringing in the ears, a certain amount of restlessness, copious and rapid excretion by the kidneys, with usually a small amount of albumen in the urine. It is to be noted that no effect, or at most a very slight lowering, is produced upon a normal temperature, but very different is the case when we are dealing with a supra-normal temperature.

---

[1] Vide Ziemssen's Encyclopædia, article Typhoid, p. 216.

Although it is now matter of common experience that in the salicylates we possess the most powerful antipyretics to be found in the whole range of our therapeutic armamenta, yet it would appear that in this country at least these properties have in the treatment of typhoid been but little made use of. Even recently in the masterly address given by Sir W. Jenner on the treatment of this disease, alluding to salicylate of soda, he dismissed it with the remark, "it is said to reduce the temperature." In Germany it has been used, but chiefly in conjunction with other remedies, as quinine, digitalis, and concurrently with the use of the cold bath; and lately in France Dr. Hallopeau has given to the Société Médicale des Hôpitaux a favourable report of the results obtained by its use in a small number of cases treated by him solely with this remedy.[2] The number that I have treated with salicylate up to June, 1880, is forty-six, twenty-eight males and eighteen females, varying in age from seven to fifty-six years, the larger proportion being between fourteen years and thirty-five. They represent only the more serious cases received into this hospital, and are about one-third of the whole number admitted during the time over which the treatment extends. In no case was the soda given when the temperature in the axilla was below 102°. The general treatment, in addition to the special, may be summed up thus: perfect rest, milk diet, with small quantities of beef-tea, acid and opium when diarrhœa excessive, acetate of lead or turpentine, with iced injections, for hæmorrhage. Alcohol was never given unless the state of the circulation decidedly demanded it, except in the convalescent stages of some few cases in the form of wine. It should be noted that in the whole of these the temperature was taken every two or every three hours, night and day, whilst the salicylate treatment was being pursued, so that its effect hour by hour could be distinctly watched.

The routine practice has been this:—As soon as it was certain that there was a continuous temperature of more than 102° in the axilla, fifteen to twenty grains of the soda were given every two hours. This after about six doses usually reduced the temperature two to three degrees; if not, the same dose was continued a few more hours until it had done so, this seldom exceeding twenty-four hours from the commencement. The dose was then diminished one-half, and given every two or three hours, increasing it through the day if there was much tendency to exacerbation towards night-time. This was carried on for a period varying from three or four to nine or ten days, seldom exceeding the latter time, when the temperature would usually be fairly normal, with a little inclination to an evening rise in many cases for a few days after the salicylate was entirely discontinued. In most of the cases the usual physiological effects were observed, and in several alcohol was freely administered with the soda, in the form of brandy, whenever the pulse was feeble or the weakened action of the heart appeared to be becoming dangerous. *(To be concluded.)*

Cork Fever Hospital.—During last year 784 patients were under treatment, being an increase of 284, when compared with the number admitted in 1879. This increase was mainly due to the great prevalence of typhus, scarlatina, and typhoid fever. The mortality in the typhus patients amounted to fourteen per cent., which, deducting seven cases admitted in a hopeless condition, represents a mortality of only eleven per cent. The cases of scarlatina were mostly of a malignant type—the mortality being seven per cent. Cork was exempt from small-pox, which had prevailed in Dublin and other cities. An instance is given in the report in which a "wake" was held lately upon a person who died from typhus, and six cases were subsequently admitted to hospital who had attended that "wake." Since the year 1802, up to 1880, 114,213 persons were treated at this hospital, with a mortality of 6250, including 925 from Asiatic cholera, which averaged fifty per cent., and 150 from small-pox, with an average of twenty-two per cent., the total deaths from fever being but five and a half per cent.

A CASE IN WHICH THE MASTOID WAS PERFORATED FOR SUPPURATION, WITH SATISFACTORY RESULT.[1]

By SIMEON SNELL, L.R.C.P. Lond., &c.,
OPHTHALMIC SURGEON TO THE SHEFFIELD GENERAL INFIRMARY, AND TO THE SCHOOL FOR THE BLIND.

On the 25th of June, 1879, I was asked to see in consultation with a medical friend the subject of the following remarks, and he has kindly furnished me with his notes.

The patient was a man aged about forty, and he had always enjoyed good health until April 21st, 1879, when he suffered from rheumatism or rheumatic gout in the left knee. About three weeks subsequently he experienced for the first time pains in the right ear, though he thinks he must have noticed that his hearing on this side was defective for some short period previously. The pain increased, and he tried a week at Matlock to see, as he expressed it, what change of air and scenery and absence from his employment would do for its relief. Still, however, becoming worse, in the early part of June (9th) he placed himself under the care of his medical attendant. The pain then appears to have been very severe, and of a neuralgic character, behind the ear, and extending over the side of the head and far down the neck. Chloral hydrate and bromide of potassium in combination afforded only temporary relief. By the 21st the intensity of his suffering had increased, the pain being particularly severe over the mastoid region, and, becoming worse at night, rendered sleep impossible. The treatment consisted in emollient and sedative applications to the painful part, and subsequently a blister was applied over the mastoid region. The mixture of chloral hydrate and bromide of potassium in increased doses was continued. Still, however, his condition became worse, the pain progressed in severity, and the paroxysms were getting now very intense, especially at night, and he suffered at times from delirium. Suppuration in the mastoid cells was suspected, and I was requested to see the patient, which I accordingly did.

On June 25th I found his condition to be as follows:—The pain he complained of was of a most violent and excruciating character, worse at some times than at others, and particularly so at night. It was chiefly situated over the mastoid region, but extended above over the head and below in the neck. He had had no sleep for several nights. There was also great swelling and puffiness over the mastoid, and the browniness extended far down into the neck and up along the side of the head. There was a slight purulent discharge from the ear; this, however, he informed me, was of recent origin. The membrana tympani was perforated, and pus was seen in the tympanum. A watch, audible to the normal ear at about forty-six inches, was heard only on contact ($\frac{0}{46}$). The character of the pain, its situation, and the symptoms generally, led me readily to concur in the accuracy of the opinion already formed. It seemed evident, also, that an attempt, though an ineffectual one, was being made to get rid of the pus in the mastoid cells by its passing through the channel of communication between the cells and the tympanum, and from the latter cavity through the membrana tympani and meatus. The symptoms were, however, urgent, and seemed to demand interference. The propriety, therefore, of cutting through the brawny tissues over the mastoid process, and then opening the cells by a trephine, or otherwise, was discussed. The patient, however, expressed himself as somewhat relieved since the application of the blister the day before, and, in addition, the parts were still so vesicated that we decided to accede to his desire to wait a few days; and in the meantime the treatment suggested consisted of poultices over the affected region, the frequent cleansing the ear with warm water, and the administration of quinine and opiates. The relief he experienced, as was to be expected, if our diagnosis were correct, proved very transitory, and I accordingly saw him again on July 1st. The symptoms were then if anything aggravated, and the swelling over the mastoid was certainly more extensive. We decided to operate immediately. An incision was therefore made in the brawny integument over the mastoid two inches in length, and on cutting through the periosteum a little pus escaped. A stout director was then introduced, and catching in a depression, a little pressure caused the bone to yield, and it was pushed on into the interior of the bone, and the opening enlarged by levering the director about in different directions. Pus now readily escaped, in quantity equal perhaps to half a teaspoonful or more. A poultice was directed to be applied, and care was also ordered to be taken to prevent the too rapid closure of the wound. I did not visit the patient after performing the operation, but heard of his immediate freedom from pain, his speedy convalescence, and of his soon being able to resume his occupation. In the early part of April, 1880, however, an opportunity was afforded me of again seeing him. He was then in perfect health—the perforation in the tympanic membrane was closed, and the hearing on this, the defective side, was much improved, the watch being audible at seventeen inches $= (\frac{17}{46}.)$

[2] Gazette Hebdom, Août 20, 1880

[1] Read before the Leeds and West Riding Medico-Chirurgical Society.

Mastoid suppuration, or the minor affection, periostitis, is more frequently met with in connexion with chronic tympanic disease. In the present instance it assumed a more subacute form, and the patient was probably correct in assigning its cause to a metastasis of his gouty affection. The relation of gout to ear affections is referred to by Hinton, Kramer, and particularly by Harvey. Mastoid disease once set up becomes of serious importance, because, if neglected, septicæmia or pyæmia may prove the result. "An extension of the disease to the brain taking place either through the numerous foramina which transmit branches of the middle meningeal artery, or pus may be carried into the circulation through the mastoid vein which passes to the lateral sinus." Many of us must, however, have seen instances in which nature has herself relieved the disease, the evidence being in the sinuses and scars over the mastoid, especially in children. But the present case is, I believe, of interest and importance as exemplifying the good effects resulting from opening the mastoid when suppuration is diagnosed. It is merely the application of general surgical principles so frequently carried out in other regions.

The operation of trephining the mastoid was introduced two centuries ago. Doubtless it, and other procedures with the same object, are performed now more frequently than the scant reference to the subject in the general surgical works would lead one to suppose. In aural treatises its advantages are recognised, and finds amongst its supporters Hinton, Roosa, Troltsch, &c. Roosa puts it that this sound surgical procedure may be fairly said to be established in practice. Twenty-six out of thirty-four cases he refers to, as recorded by Buck, resulted in recovery.

Speaking also of this operation, Von Troltsch says: "It is now to be included among those operative measures which may be demanded by the 'vital indication,' and just as every conscientious surgeon under definite circumstances will feel himself compelled to open the larynx or to operate for hernia, just so urgent conditions occur when perforation of the mastoid process remains as the only possible means of saving life."

Sheffield.

SACCHARINE URINE IN CHRONIC ECZEMA.

By ROBERT LIVEING, M.D., F.R.C.P.,
PHYSICIAN TO THE DEPARTMENT FOR SKIN DISEASES AT MIDDLESEX HOSPITAL.

DURING several years past I have, as a matter of routine practice, tested the urine of all cases of obstinate eczema that have come under my care for sugar and albumen, and I find the presence of one or both very common. It is, however, the frequent presence of the former in the urine of those suffering from severe, obstinate eczema, to which I desire to call attention, and especially with reference to treatment.

One may say broadly that there are two principal and quite distinct groups of cases in which saccharine urine occurs—(1) we have diabetes in its graver forms, depending on profound nervous lesion; and (2) glycosuria, depending on defective assimilative processes, in which certain functions of the liver are especially at fault. It is only to the latter group that I wish to refer. The glycosuria which is met with in the latter half of life is neither uncommon nor always serious; it is, as I have said, apt to be associated with very irritable and obstinate eczema, and in women the saccharine urine acts in addition as a *local* irritant, and makes the eczema about the pudendum almost intolerable; indeed, excessive and intractable irritation in this region in middle-aged women is very commonly associated with sugar in the urine, and is often incurable as long as much sugar remains.

Now I come to the point to which I wish especially to draw attention, and that is that the eczema and the sugar in the above-named class of cases are mainly due to *over-feeding.* I use the term in its broadest sense, and include quality as well as quantity of food. I frequently meet with cases of intractable eczema pudendi in women past middle life, of sedentary habits, and eating three large meat meals a day, and trying by all means in their power to stimulate their appetite, under the erroneous impression that they are "keeping up their strength." Now, in these and similar cases, medicine and local treatment are almost equally useless, unless there is, at the same time, a thorough reform in the diet. The first point is to deprive the patients of sugar as an article of food, except just enough to make light puddings palatable. The reason for this is that much of the sugar passes the liver unchanged, and is therefore worse than useless as a food. The next point is greatly to reduce the animal food, especially mutton and beef, and to substitute for it simple clear soup, and poultry or fish in moderate quantity once a day. Lastly, the chief part of the daily diet should be made up of light farinaceous and milk food, such as bread, rice, and macaroni. This is, I know, contrary to the view often entertained, that saccharine urine should be treated by an animal diet, and that starch should be as much as possible excluded. Now, whatever good may result from such a diet in some cases, I am quite sure that it does not answer in those to which I refer; on the contrary, exactly the reverse holds, and the old routine practice, except so far as sugar is excluded, is quite wrong. I have seen the sugar disappear from the urine and the eczema depart under a change of diet such as I have above recommended. The truth is that many people at sixty, when the tissue changes are slow, eat as much or more than they did at twenty, when all the processes of change are at the height of their activity; what wonder then that unnatural work is thrown upon the skin, kidneys, and other excreting organs of the body. There is some substantial truth in the saying that small eaters live the longest.

Manchester-square, W.

ON CONGESTIVE DYSMENORRHŒA.

By G. ERNEST HERMAN, M.B. LOND.,
ASSISTANT OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL, PHYSICIAN TO THE ROYAL MATERNITY CHARITY, HONORARY LIBRARIAN TO THE OBSTETRICAL SOCIETY OF LONDON.

(Concluded from p. 329.)

IT seems to me that if we have a menstrual pain which is caused by congestion of otherwise healthy pelvic organs, such congestion being brought about by some trifling and passing cause, this pain may with fair accuracy be called congestive dysmenorrhœa; and we may prefix to it the adjective "primary," to distinguish these cases from those in which the congestion is but secondary to some other morbid condition. I shall not discuss which are the parts most congested, or whether they ought to be called congestive or inflammatory. Of course congestion never arises without a cause; but the cause may be transitory, and the resulting changes of longer duration, so that we may be able to discover the latter only, or the cause may be so insignificant that our modes of investigation cannot detect it.

Supposing that cases of this kind of dysmenorrhœa do exist, can any kind of proof be adduced that congestion is the sole cause of the pain? The only proof that I can imagine is, (1) that no other cause for the pain should be discoverable; and (2) that if the pain be due to hyperæmia, it should be relieved by depletion of the overfilled blood-vessels, and, if no abiding cause for the congestion be present, sufficient local bloodletting should cure the patient. Such cases are met with, and I will instance one.

A. K——, aged forty-four, a canvasser's wife, came to the obstetric out-patient department of the London Hospital on Nov. 13th, 1878. Her complaints were of infrequent, scanty, and painful menstruation, of pain between the periods in the right inguinal region, and of dyspareunia. She stated that she had always lived well, and had tolerably good health. Five years ago she had suffered from a skin disease, which lasted a month. For five years she had been subject to "neuralgia" down the left side of the head. During the last winter she had been troubled with rheumatic pains, but they were not severe enough to lay her up. These were the only illnesses she remembered having had. She had never had any bad sore-throat, loss of hair, or bad eyes, and the skin disease mentioned was only on the trunk, not on the arms or legs. She first menstruated at fifteen, and was regular until her pregnancy, the flow usually lasting seven days, and not being copious. It was attended with a good deal of pain, but not enough to lay her up; she did not remember the character of the pain. She was married at thirty-three; her first child was born twelve months afterwards; the labour was a long one, and the child was stillborn. Her second child was born seven years ago; the labour was a long one, but the child lived. She kept her bed for a fortnight afterwards, and suckled the child fourteen months. Between the two pregnancies she menstruated regularly, the flow being rather less than before marriage, and not accompanied with quite so much pain. She had never been quite well since the last confinement, but had suffered from languor and aching in her limbs. She had been regular since weaning the child, the flow at first returning every three weeks, being scanty, and attended with more pain than formerly. During the last two years the interval had been eight or nine weeks, and the flow only lasted a day or so, but sometimes a slight "show" would appear every day for a month. For the same time she had suffered from dyspareunia. She had also had a "dragging pain," referred to the right inguinal region, which was worse at the menstrual period and on any exertion. This pain was relieved by lying down, and when severe was accompanied with nausea. She also complained that she could not hold her urine long, of pain in the dorsal and sacral regions, and of pain in the calves of the legs on standing. For twelve months her appetite had been poor, she had had pain at the epigastrium after meals, and been annoyed much by flatulence, and her bowels had been confined. There was no pain on defecation. Just before the menstrual period there was usually a slight white discharge. She had suffered from "sick headaches" ever since she was about fourteen, from "fainting fits" since the age of twenty, and from hysterics since about twenty-seven. She had been less subject to the fainting fits and hysterics since her marriage, and all three kinds of seizures—sick headaches, fainting fits, and hysterics—had been better during the last three or four years. She was a well built, well-nourished woman. So far from being anæmic, her complexion and mucous membranes were unusually florid. She showed no signs of having wasted. Nothing abnormal was detected by abdominal palpation; there was no marked tenderness anywhere. On vaginal examination the cervix was found large, and to bimanual manipulation the whole uterus seemed increased in thickness, but its cavity only measured two inches and a half in length. The position of the uterus was normal; its shape was not altered except in the manner mentioned; it was quite movable, and pain was not caused by moving it. There was no swelling, nor any local tenderness, in any other part of the pelvic cavity. There were no signs of disease in any other part of the body except that there was an enlarged and slightly painful gland in the right inguinal region, below Poupart's ligament. She was given an aperient mixture, and at intervals local depletion was effected by scarification of the cervix uteri. The times chosen for doing this were the days on which she stated that her symptoms were worse than usual, which was generally at or near the menstrual period. She was scarified on Nov. 13th, Dec. 4th and 11th, and Jan. 8th, 1879. It is not necessary to describe the progress of the case from week to week, during which the same treatment was steadily followed out, and the only change consisted in a progressive diminution of the symptoms. It will be enough to state that on Jan. 15th she said that she thought herself quite well.

On March 14th she complained that her old pains occasionally returned, although they were not so severe as when she first came to the hospital. She was again scarified. On March 28th she again said that she thought herself quite well.

On April 29th she again came to the hospital, but this was not on account of any return of her uterine symptoms, but because the enlarged femoral gland before mentioned was now suppurating. She was transferred to the care of my colleague, Mr. Adams.

Dec. 7th.—She attended in answer to an inquiry. She said that she had continued well. Menstruation had recurred at intervals of from four to six weeks, the flow lasting four days, and being accompanied with pain, but not with more pain than she was accustomed to have before marriage, and much less than the pain she suffered before coming to the hospital. Until September she had hardly any pain at all.

The distinguishing marks of the form of dysmenorrhœa which this case exhibits are these: There is diminution in the quantity of the menses, without any change in the general condition of the patient, such as usually lessens the amount of the flow. There are many diseases which it is well known lead to scanty menstruation; any kind of wasting disease, or any cause of anæmia may do so. The spammenorrhœa which results from conditions such as these is conservative; is not accompanied with pain, and does not demand special treatment, and it is generally evident from the patient's appearance and condition that there is an adequate cause for it. In the congestive cases, on the contrary, the patient remains florid in the face, her mucous membranes continue highly coloured, and her general appearance is so much that of health that it ought to at once suggest to the observer that the cause of her troubles is probably local and not constitutional. With the decrease in the quantity of the menstrual flow there is increase in the accompanying pain. This pain is not very intense, it is not paroxysmal, although there may be remissions in its severity; it is not definitely localised. It is described as a constant dragging, aching, throbbing, or "gathering" pain, and its seat is vaguely indicated as round the lower part of the back and abdomen and down the thighs. It is relieved, but not completely removed, by lying down. It precedes by a day or more, accompanies, and may last a day or two after, the flow. The patient usually also complains of too frequent desire to make water and of slight pain during micturition. Whether other pains are present or not will depend upon the degree of congestion, and so will the severity of the pain and the length of time it lasts; it may be continuous from one menstruation to the next.

Local examination shows no very striking change in the condition of the pelvic organs. The uterus is quite movable, is natural in shape, but may be slightly enlarged; its canal is pervious. There is no swelling to be felt in either vaginal cul-de-sac. Pain is usually produced by moving the uterus or by compressing it between the hands. These, I believe, are the chief marks of the cases in which congestion is the cause of painful menstruation. Diminution in quantity of flow, with increase of pain, and absence of any condition of the general health which could account for the former, and of any definite local disease which could cause the latter.

In further support of these statements I may cite Aran, who, speaking of congestion of the uterus, says, "Most often the menses become more scanty and more irregular, sometimes altogether wanting at the period, which is yet accompanied by pains which indicate an evident molimen, sometimes appearing at very short intervals, every three weeks, every fortnight, or every week, but consisting in a very small discharge of blood. This diminution in the quantity of menstrual blood is almost characteristic of the dysmenorrhœa which is connected with congestion, or congestive dysmenorrhœa."[1] I have already referred to Dr. West's lectures, in which he states that there are two forms of congestive dysmenorrhœa—one in which menstruation is profuse, another in which it is scanty. He doubtless, in mentioning the latter group, had in mind cases such as those described by Aran. Barnes describes the same thing, but he puts it under the head of "inflammatory dysmenorrhœa." He says, "Inflammatory dysmenorrhœa is not common in single women. The clearest examples are those in which dysmenorrhœa follows on suppressed menstruation, as from the sudden shock of cold, injury, or emotion, sustained during the flow. Under this circumstance, metritis, or at least uterine congestion, is very likely to arise; and an inflamed organ necessarily performs its function, if it be performed, with pain. Not uncommonly, in these cases, pelvic peritonitis and oöphoritis complicate the metritis; and these conditions in themselves will make menstruation painful."[2] Becquerel recognises that there is a form of dysmenorrhœa which is relieved by depletion.[3]

I follow Aran in calling these cases "congestive," because

[2] Diseases of Women, 1st edition, p. 352.

[3] Traité Clinique des Maladies de l'Utérus et de ses Annexes. 1859. Tome ii. p. 393.

I do not see definitely present signs of inflammation. I do not wish to attempt a too exact definition of the pathological nature of the deviation from health which is present; for as the disease is not fatal, we seldom, if ever, can ascertain exactly what changes have taken place. Paget says of congestion: "Herein ...... is one of the pieces of neutral ground between health and disease; a step in the one direction may effect the return to health; in another the transit to what all might admit to be the disease of inflammation."[4] I shall not discuss whether in the cases in question the congestion has or has not made the transit to inflammation. As to the seat of the congestion, the hyperæmia which accompanies natural menstruation affects more or less all the pelvic organs, and therefore I suppose the congestion which causes pain does so too. Signs pointing to an especial affection of one part are in these cases absent.

It is these cases that I think best deserve the name of congestive dysmenorrhœa. It is by the study of uncomplicated cases only that we can hope to ascertain the natural history and clinical features of any form of disease. I do not say that with the various forms of disease which have been set down as causes of congestive dysmenorrhœa, menstrual pain due to congestion does not occur. It would be surprising if it did not, and doubtless it often does. But I do not think it is always the case that the dysmenorrhœa accompanying these conditions is due solely to congestion, or that sufficient criteria have been laid down to enable us to pick out the cases in which the pain is of this kind. Cases of this primary form (so-called "idiopathic," a term which I think objectionable, because implying that the congestion arises without a cause) are not common, and I have not notes of a sufficient number to enable me to draw any conclusions from them as to etiology. I believe that, as Barnes says, it is more common in women who have had children than in virgins, and that it may be produced by cold, or by physical or emotional shock, such as fatigue, fright, anger, &c. The effect of venous congestion from heart, lung, or liver disease, in producing this (as Scanzoni asserts) or other uterine disorders, is in itself a wide subject, which I will forbear discussing here.

The proof of the correctness of the diagnosis in these cases is the success of the treatment. It is commonly the case that in diseases which are not fatal, and in which, therefore, post-mortem verification of our views regarding them is not possible, the effect of treatment is the only test of the accuracy of diagnosis. *Curatio ostendit morbum.*

The effect of treatment in these cases is definite and certain. It will be obvious that if the symptoms depend upon congestion, relief of the hyperæmic vessels ought to cure; and so it will. Local depletion is here the remedy. The blood may be withdrawn either by leeches or by scarification, the former being the more effectual, although slightly the more troublesome. Beside local depletion, everything which tends to cause congestion of the portal system should be removed. Therefore moderate purgation is desirable, saline aperients being given the preference. I doubt the advisability of ordering complete rest; moderate exercise does not aggravate the local symptoms, and is good for the general health. It is only necessary to warn the patient against over-fatigue and prolonged standing. Alcoholic drinks and heavy meals should be forbidden. In the simple cases about which I have been speaking the symptoms are not very acute. Great local pain and tenderness, elevation of pulse and temperature, thirst, loss of appetite, &c., indicate more than simple congestion, and require somewhat different treatment, a description of which does not come within the scope of this paper. The result of proper treatment in these cases is prompt and unmistakable. The patient is relieved at once. If the case be recent and the symptoms slight, it may be that a few days' purgation and one sufficient local bloodletting will be enough to remove the patient's symptoms, and that she will then go on menstruating, both as to quantity and pain, in the manner which is for her normal. In slight cases I believe that if the patient observe the ordinary laws of health, and is not exposed to any fresh cause of disturbance, recovery will often take place spontaneously. In slight cases, therefore, we may do enough if we simply try to amend anything that may be unhealthy in the patient's habits of life or surroundings, and give medicine to gently act on the bowels. Local depletion is not essential in every case, although it is the most effectual, speedy, and certain remedy. On the other hand, if we are not consulted until the patient has suffered for many months or years, lengthened treatment and repeated local bloodletting may be needed before menstruation becomes natural. The longer the case has lasted, the more the condition approaches that which we are accustomed to call chronic metritis, and the longer will treatment be required before recovery takes place. Even in the most chronic cases we can almost invariably relieve for the time by taking blood from the uterus, even though the benefit be not persistent. This form of congestive dysmenorrhœa is not only met with alone, but it often coexists with other morbid conditions. Therefore I would add, as a kind of corollary, that, as a general rule, the cases of uterine disease in which local depletion does good are those which are associated with this kind of congestive pain, in which we have the combination of scanty menstruation with pain in a florid, healthy-looking woman.

I will conclude by recapitulating the points to which I ask attention in this communication.

1st. The term *congestive dysmenorrhœa* is one which has no definite and generally accepted meaning, but is applied by different authors to different conditions.

2nd. That there is a form of dysmenorrhœa characterised by deficiency in the quantity of the flow, with increase in the pain, these changes occurring in a patient whose general condition is not such as would cause menstruation to become scanty, and who is otherwise in good health.

3rd. In such cases local depletion always relieves, and if the changes be recent, cures the patient.

4th. That in these cases the absence of appreciable morbid conditions other than congestion, and the prompt relief by local depletion, give good reason for thinking that the pain is due to congestion.

5th. That it would be well either to restrict the term "congestive dysmenorrhœa" to these cases alone, or at least to separate such cases from all the other forms of disease to which the term congestive dysmenorrhœa has been applied, the adjective *primary* being suggested as the best distinguishing prefix.

ERRATA.—In the first part of this paper, published in the number for Feb. 26th, "Monat" should have been *Nonat*, and "Courtz" should have been *Courty*.

West-street, Finsbury-square, E.C.

CASE OF ANÆSTHETIC LEPROSY TREATED BY STRETCHING OF BOTH ULNAR AND BOTH SCIATIC NERVES.

BY E. LAWRIE, M.B.,

PROFESSOR OF SURGERY, LAHORE.

KOUDA, Hindoo cooly from Gujerat, aged thirty, was admitted into the Mayo Hospital, Lahore, on Nov. 30th, 1880, suffering from anæsthetic leprosy. There were anæsthetic patches on the trunk and limbs, especially well marked in the ulnar areas of the hands and on the legs and dorsal surfaces of the feet. The hands were wasted, and he had lost the power of grasping to such an extent that he had been unable to follow his occupation for six months. Under chloroform both ulnar and both sciatic nerves were stretched. They were all thickened; the right ulnar was partially softened, and the left sciatic adherent to the fascia of the biceps. Listerism was employed in the treatment of the wound, which healed by the first intention.

After the operation the patient improved rapidly. The first sign of improvement noticed by himself was the return of power in the hands, and this was so decided that in a few days he felt able to work, and insisted on leaving the hospital. The result noted when he was discharged on Dec. 13th, 1880, was that he had regained power in the hands, and that sensibility was restored, though not fully, in all the patches on the hands, legs, and feet which had previously been anæsthetic.

Lahore.

LAST week a banquet was given by many of the leading citizens of Bristol to the Hon. Theodore Canisius, M.D., who, after six years' residence there as United States Consul, was about to leave the city. At the conclusion of the banquet an address was presented to Dr. Canisius, signed by the Mayor of Bristol and several of its more influential inhabitants.

WESTMINSTER HOSPITAL.

ATONY OF THE BLADDER; RECOVERY.

(Under the care of Mr. PEARCE GOULD.)

FOR the following notes we are indebted to Mr. Charles Rooke, dresser.

J. L——, aged fifty-seven, was admitted into Luke ward on Aug. 10th, 1880, suffering from retention of urine. He was a labourer with small but very firm muscles, no subcutaneous fat, bald and grey, and looked more than his age, and had marked arcus senilis. He had always enjoyed good health until twelve months before, when he found difficulty in passing his urine. This gradually increased until the night before admission, when after a hard day's work he was unable to pass a drop. He went to a medical man, who gave him some medicine and sent him to the hospital. The "difficulty" he noticed was a slow, feeble stream, and inability to empty his bladder, with frequency of call to micturate.

On admission the distended bladder formed a prominent tumour in the hypogastrium, reaching almost up to the umbilicus. The prostate felt from the rectum was hard and moderately enlarged. Mr. Gould passed without any difficulty an olive-headed catheter, No. 10 English scale, and drew off rather more than four pints of clear, acid, healthy-looking urine. The urine flowed slowly, falling vertically from the end of the catheter. The influence of respiration on the stream was evident. After the escape of about a pint the flow ceased, and the rest was forced out by the hand above the pubes, and when the pressure was relaxed air was heard to be sucked in through the catheter. The man was kept in bed on full diet, and his bladder was emptied by catheter night and morning. On Aug. 15th a mixture containing five minims of tincture of nux vomica was ordered to be given three times a day. The catheter used was always carefully washed in carbolic lotion—5 per cent.—before being used, and lubricated with carbolic oil—10 per cent. This appeared to cause some irritation of the meatus, and vaseline was substituted for the oil, and the irritation quickly passed away. There was no sign of any vesical irritation; the urine remained clear, acid, free from mucus and albumen, and the bladder gradually regained its expulsive power. Thus on Aug. 15th the patient could pass 4 oz. of urine by his own efforts, and on Aug. 17th this had increased to 10 oz., and thus he improved until on his discharge from the hospital on Sept. 15th there was only half an ounce of "residual urine" to be drawn off.

Remarks.—This case is an example of the extreme degree of atony of the bladder with complete retention of the urine, not unfrequently met with in connexion with chronic prostatic enlargement. The daily use of the catheter has long been recognised as the proper mode of treatment for such a condition, but the occurrence of decomposition of the urine with subsequent chronic cystitis have too often prevented the attainment of a perfect result. The case illustrates one application of antiseptic surgery to urinary surgery, and its value in preventing the decomposition of the urine can hardly be overrated. The result of the daily emptying of the bladder in leading to a gradual and almost perfect recovery of the bladder's power throws considerable light on the way in which this atony of the bladder is originally produced. For it is clear that it is not by obstruction to the outflow of urine with retention and stretching of the muscular coat of the bladder, nor is it from any local action of decomposed urine; but rather, it seems, from a small primary "residue" of urine. A few drachms which the bladder cannot evacuate have a paralysing influence upon the bladder muscle, which leads to the retention of a greater amount of urine; this, again, to further diminution of expulsive power, and so on until the stage of complete retention and atony is reached. The history of such cases before they come under treatment, as well as the results of catheterism, bear out this view. The symptoms often arising from a very small quantity of "residual urine" and the importance of its relief have been laid stress upon by Sir H. Thompson. The patient attends the hospital as an out-patient every month, and up to the present time (March 2nd) his condition remains as on the date of his discharge; he continues to draw off the few drachms of "residual urine" every night. The quantity has not increased since he left the hospital.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

EXOSTOSIS OF THE ANTRUM; REMOVAL OF SUPERIOR MAXILLA; DEATH.

(Under the care of Mr. RANSFORD.)

R. P——, admitted December 24th, 1879, a coloured seaman, aged forty-three, married, born in Liverpool; never had syphilis or other venereal disease; no disease in his family; brothers and sisters alive and healthy; father and mother died when he was young. He was much troubled with toothache and gumboils until about fourteen years ago, when they ceased. About this time he received a blow on the mouth, and a lump appeared on the left side of his face, which very slowly increased in size till it became as large as a pigeon's egg; a swelling began to appear on the left side of the roof of the mouth about the same time. These swellings were quite painless, and did not discharge. About six weeks ago the patient began to have little boils all round the external swelling, and the whole tumour began to increase rapidly, and his lower jaw began to get immovable. About three weeks before admission the swelling burst, with much relief, in two places on the left cheek. He had not been able to take solid food for some time.

On admission he was a feeble, thin-looking man, with feeble pulse, and the left side of his face bulging very much. His nose was pushed over to the right, his left eye pushed up, and two sinuses were discharging on the left cheek, one just over the malar bone, and one over the lower jaw, both leading to the necrosed malar bone. His lower jaw was rather fixed, and he was not able to open his mouth more than half or three-quarters of an inch; but on looking into the hard palate on the left side it was seen to be pushed down to the level of the crowns of the teeth. On introducing the finger the antrum was felt to be bulged outwards and downwards by a hard tumour. There was a most offensive smell from the mouth, and from the sinuses on the cheek. Taking into consideration its long history, with its recent rapid increase, and from its very offensive odour, it was believed to be an innocent tumour, probably fibrous, taking on a malignant nature. The odour was thought to be due to suppuration within the antrum, and with a view to explore it the left canine tooth was extracted, and a probe was introduced into its cavity; this came into contact with something rather hard, but no pus was seen. The patient was recommended to have the superior maxilla removed, which was done.

On Dec. 31st the operation was performed with the usual Fergusson incision, the orbital plate and the malar bone being removed. On lifting out the superior maxilla with the tumour, a large sloughing cavity was seen, from which there arose an offensive smell. This at first seemed to confirm the diagnosis as to the malignant nature of the growth. The bleeding, which was slight, was stopped; the surface was washed with a solution of chloride of zinc (40 grains to the ounce). All suspicious points were touched with the thermo-cautery. A sponge, wrung out with carbolic acid (1 in 20), was placed in the hollow, and the flaps were adjusted. After the operation the patient seemed very faint, and the pulse was very weak, so he was ordered two teaspoonfuls of brandy every second hour.

On Jan. 1st he took, during the night, a pint of beef-tea and nearly two pints of milk. Next morning pulse good—112; temperature 101°. The sponge was removed from the cavity, and he was ordered chlorate of potash as a wash for the mouth, also Condy's fluid. On the 2nd the wound was looking well; no tension; most of it had healed up by first intention; breath not very offensive; cavity syringed with

Condy's fluid. Food taken well. Temperature 102·6°; pulse 102; evening temperature 102·8°; pulse 104; respiration 20. On the 3rd he seemed a little weaker. Ordered half an ounce of brandy. Slept well during the night; no pain; cicatrix of wound looking well; sutures removed. Bowels open; no rigors; temperature 102°; pulse 100; respiration 24; morning and evening temperatures alike. Lint, saturated with boracic acid, introduced into the hollow caused by the removal of the growth. On the 4th, morning temperature normal; evening 100·8°. On the 5th, temperature morning and evening 99°; pulse 100; respiration 24. On the 6th, morning temperature 98°; pulse 88; respiration 16; evening temperature 102·8°; pulse 104; respiration 18. Great rise of temperature in the evening. No rigor. On the 7th the upper lip and left cheek swollen; much œdema of left eyelids. Morning temperature 101·2°; pulse 80; respiration 16; evening temperature 103°; pulse 100; respiration 20. On the 8th great fall in temperature; morning 101·6°; evening 101·2°. Notwithstanding the high temperature, the man had taken his food well—namely, four pints of milk, digested with pancreatised glycerine, as suggested by Dr. W. Roberts of Manchester, two eggs, bread-and-butter, sago, &c. On the 9th cicatrix at the situation of the old sinus over the malar bone had given way; an opening the size of a pea inside of wound seemed to be covered with crusts of dry pus. No active granulation seemed to be going on. Cheeks not so swollen. Bowels regular. Further fall in his temperature, morning 98·8°; evening 99·2°; pulse 90, compressible; respiration 20–26. In the evening a blush extending over the forehead was noticed. On the 10th the temperature was rising: morning 100·2°; evening 101·6°. The blush had not extended, but was rather less. Discharge from mouth not so free, nor so offensive; felt chilly in the morning. On the 11th redness had disappeared; discharge was free from the mouth; patient complained of soreness in the mouth. The temperature had fallen to 97° in the morning; evening temperature 99°; and so he went on, his temperature rising and falling, but all the time eating and sleeping well, yet without gaining strength. On the 25th he complained of great pain along the left sciatic nerve; ordered a blister, and the surface to be dusted with powdered morphia. Temperature 99°; pulse 70. Next day he did not complain of any pain; temperature normal; appetite good; no action about the site of the old sinus over the malar bone; no granulations; no pus. On the 28th, morning temperature 99°; pulse 100; respiration 16. At about one o'clock he had a rigor; at 1.30 P.M. his temperature had risen to 103·8°; his pulse to 144. Ordered five grains of quinine, every four hours. At 2.30 his temperature was 105°; pulse 160. At 3.30 it had fallen to 104·2°; his pulse to 138. No pneumonic signs; no pains in any part of the body. 8.30, temperature 105°; pulse 104. On the 29th, pulse 126; temperature 103°; skin hot and dry; some cough; no sputa; tongue dry and brown; bowels open. On the 30th, seemed better and stronger in the morning, and took some food, but soon after the house-surgeon left him he suddenly collapsed, became unconscious, and died.

Necropsy, twenty-four hours after death.—The whole of the seat of operation had healed up both inside and outside, with the exception of a small portion of the skin wound over the malar bone at the situation of the old sinus, where an oblong opening about half an inch long existed. Some of the veins in the neighbourhood contained pus. No secondary deposits anywhere. The heart was flabby, no fatty degeneration. "The tumour" (Report by Mr. F. T. Paul, now in the Museum of the Liverpool School of Medicine) "weighed four ounces, size two and a half inches by two and a quarter inches. The growth consists of dense osseous tissue, and has generally a rounded form. It is discoloured and fetid, and has no connexion with any other bone, nor are the soft tissues genuinely adherent to it. All the upper part is quite bare. The front and under surface are loosely covered with facial tissues and mucous membrane. A molar tooth is firmly rooted in the mass, and is not carious, though probably dead. The osseous tissue is very hard but brittle, and is as discoloured in the centre as outside. The texture is somewhat more open in the middle. The nature of the tumour seems to be that of an exostosis or osseous hypertrophy of some part of the superior maxilla, certainly involving the alveolar process. During its growth it probably caused the absorption of most of the bone by pressure, and ultimately necrosed through lack of nourishment."

Remarks.—This tumour somewhat resembles Mr. Hilton's case, reported in the Guy's Hospital Reports, vol. i. p. 493, in the fact that the tumour had necrosed spontaneously, but it differed from it in structure, as it was not hard and polished like ivory. If it absorbed the palate process, the orbital, the zygomatic, and the internal and external walls of the antrum, in front it had the thin anterior wall of the antrum covering it. The alveolar process also existed.

YORK COUNTY HOSPITAL.

NEEDLE IN KNEE; AMPUTATION; RECOVERY.

(Under the care of Mr. JALLAND.)

FOR the notes of this case we are indebted to Mr. F. H. Weekes, house-surgeon.

S. B——, a dressmaker, aged twenty-five, was admitted on May 17th, 1880, suffering from acute synovitis of her right knee. Close to the outer margin of the patella a minute puncture could be seen, and this the patient stated had been caused in the following manner:—Six days prior to admission the patient ran a needle with considerable violence into the knee, but this she pulled out immediately. The puncture indicated the point of entrance. On the day following the accident the knee became hot, swollen, and painful, so that the patient was compelled to remain in bed until her admission into the hospital. As far as could be ascertained, no rigors had occurred.

On admission, a back-splint and ice-bags were applied to the knee. During the same afternoon a slight rigor took place, and the evening temperature was 103°. The knee continued to increase in size, and the pain in it became so severe as to greatly interfere with sleep at night. The appetite also became very bad. On May 20th, after the occurrence of a rigor, an incision was made over a prominent part of the joint, with the aid of anæsthetics and antiseptics, and about an ounce of exceedingly fetid pus evacuated. This cavity, which probably communicated with the joint, although this fact was not certain, was washed out with antiseptics, had a drainage-tube inserted, and gauze applied as a dressing. In the evening the temperature was 103°, the same as it had been on previous evenings. The patient had a good night's sleep, and the pain in the knee was much less next morning, when the temperature was 98·8°. Evening temperature 98·2°. On the 22nd the morning temperature was 98·8°. The wound was dressed. Free discharge of offensive pus. Evening temperature 103°, and the patient had a very restless night. The pain in the knee was very severe next morning. During the afternoon (23rd) the patient was seized with a rigor, in which the temperature rose to 106·4°. After this the wound was dressed, and a free incision made on each side of the patella into the joint cavity, with the effect of setting free several ounces of very offensive pus. The knee was again well cleansed with carbolic lotion, drainage-tubes were inserted, and the whole was dressed with gauze, everything being done, as on the former occasion, with antiseptic precautions. The wound was dressed daily on the Listerian plan, but it was never aseptic. The evening temperature averaged 103°. On the 28th pus was found to be running up the back of the thigh; for this an exit was made, and one hour afterwards the patient had a rigor, with a temperature of 105°. The soft palate ulcerated, interfering a good deal with deglutition, but under the local use of perchloride of iron the ulcers soon began to heal. A careful examination of the patient showed that the lungs, liver, kidneys, and the joints, excepting the knee, were healthy. The evening temperature continued to average 103°. The appetite is improved; and with the aid of chloral a fair amount of sleep at night is procured.

On June 5th the gauze dressings were discontinued, and charcoal poultices were substituted. An accumulation of pus in the popliteal space was evacuated by a counter-opening, all the other wounds discharging freely a fetid pus. On the 7th a large abscess was opened on inner side of thigh, a short time after which a rigor took place with a temperature of 104·5°. On the 12th the patient was very pale, extremely thin, taking but little food, subject to profuse perspirations and rapid variations in temperature. Nearly every day a fresh accumulation of pus was found, requiring to be opened. None of the wounds healed, and all discharged a profuse, fetid, purulent fluid. On moving the knee distinct grating can be felt. Under these circumstances, amputation at the lower third of thigh was performed by Mr. Jalland with antiseptic precautions. The patient had a good night's sleep, and there had been neither vomiting nor hæmorrhage. As there was much discharge the wound was dressed next day; all looking well. On the 15th the wound was again dressed, and most of the sutures were removed. On the 18th there was slight discharge; the wound was dressed. On the 20th the wound was dressed again; all sutures and drainage-tubing were removed; the flaps were almost entirely healed.

On July 5th the stump was examined, and found to be quite well and free from pain; the dressings were discontinued. The general health was much improved, the patient taking her food well, and sleeping through the whole night; allowed to get up. Temperature has been normal since amputation. On the 17th discharged well.

Remarks.—We are frequently in the habit of pushing the needle of the hypodermic syringe into various parts of the body without producing any serious effects, that one is astonished to find what severe mischief may be set up by a simple needle puncture. In this case the girl said positively that the whole of the needle came out, so that the damage to the knee-joint must have been set up by the septic matter conveyed on the needle.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

A Probable Cause of Lead Colic.—The Ox Aorta Ligature and the Variability of Catgut.

THE ordinary meeting of this Society was held on the 8th inst., the newly elected President, Dr. A. W. Barclay, taking the chair for the first time.

A paper was read "On a Probable Cause of Lead-colic," by Dr. C. HILTON FAGGE. After referring to the fact that in certain observations on the nature of the lead line in the gums, published in the fifty-ninth volume of the Transactions, he had been anticipated by a French physician, M. Cras; the author remarked that both he and M. Cras had on theoretical grounds suggested that it was almost certain that sulphide of lead must be formed in the intestinal mucous membrane of persons exposed to the action of the metal, by the reaction of the sulphuretted hydrogen of the intestinal gases upon a soluble combination of lead circulating in the capillaries. The author had since had few opportunities of examining the bowel in patients who had had symptoms of lead-poisoning. In two instances the results were negative. In the other two instances a marked and extensive blackening of the interior of the bowel was observed. Dr. Stevenson was kind enough to make analysis of the discoloured contents of intestine, and to compare them with analysis of healthy pieces of intestine from the same patients, and he proved that there was an excess of lead in the blackened part, amounting in one case to as much as 320 times the quantity present in the non-coloured part.—Dr. DOUGLAS POWELL asked whether any microscopical examination of the intestine was made, as the precise seat of the deposition of lead might explain whether it occurred by direct action of the sulphuretted hydrogen on the lead in the bowels, or on the lead on the way to being eliminated by the large intestine after its absorption higher up. The treatment of lead colic by iodide of potassium was generally followed up by purgatives, in the view that the lead is so eliminated.—Dr. R. THOMPSON said it was important to remember there were two ways in which the intestine might be blackened by lead. It may be that the metal is deposited in the mucous membrane from the blood, and converted into the sulphide by the intestinal gases, or that, like bismuth, it is acted upon by these gases before absorption. He had found in those who took bismuth that the mucous membrane of the large intestine was blackened by the sulphide of bismuth, which by means of chromic acid could be converted into the yellow chromate. He referred to Dr. de Mussy's observations on the Claremont cases treated by alkaline sulphide baths. The skin was blackened—a condition which Dr. Thompson had found in another case similarly treated to be due to the deposit of sulphide of copper, from the action of the solution in the metal of the bath.—Dr. POWELL added that Dr. Fagge's views as to the cause of the blue line on the gums were confirmed in a very marked case of lead paralysis without any such blue line being present. This absence of the blue line was associated in the case with a complete freedom from tartar on the teeth. It was well known also that no blue line appears on edentulous gums.—Dr. CAVAFY asked Dr. Fagge whether he regarded the deposition of the sulphide of lead in the intestine as the cause of lead colic, and, if so, did he think it acted on the nerves of the intestines. *Primâ facie* there was no reason, if this were the case, why the deposition of the salt on the gum should not give rise to toothache.—The PRESIDENT pointed out that lead was undoubtedly absorbed into the blood, and its action was not merely local like that of bismuth. Was the lead only partially absorbed, or was it eliminated again into the alimentary canal, as Dr Powell stated. The presence of the discolouration in the large intestine was due to the larger amount of sulphuretted hydrogen in that portion of the bowel. He presumed that lead colic had its seat in the small intestine, so that it could not be attributed to the existence of the deposit.—Dr. FAGGE, in reply, said that a microscopical examination was made in the first case, and showed the black granules to be deposited around the capillaries of the villi, just as on the gums. Dr. Thompson's remarks as to the discolouration of the intestine from bismuth were suggestive. Bismuth blackened the tongue, and Brinton suggested that it also produced a blue line on the gums, but this Dr. Fagge had not been able to confirm. The lead line was due to the deposition of the metal in the tissue of the gums, and its conversion into sulphide by the tartar. It was by following out the line of inquiry thus suggested that he had sought for discolouration of the intestinal mucous membrane, where a much greater amount of sulphuretted hydrogen would be in operation than in the gums. There was no reason to suppose that any large quantity of lead would escape absorption. He did not adduce the fact of deposition as explanatory of lead colic, which, however, had, he thought, its seat in the large intestine.

The following is an abstract of a paper "On Experience and Specimens of the Ox Aorta Ligature, and some Remarks on the Variability of Catgut," by Mr. RICHARD BARWELL, F.R.C.S. The object of a paper read before this Society two years ago was, firstly, to point out the cases of aortic aneurism which might be benefited by deligation of the right carotid and subclavian; secondly, to show the advisability of leaving all the coats of arteries tied in continuity intact; thirdly, to introduce a flat ligature to carry out this object. The experience, necessarily small, which I could then adduce may now be supplemented by two additional cases of aortic aneurism treated by tying the above-named vessels with the ox aorta ligature; thus there are three in all. 1. My own case; lived sixteen months in fair health and comfort. 2. A case of Dr. Lediard (now of Carlisle); lived ten months. 3. A case by Dr. Wyeth of New York; is now alive and in good health. Besides these I have to report a case in which I tied for aortic aneurism the vessels on the left side of the neck. The operation failed to prolong, but I do not know that it shortened, life. The patient survived thirty hours. The parts of my first case, and of Dr. Lediard's case (by the kind permission of Dr. Hopkins), are on the table, as are also certain specimens removed from the last case. The arteries of the first have been injected; the carotid ligature was *ab origine* tied too loose. It was the first artery I had tied with the ox aorta, and I attributed the almost immediate return of temporal pulse wrongly to free collateral circulation. The loop of ligature probably remains on the vessel. The subclavian is quite closed, and, being slit lengthwise, shows the tunics entire. Collateral circulation is well established. Of the second case Dr. Lediard writes: The aneurism is filled with very firm clot. Nothing could have been more satisfactory than the action of your ligature in this case. The vessels were entirely occluded, there being no trace of the bands seen, but a firm clot above and below the seat of constriction, such as is usual in vessels tied in continuity. The parts from the last case are the subclavian, showing where tied no injury to any of the coats—the severed ligature from that artery. The other ligature with the knot entire, and showing no tendency to loosen. Four other vessels have been tied with this ligature—two iliacs (Mr. Holmes and Mr. Johnson Smith), two femorals (Mr. Bellamy and Mr. Barwell); in these four cases the aneurisms did perfectly well, the wounds healed at once, and nothing more was seen of the ligature. The twelve deligations are more than sufficient to show that the ox aorta ligature becomes absorbed with sufficient slowness to be perfectly reliable in tying vessels in continuity. They show this with the more force because this material is not prepared, the ligatures are cut from the fresh aorta and dried, hence they are uniform. What has happened with those that have been employed will happen with all. This power of becoming gradually absorbed is common to all the soft connective tissues, provided they are perfectly fresh—i.e., not decomposed. The submucous tissue of sheep's intestine, of which catgut is made, would, if it were dried while fresh, act like other soft connective tissues, with no need whatever for after preparation. But in the manufacture of catgut this structure is separated from the rest by processes of scraping, a procedure which would be impossible unless the intestine were to some extent decomposed. The various modes of preparing catgut into ligatures are devices for getting rid of the results of this decomposition. Catgut sutures, more easily watched than ligatures, dissolve in very various periods, though prepared in identically the same way. One of the chromic acid processes gives cords, dissolving some in nine, some in nineteen days. The usual (old) method has supplied me with sutures, some of which have dissolved in forty-eight hours, some remained persistent, and had to be cut away on the fourteenth day. This results from the various degrees of decomposition in the catgut itself; it cannot happen with tissues that are fresh and require no after-elaboration. When a piece of catgut is buried deep round a large vessel, we cannot be more sure of its behaviour than we can predict the duration of the sutures; nor can we deduce from the good behaviour of certain such ligatures that the particular piece supplied us will act properly. For tying large vessels near the heart, or lying deep, a material whose action is more uniform, which is therefore more reliable, is essential. —Mr. LISTER said it was interesting to learn that the tissue of the aorta resisted absorption for so long a time. He disputed the statement that the preparation of catgut by scraping was due to putrefaction. On the contrary, the fresher the intestine the better the quality of catgut. The rapidity of absorption of improperly prepared catgut was not due to the state of putrefaction, but to the difference between cellular tissue and aortic tissue. Unlike Mr. Barwell, he had found old catgut less readily absorbed than new catgut; but by the new mode of preparation he had described both kinds were brought to the same level in this respect. Speaking of the desirability of dividing the inner and middle coats of an artery tied in continuity, he said that in one of his early experiments (using a ligature of a strip of ox's peritoneum) he had tied the carotid of a calf without dividing the middle coat; but this did not prove that the division of the inner and middle coats was not essential. Indeed, general experience went to show the desirability of such division—incomplete ligature or insufficient injury to the coats being followed by a tendency to the opening up of the vessels. He always applied the catgut ligature so as to divide the inner and middle coats; although whether this was absolutely necessary when the catgut was of the best form—(i.e., not too readily absorbed), he was not prepared to say. Referring to the case recently related by Mr. Treves, where the opening up of the carotid artery after antiseptic ligature was ascribed to the rapid healing of the wound, the subclavian in the same case being perfectly occluded, and the wound not antiseptic, Mr. Lister showed a specimen where the external iliac had been tied for femoral aneurism. An antiseptic silk ligature was used, and the wound followed an antiseptic course. The external iliac artery was wholly occluded. A small knot of silk remained, and a minute abscess occurred at the seat of ligature. Death took place one year after ligature. Here was evidence of extensive obliteration following the application of an antiseptic ligature. On the other hand, secondary hæmorrhage from the distal side followed sometimes on the use of ordinary ligatures, from absence of coagulation; and such cases proved that suppuration around the vessel did not invariably lead to obstruction. That failures in occlusion might follow the use of catgut, when not of proper quality, he was fully aware. Such failures were recorded, but the multitude of successful cases were not. He felt sure that if all the cases were reckoned in which the catgut ligature was applied to arteries in their continuity with strict antiseptic treatment, the results would compare very favourably with other methods of ligature. But if surgeons use the catgut ligature and allow the wounds to putrefy, good results could hardly be hoped for. Such cases as those recorded by Mr. Bryant were due to the lucky chance that union by first intention took place in the deep parts of the wound, thus preventing putrefaction around the ligature. He ventured to think that surgeons who undertake such operations are bound to take measures to avoid putrefaction. At the Cambridge meeting of the British Medical Association he adduced a long series of cases in which no putrefaction occurred, and since then he had had many more cases without putrefaction in a single instance. He did not state this in a spirit of boasting, but simply as a matter of duty. His cases at King's College Hospital were not dressed by himself, but by the house-surgeon and dresser, to whom the praise was due. Surely if such results can be obtained it was worth while to master the simple measures of preventing putrefaction. By the use of such measures the two great dangers to ligature of arteries in their continuity—viz., secondary hæmorrhage and diffuse suppuration —may be avoided, and these were objects deserving the best attention.—Mr. TREVES said that in the case he had reported where the carotid after antiseptic ligature became partially reopened, the catgut was of good quality and the coats divided. The small abscess at the seat of ligature in Mr. Lister's case of iliac ligature was hardly consistent with an absence of inflammatory reaction. With regard to the mode of tying arteries alluded to by Mr. Barwell, he had found by experiment that it was almost impossible to divide the inner and middle coats when a double hitch was made in the ligature before tightening it.—Mr. LISTER pointed out that the abscess referred to was of very minute size, and could not have produced any inflammatory change around the vessel.—Mr. HEATH remarked that in one of Mr. Barwell's specimens the carotid artery which had been ligatured was quite pervious, and showed no trace at all of any ligature. The subclavian in the same specimen was completely obliterated. Was there division of its internal and middle coats? He doubted if the surgeon could so graduate the force he applied as not to cut through the inner and middle coats.—Mr. BARWELL, in reply, said that much depended on the mode in which the ligature was tied. He had found that, owing to the roughness of catgut, it was difficult to tell from the sense of resistance whether the artery was being sufficiently pressed on or not. The carotid artery in the specimen alluded to by Mr. Heath had been incompletely tied. The condition of the coats of the subclavian was not ascertained in that specimen; but in another the internal and middle coats were not divided. By means of flat ligatures it was hardly possible to tie the vessel so tightly as to divide the inner and middle coats. He had been struck with the fact that the recorded cases of ligature of the largest vessels were fatal from secondary hæmorrhage, and it struck him that this would be obviated by keeping the artery entire. He did not at all suppose that this could only be done by means of the ox aorta ligatures. Mr. Pollock last year tied the subclavian and carotid successfully, using ligatures of kangaroo tendon. Professor Wyeth had used ligatures of the whole thickness of the aorta. Why should not catgut act in the same way? He certainly thought the preparation of catgut was attended by putrefaction, and had attributed its unreliability largely to this. One surgeon used chromic acid many times the strength of that used by Mr. Lister to make the catgut reliable. In the old methods of preparation Mr. Lister had got perfectly reliable ligatures; but in one case where he had supplied Mr. Pemberton with such a ligature a large abscess formed, and the ligature came away. In a case of double popliteal aneurism Mr. Bellamy tied one femoral with the aortic ligature, and with good result. The same operation performed on the opposite leg with the chromic catgut ligature supplied by Mr. Lister was followed by the formation of a sinus leading down to the ligature, the rest of the wound healing by first intention. These different modes of preparing catgut ligatures may suit one or other form of catgut, but not all, and therefore he said the catgut ligature was not a reliable one. Nor did experiments in blood serum touch the point, for the experiments should be made in the living body in the midst of the tissues.

PATHOLOGICAL SOCIETY OF LONDON.

Unilateral Hypertrophy of Head and Face.—Glioma of Cord, with Dilatation of Central Canal.—Fœtal Tumour.—Vesical Calculus in Dog.—Syphilitic Disease of Skull.—Malformation of Heart.—Cancer of Bladder.—Leucoderma.—Zeroderma.

The ordinary meeting of the Pathological Society was held on Thursday, March 3rd, the President, Samuel Wilks, M.D., F.R.S., in the chair. There was but a small attendance, probably owing to the meeting not being held on the usual evening.

Mr. Barwell showed the head and also a model of a case of Unilateral Hypertrophy of Head and Face. He met the boy, the subject of this deformity, accidentally six years ago. He was then about seven years of age. Last year he tied the right carotid artery just above the clavicle, more as a preliminary treatment than in the hope of bringing about a permanent cure. On the sixth day the boy died from secondary hæmorrhage. The condition was congenital, and the disproportion between the two sides was steadily increasing. The enormous development of the right side of face with the infantile character of left was the great characteristic, giving a very grotesque appearance. The tissue was soft, with a patch of ichthyosis of recent formation, and rapidly growing near the ear. The bones were also involved, as shown by casts of the upper and lower jaws. The cranial sutures and raphé of the tongue were pushed quite over to the left of the middle line. Was the cause some affection of trophic nerves, or of the middle coat of the arteries, which may have also led to the fatal hæmorrhage? Unilateral overgrowth of the head and face is not very uncommon; he had often seen it. Also overgrowth of right side of trunk, which is one of the causes of lateral curvature of the spine; it is very occasionally seen on the left side—not more than one in fifteen of the opposite condition.—Dr. N. Moore asked Mr. Barwell whether there was any new growth in the large mass. The appearance was not like a new growth; but such might be its cause if the tumour arose very deep. He once saw a young woman with a very large right hand, the left being small, of natural size; her skull and the rest of her body were quite symmetrical.—Dr. Wilks asked if these cases were to be associated with cases of atrophy on one side, as in wryneck, and whether the pathology was the same in the two sets of cases.—Dr. Goodhart asked whether the boy was mentally sound.—Mr. Barwell replied that he was sound, but ignorant. The nerve condition at the bottom of this case is not the same as in wryneck. The nervous condition in wryneck he thought to be more connected with the spinal nerves than with the sympathetic, and the appearance of the two is different—one is dwindled, the other gigantic. In cases of difference in length of limbs merely, the change may be explained by injury to the epiphyses. There was no tumour or new growth; the bones were all affected, and the ichthyosis and size of tongue showed that it was hypertrophy and not new growth. Some years ago he showed to the Society a case of overgrowth of the parts of the face supplied by the facial arteries. Ligature of these arteries did no good.

Dr. Whipham showed a specimen of Tumour of Spinal Cord with Dilatation of Central Canal. The patient was a bricklayer, aged thirty-three, in St. George's Hospital, under Dr. Barclay. He suffered from numbness in both hands, with weakened grasp, especially on right side. He had worked in white lead. He improved under galvanism. Later on he had paralysis of arms, legs, and intercostal muscles; there was wasting on the right side, dropping of the hand; and the forearm was held up by the left hand. A large bedsore developed; later on he died of exhaustion. The post-mortem examination showed red hepatisation of left lung, congestion of right; upper end of cord much enlarged and fluctuant. This was found to be due partly to an infiltrating new growth, and partly to cavities in the position of central canal, lined by a shining membrane containing a soft gelatinous mass in minute structure resembling glioma. The central canal of the cord below the swelling was enlarged. The tumour in the upper part was glioma, there the lymphatics were dilated and filled with lymph, the normal nervous tissue being nearly entirely destroyed. No traces of the epithelium of the central canal could be found. In the dorsal region the anterior horns of grey matter were widely separated by nerve tissue, and the distended canal flattened; ganglion cells compressed. In part, however, the white nerve tissue was also evidently compressed, and homogeneous masses of serum were found. This case appeared to furnish one explanation of cases of cavities in the cord. Dr. F. Taylor has recorded a case without any new growth, but in this case the cavity was probably formed by the new growth spreading into and dilating the central canal.—Dr. Horrocks asked if the superficial and tendon reflexes were tested in this case.—Dr. Whipham replied that the case was under observation many years ago, before the days of these reflexes.

Mr. Pearce Gould read for Mr. C. Macnamara the description of a Tumour removed from a female child under his care at the Westminster Hospital, a photograph of the child and the tumour were shown. The child, two months old, had the tumour springing from the back of the sacrum and buttock; it had considerably increased since birth. Mr. Macnamara removed it by the chain écraseur after having expressed the blood from it by Esmarch's bandage, and reflected up two flaps of skin from the pedicle. The tumour was examined by Mr. Pearce Gould. The tumour, ovoid in shape, with an even surface, was covered with skin, which was raised in a thin, narrow, fringe-like band half round its base. Projecting from the left side was a curved finger-like process. On section one large cyst and several smaller ones were found, lined by a thin smooth membrane, and containing serous fluid. The greater bulk of the tumour was solid, and consisted of fœtal fat, in which bands of fibrous and unstriped muscular tissue were seen, and an irregularly-shaped jointed piece of cartilage, partly ossified, was embedded; the cartilage extended into the finger-like process as a chain of small nodules firmly jointed together. Mr. Macnamara stated that these tumours were of interest to surgeons, because it was sometimes difficult to determine whether their removal would be attended with serious injury to important viscera, and to pathologists because they formed a link of connexion between united twins and dermoid cysts. This tumour was evidently an impregnated ovum, which had not arrived at maturity, and had early become attached to the fœtus, of which it subsequently formed a part, and grew with its growth.—Dr. Wilks said that this case was no doubt the remains of another ovum; in many cases it was not at all clear what the origin of the tumour was.

Mr. Treves showed a Vesical Calculus of a Dog which died of uræmia. It completely filled, and was adherent to, the bladder. The dog had convulsions and coma. There were frequent micturition, pain, passage of blood, and irritation at the end of the penis.—Dr. Wilks asked if the dog could jump. Sir A. Cooper used to make his patients jump off a chair, and if this produced pain it was held to be diagnostic of vesical calculus.

Dr. N. Moore showed a specimen of Syphilitic Disease of the Skull from a man, aged forty. The whole surface of the calvaria looked worm-eaten. When fresh the little pits were filled with yellowish-red soft material, in structure like a recent gumma; the brain was unaffected. There were scars of gummata in liver. A very distinct scar on the penis and many on the legs, and necrosis of left thyroid cartilage also bore evidence of the existence of syphilis. During life there was very little sign of the disease of the bone, only two small patches on the scalp, which might have been mistaken for eczema. The skull resembled those found in barrows which have been deformed by the roots of plants, but the patches on the interior are not found in the bones altered by rootlets.—Dr. Wilks remarked that any signs of repair would distinguish these cases from those referred to by Dr. Moore. Were there no symptoms during life?—Dr. Moore replied that there were none.—Dr. Wilks said that many cases of destruction of skull were considered to be due to mercury, but there was very little evidence—none, in fact, to prove this.—Dr. Moore said there was no evidence of this man having taken mercury continuously at any time.—Dr. Barlow remarked that the skull showed some changes quite unlike the action of rootlets; there was an eroded surface with slight thickening, and also a cicatrix in the bone. M. Parrot had not referred to this form of skull-syphilis as evidence of that disease in prehistoric times; but to a form with considerable hyperplasia of bone with little or no destruction of bone. M. Parrot's specimens show actual new osteophytic deposits, and this specimen did not throw a slur upon M. Parrot's demonstration. All bones exposed to water and buried show a granular and osseous surface.

Dr. Norman Moore exhibited also a very rare Malformation of the Heart, in which all four cavities communicated together. The patient was a girl, aged seventeen, who had enjoyed good health up to the age of seven, after which she had several attacks of rheumatic fever. She was admitted to hospital in a dying condition. There were found a systolic and a presystolic murmur at the apex, and a presystolic thrill. The impulse of the heart was heaving and irregular, and the chest wall was bulged over the heart. The septum ventriculorum was complete; foramen ovale closed; coronary sinus well developed. The musculi papillares of the mitral valve both arose from the outer wall, and were abnormally close together; the mitral cusps were fixed close to the aortic orifice, they were thickened, and had small growths upon them. The aortic and pulmonary valves were normal and competent; the aorta was healthy, and the pulmonary orifice was twice as wide as the aortic; coronary arteries normal; ductus arteriosus closed. On opening the pericardium the external peculiarities of the heart were enormous dilatation of both auricles, and of the right ventricle; moderate dilatation of the left ventricle. The bifid character of the apex, which was nearly as great as in Dugong's heart. The septum auriculorum did not meet the septum ventriculorum, and there was a large opening below it but above the flaps of the auriculo-ventricular valves, one part of each of which was attached to the septum ventriculorum just below that opening. Thus the auricles were in communication with one another, and each auricle with both ventricles. In a large number of cases of cardiac variety, as such cases may be called, there is some other departure from the normal, and in this case there was a large omphalo-mesenteric diverticulum of the ileum. In the post-natal attacks of acute rheumatism the very minute growths on the mitral and the slight thickening of the bone of the septum of the auricles probably occurred. The right side of the heart was free from any sign of endocarditis, which would also seem to justify the belief that the endocarditis of the left side took place after birth.

Mr. Davies-Colley showed a case of Epithelioma of the Bladder, with Calculus in Kidney and Bladder. A man, under Dr. Habershon's care in Guy's Hospital, died at the age of forty-seven. Twenty-one years ago he had a large stone removed from the bladder, and ever afterwards suffered from a pricking pain at the end of the penis. Five years before death he had passed blood, and Mr. Davies-Colley sounded him; no stone was found. These hæmorrhages were repeated many times. Last year his legs swelled, and he became very ill, and died in October with symptoms of gangrene of the lungs. Small patches of cancer were found in liver and lungs, and around one of the latter was a patch of pneumonia becoming gangrenous. The bladder was occupied by a shaggy mass, the size of the hand, which had spread into the lumbar glands, and had obliterated the vena cava. The left kidney was very dilated and occupied by a large branching calculus of triple phosphate. The point of interest was the occurrence of vesical cancer twenty-one years after the removal of a stone. This was hardly a coincidence. The pricking pain felt ever since the operation was probably due to a scar, which ultimately gave rise to cancer. The tumour was an epithelioma. The growths in the liver and lungs were not examined microscopically. Dr. Fagge had shown a case of cancer of the bladder due to frequent catheterism. He had under his care at the same time another patient with vesical hæmorrhages, who had had a stone removed from the bladder. — Dr. Wilks had seen a few cases of cancer of bladder with calculi, and several of cancer of gall bladder and ducts with biliary calculi; and Frerichs had told him that he had frequently noticed the latter association.—Mr. Morris asked how long the tumour in the bladder had lasted, and whether the stone twenty-one years before could be really the cause of a cancer so long after.—Mr. Davies-Colley could not say how long the cancer had lasted, but five years before death he had passed blood in his water, which, in his opinion, came from the bladder.

Mr. Startin showed two living specimens, one a case of Leucoderma, a man who had lived in Canada for three years. A year after coming home he noticed several symmetrical patches of skin and hair devoid of pigment. Sensation was perfect in these patches. The other was a case of Zeroderma in a child ten years old. Both palms and soles were affected with dense layers of hypertrophied skin; it began at the age of twelve months; there was no history of syphilis. The case was almost if not quite unique.—Dr. Payne asked if the general colour of the skin of the man with leucoderma was darker than usual. The two conditions of excess and absence of pigment were usually combined. The pigment in the darker part in one case examined was curiously near the surface, as if the pigment had been set loose from the Malpighian layer, and might be expelled at the surface and so cause the blanched patches of leucoderma.—Mr. Startin said there was no increased pigmentation.—Dr. Wilks asked if local treatment for the hand had been tried.—Mr. Startin was using liquor potassæ and spirit locally, and tonics and arsenic internally.

Dr. Abercrombie showed a card specimen of Sarcoma of the Testicle, removed the same day by Mr. Morgan from a child four years old.

Mr. Shattock showed a card specimen of a Congenital Sacral Tumour growing into the pelvis, sarcomatous in character.

Dr. Horrocks showed a Heart removed from a young woman recently under Dr. Fagge's care, aged twenty-three. She was in good health up to the age of ten; she then suffered from rheumatic fever, scarlet fever four years later, and a year after rheumatic fever again, when there was well-marked evidence of valvular disease of the heart, systolic and presystolic murmur at the apex, with thrill. The mitral and tricuspid valves were found to be "button-hole" and thickened, but there were no vegetations; both auricles were dilated. It was an illustration of the facts elucidated by Dr. Fenwick; for the patient was a young woman, and there was a history of rheumatic fever. The stenosis, although sought for during life, was not recognised; and this case shows that that condition may exist without any signs to declare it. There was no special appearance of youth in this patient, which has been noted in others and much commented on.—Dr. Wilks said Dr. Fenwick had mentioned one case of tricuspid stenosis in which a presystolic murmur to the right of the ensiform cartilage was heard. —Dr. Fenwick said that in both the cases he brought forward such a murmur was heard. In thirty-two out of forty-six cases the murmurs heard had been noted, and in nineteen or twenty those at the xiphoid cartilage were different from those at the apex, in thirteen presystolic, and in six or seven systolic. He asked if there was any increased cardiac dulness on the right side in Dr. Horrock's case. This was very often found on account of the enormous dilatation of the right auricle. In twelve out of thirteen cases collected by Dr. N. Moore the patients were females. Dr. Coupland had sent him notes of two females, and Dr. Peacock also two females. — Dr. Horrocks, in reply, could not say whether the cardiac dulness was increased to the right or left, but from post-mortem appearances he should be inclined to think the dulness greater to the left; the increased breadth of heart was mainly on the left side from the enormous left auricle; the heart, too, was pushed over to the left.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Renewal of Upper Part of Femur after Removal for Necrosis.—Ataxy with Knee-phenomenon.

At the meeting of this Society on February 28th, Mr. F. J. Gant, president, in the chair—

Mr. Thomas Bryant exhibited a female child, aged six, in whom the upper part of the femur, with its head, had been renewed after the removal of the orginal bone in November last. The case had been brought before the notice of the Society on the 26th of that month, and the preparation was shown, including the epiphysis of the right femur, neck, trochanter, and half of the shaft. The disease had been one of acute necrosis, and the femur with suppuration of the hip-joint, following an attack of acute periostitis. At the time of the operation in November the only evidence of periosteum was seen at the lower neck of the dead shaft, which was surrounded by an ensheathing casing of new bone; and as no attempt to form new bone at any other spot was possible, it was reasonable to conclude that there was no other periosteum present; for if there had been new bone would have been formed by it as certainly as it had been formed about the lower end. After the operation in November everything went on well; the wound was kept clean by means of a drainage-tube and the washing by iodine water, and was dressed with terebine and oil. The limb was kept quiet and in a state of slight extension by means of the double splint with its elastic pulley. No elevation of temperature followed the operation or attended the progress of repair, and in less than a month the wound through which the bone had been removed had quite healed; indeed, the progress of the case was so rapid and satisfactory that Mr. Bryant said, had he brought the case forward to illustrate a new form of dressing wounds he might with some show of reason have held it forth as a marked example of its value, and been weak enough to suggest that such a result could not have been obtained by any other method than the one he was advocating. But during this time other changes were taking place, and from the present condition of parts these changes were clearly the formation of new bone, with a new joint, for within three months of the operation the case was found to present the same features as it now exhibits—that is, the complete reformation of the bone that had been removed with a new joint. This was demonstrated by the smooth movement of the femur in the acetabulum, and the perfection of the movements of the limb—flexion, extension, adduction, and rotation of the limb existing at the present time almost as perfectly as they do in a sound joint. The new bone was, however, about one inch shorter than the opposite. How this new bone had been reformed was a somewhat difficult problem to solve, since it seems very clear that there was no periosteum left by which such a physiological process could have been effected. Still, the fact remains that a new head, neck, and upper half of the femur had been remade, and for lack of a better explanation the author expressed his belief that this result had been brought about either *directly* by the effusion of new bone-forming material from the small ensheathing casing of new bone which surrounded the lower inch of the dead shaft; or *indirectly* by the catalytic action of this bone forming material upon the reparation matter which the surrounding tissues had found out. For his own part Mr. Bryant was disposed to think that the first explanation was the correct one, for it particularly coincides with a piece of experience he had acquired in dealing with a somewhat similar case some years ago. He brought the case before the Society as a unique one in his knowledge and experience, as a singular example of joint and bone repair under exceptional conditions, as a physiological problem for the Fellows of the Society to solve; and, above all, as a surgical case full of encouragement in the line of conservation, and valuable for future guidance in the treatment of joint and bone disease.—The President referred to the difficulties of arriving at a true explanation of the facts of this case, and thought the bone-forming properties of bone was not sufficiently recognised. He gave two instances which bore on this point, and which supported the view that in these cases bone was formed from the bone ends. In cases where no periosteum remained this was the only solution of the question, unless the new bone was formed by the surrounding tissue.—Mr. Adams considered the case unique. There was no doubt that the upper third of the shaft was regenerated, but whether there is a new head and neck, it is impossible to say. With regard to the formation of new bone, he thought periosteum may have been present, although in an altered condition, and that the subperiosteal tissues were engaged in the production of new bone. — Dr. Crichton Browne agreed with Mr. Adams, and referred to facts observed in skin-grafting in support of this view. — Mr. Pearce Gould inquired whether when the splint was first removed there was free motion in the joint.—Mr. Bryant replied, that no doubt the view that the periosteum originated this new bone was the more probable one and most taking, but (difficult as it was to believe) there was no periosteum left, nor was there any altered or gelatinous periosteum to be seen. He therefore thought that this solution of the difficulty could not be entertained. In reply to Mr. Gould he said the splint had been removed for ten weeks, extension being kept up during that time within the limits of pain; when the splint was removed, rotation, abduction, and adduction were as perfect as now. He still recommended that the limb should be used as little as possible until the new bone had acquired strength.

Dr. Heron showed a male patient, forty-nine years of age, suffering from Ataxic Symptoms with marked knee-phenomenon. There was no history of syphilis; and the man was healthy up to three years ago, when he had severe gastralgia, followed by diarrhœa. Then followed numbness in both hands, and some months later in the toes of both feet, and typical ataxic symptoms developed. Sexual power diminished, and became extinct. Spasmodic twitchings of legs and cramps occurred from April to June last. Since the beginning of 1880 he has had sensation of cord-like constriction around the trunk at two levels. No change in fundus oculi; pupils natural; tactile sensation diminished, especially in fingers; marked incoördination; knee-reflex excessive in both legs, most markedly so in the right; ankle clonus readily elicited, especially on the right side; front tap no response; diminished muscular irritability to both currents in the intrinsic muscles of the hands and in the muscles of the legs and feet. Dr. Heron regarded the case as one of sclerosis of the posterior root-zones of the crossed pyramidal tracts and of portions of the anterior cornua.—Dr. Dowse thought the case anomalous, and alluded to a similar one. He did not think it was locomotor ataxy, although the posterior roots were affected, but as one of chronic transverse myelitis; in which opinion Dr. Crichton Browne concurred.

Dr. Woakes then read a paper "On the Treatment of Goitre by Fluoric Acid," which will be published *in extenso* in our columns.

Reviews and Notices of Books.

Disease of Liver and Portal Vein. Vol. IX. Dr. H. Von Ziemssen's Cyclopædia of Medicine. English translation. London: Sampson Low & Co. 1881.

When Bartolini, in his controversy with Riolanus, wrote his celebrated epitaph on the liver, triumphantly announcing that its dominion was henceforth at an end, the mortuary scroll inscribed on the escutcheon of the deceased organ should have been *Resurgam.* Certainly the physiological investigations of the last quarter of a century have more than restored this organ to its former importance, and the result has been that more attention has been drawn within the last few years to its diseases and derangements by practical physicians than during the whole period that had elapsed since its interment in the middle of the seventeenth century by Bartolini. Thus during the last decade we have Dr. Habershon's Lettsomian Lectures on the pathology and treatment of some of the diseases of this organ, Dr. Murchison's Croonian Lectures on its functional derangements, as well as the second edition of that physician's Clinical Lecture on the diseases generally of that organ. Nor must we omit to mention the valuable observations contributed by the late Dr. Stephen H. Ward, embodying that gentleman's clinical experience, derived from a long connexion as visiting physician to the Seamen's Hospital, an institution which affords a peculiarly rich field for the study of hepatic disease.

The present decade opens with two important works—that by Dr. Wickham Legg on bile, jaundice, and bilious diseases, and that which forms the subject of the present notice. The volume commences with an account of the topography, structure, and function of the liver, deserving of praise from its clearness and brevity. The subject of jaundice is next treated of, and the causes that produce that symptom under various conditions are briefly but lucidly discussed. The author (Ponfick) adheres to the view that the jaundice appearing in phosphorus poisoning belongs to the "hepatogenous" variety, and is to be explained by the swelling of the secreting cells combining with catarrh of the finer ducts to produce obstruction. This is borne out by experimental fact, since in the livers of dogs poisoned by phosphorus the finer ducts within the liver are found always plugged with a colourless mucus, which hinders the descent of the bile. Icterus menstrualis, a peculiar malady first described by Senator, in which the jaundice recurs regularly at intervals of four weeks, is also placed in the same class; the jaundice, however, in this case, he does not attribute to catarrh of the bile-ducts, but to sudden changes produced in the blood-pressure of the portal system. Whether this explanation is the correct one the present state of our knowledge makes it impossible to decide. The influence of menstruation and gestation upon the functions of the liver is a question which ought to be made the subject of experimental research. The connexion between acute yellow atrophy and pregnancy, periodic jaundice and menstruation, and the important observation made by Prout, that in various uterine affections he repeatedly met with a temporary excess of urea in the urine, point to an intimate sympathetic relation between the two organs. Thierfelder contributes a succinct account of the various forms of hepatitis and of acute and simple atrophy of the liver. With respect to the treatment of hepatic abscess we are surprised at the scant references made to the employment of the aspirator either as a means of diagnosis or for relief, nor are the valuable rules laid down by Murchison with regard to the best method of operative procedure under different conditions even alluded to. The same paucity of information with regard to the radical cure of hydatid cysts is also manifest in Heller's article on this subject. Schueppel and Leichtenstein contribute a conscientious but ponderous article on cancer of the liver. The former also writes on the subject of amyloid and fatty degeneration of the liver and diseases of the biliary passages, gall-stones, and diseases of the portal vein. The article on amyloid degeneration contains nothing that is novel, and omits some points of interest, whilst that on diseases of the biliary passages and portal vein is probably the best, as it is the most interesting, article in the work. In conclusion, we would observe that this translation gives the most complete account of diseases of the liver, in their entirety, that we at present possess in the English language, but we qualify this by remarking that that part which deals with the clinical aspect of hepatic affections cannot be compared with Murchison's work in this department, whilst that portion of it which treats of matters of physiological and pathological interest is behind, in respect both of labour and recent information, the exhaustive and able treatise of Dr. Wickham Legg.

Conscious Matter. By W. STEWART DUNCAN. Pp. 128. London: David Bogue. 1881.

THIS small and unpretending, but very suggestive volume, is an attempt to show that the various systems of psychology which are now generally received, including even those of Bain and Herbert Spencer, rest upon an unstable basis, and that the ordinary statements which imply that mind is the antithesis of matter, that all things are resolvable into the subjective and the objective, or into the *ego* and the *non ego*, are wholly and entirely inadmissible. Mr. Duncan maintains that it is much more logical to hold that the physical world is constituted by matter in the dynamical or energetic phase, and that the mental or psychical world is to be regarded as a sentient or feeling phase or property of matter. In working out his views he shows, first, that so late as up to the middle of the present century psychologists held that in man the body was animated or inhabited by a separate soul, but that the tendency of modern thought and inquiry has been to reject the hypothesis of an immaterial soul, and to demonstrate that it is only a property of matter. The point that has been often urged to prove the existence of a separate soul is that no analogy can be shown to exist between mental and physical phenomena. But, as Mr. Duncan pertinently observes, the antithesis between mind and matter is not complete or perfect; it really consists only in opposing matter, or matter *plus* energy, to a property of matter. He observes that the word "physical" has been employed in several senses, sometimes meaning pure dynamics, or the play of forces, sometimes matter apart from either force or feeling, or any quality except mass or extension, and sometimes the two just mentioned in combination, as in the cases of moving bodies. He limits it himself to "force" or "energy." In like manner the term "mind" has been regarded as an *immaterial* substance, capable of feeling and thinking, and also as a certain condition. Now, he goes on to say, it is consistent with clear thinking to contrast one substance with another, as spirit with matter, if there are two substances, or it is consistent to contrast one property with another property, as feeling with consciousness, or consciousness with action. But if it be allowed to contrast one of the properties inhering in a single substance, as mind or feeling, with matter *per se*, then it must be allowed as equally relevant to contrast its companion property, energy, with matter *per se*, in which case it must be further allowed as equally reasonable and consistent to say "dynamics is opposed to matter," as it would be to say "mind is opposed to matter." Instead, then, of "objective" being the true antithesis of "subjective," in the new psychology we should have "active" as its opposite. "What," he asks, "are the two phases or properties inherent in each living man, and therefore in all matter? Is not one a subjective mental, conscious, feeling phase? And is not the other an active, energising, dynamical, physical phase? Where, then, is the use of the term 'objective' or '*non ego*'?"

Mr. Duncan then proceeds to point out that, so far from there being no points of analogy between the physical, as represented by "force," and the mental or psychical, many analogies may be shown to exist between them: as, for example, that they are both destitute of space extension; that they are both related to that which has space extension —to wit, matter; that both have the characteristic diversities that each have, the quality of time, extension, or duration, and so on. He then adduces various reasons for believing that matter is single, and, in fact, is itself only a group of forces, more or less complex, in equilibrium. When this equilibrium is disturbed, the atom or group of forces is alive in the sense of being the seat of momentary feeling, and perhaps even sensation, though it may immediately relapse into unconsciousness. It has, so to speak, its own *ego*. The bodies of the higher animals are made up of a number of such atoms, which are bound together to form a compound or comprehending *ego;* and hence the author arrives at the unlooked-for conclusion—considering that it is the outcome of uncompromising materialism—that if the universe is to be regarded as "an organic whole," as many philosophers admit, there must be an *all-comprehending ego* which represents or is constituted by the synthesis of universal feeling, while the physical aspect of the material universe is, as a whole, the synthesis of universal energy.

Silverlock's Medical Reform Book. Edited by GEORGE BROWN, M.R.C.S. London: H. Silverlock.

WHATEVER value this little volume might otherwise possess is negatived by a very indiscreet attempt to compile a list of "Consulting Physicians and Surgeons, London and Provincial," for the use of general practitioners in times of emergency. This idea is a mischievous one, and the manner in which it is carried out may be inferred from such facts as the following. The List of Consultants in some instances does not include the names of several of the best-known practitioners, and in other instances the best-known writers are omitted.

GEORGE H. PORTER, F.R.C.S.I., has been appointed by his Excellency the Lord Lieutenant a member of the Board of Superintendence of the Dublin Hospitals, in the room of the late Christopher Fleming, M.D.

THE LANCET.

LONDON: SATURDAY, MARCH 12, 1881.

THERE is only too much reason to conclude that the Government have resolved to have no medical men in the Royal Commission for investigating the working of the Medical Acts. With every disposition to believe in the desire of the Government to appoint Commissioners of ability and impartiality for this work, we cannot but fear that in this matter they are taking a course which will satisfy neither the public nor the profession, and which will be very unsatisfactory in its results. Why should the medical profession, as a profession, be excluded from a Commission for considering the working of the Medical Acts? Is the question to be investigated so simple that it can be mastered entirely by lay Commissioners, or is it a rule in appointing Commissioners to exclude from them persons of special knowledge? Both of these questions must be answered in the negative. The existing machinery, or rather nineteen machineries, for diplomatising medical men, are as complex and various as anything could well be. As such they will be hopelessly unintelligible to lay Commissioners. Under these circumstances the lay Commissioners will have to be guided and inspired. By whom? By the Medical Council, which is supposed to have some official monopoly of knowledge and some official right of advising Government on its own efficiency. This is the very way in which Governments have been misled and the question of Medical Reform obstructed for ten years. And it is very difficult to understand how a Commission of laymen only will be able to escape from the delusion that they are to take counsel of the Medical Council, or of one or two ubiquitous members of it who seem to have no occupation so systematic and no pleasure so great as that of opposing the will of the profession. We repeat that a Commission of laymen only will be hopelessly embarrassed by the number and complexity of questions and interests that will have to be considered in connexion with this subject.

Secondly, is it a rule in appointing Commissioners to exclude persons of special knowledge? We do not pretend to much learning in this matter; but we have enough to give a decided negative answer to the question. Two illustrations occur to us at the moment, not to mention others. A Commission exists at present to investigate the rules made by the judges for the working of the Judicature Acts. Surely, this is a subject in which the public are most seriously interested? Of whom is the Commission composed? Entirely of lawyers, either solicitors or barristers! Again, there is at present at work a Royal Commission on Tonnage, one-fourth of which, at least, consists of shipowners. These cases are only two out of a host of instances that we might quote to show that persons of special knowledge are generally included in Commissions. Why should it be otherwise when medical legislation is contemplated — legislation that has reference chiefly to the education and registration of medical men, subjects in regard to which even educated and enlightened laymen are apt to be singularly apathetic and ill informed?

We venture most respectfully to urge on Lord SPENCER and his colleagues that the profession will feel most deeply hurt by excluding its members from this Commission, which may affect for generations the efficiency and the rights of medical men. Even laymen are amazed at the idea of excluding medical men. We grant that members of the Medical Council should be excluded. But there are a dozen men outside of the Medical Council, and sufficiently independent of medical corporations, who could render the most valuable assistance to the Commission, and whose presence in the Commission would be a security to the profession that its feelings and interests were not overlooked. We can only leave the matter with the Government. We repeat our belief that it wishes to do what is right; but we repeat our questions too: What is the hope of lay commissioners understanding the working of nineteen medical corporations, and of a General Medical Council in which they all meet to support and belaud each other? And what is the reason for dealing so exceptionally with the medical profession in constructing a Royal Commission likely so deeply to affect its future?

◆

ON the 7th inst. the Lord Chancellor delivered judgment on the appeal to the House of Lords in the case of the Hampstead Small-pox Hospital. He decided, with the concurrence of the lords sitting with him, that the Metropolitan Asylums Board, the appellants, were not shielded from any consequences of their acts affecting injuriously the private rights of individuals by the Acts of Parliament under which they were created and exercise their functions, any more than if they had been an association of private individuals. The appeal was, therefore, dismissed, and the costs of the proceedings were imposed upon the Board.

Thus ends this lengthy and expensive litigation. The lower Court found, in fact, that the hospital at Hampstead had been conducted so as to become a nuisance to the plaintiffs—in other words, persons occupying houses in the vicinity of the hospital; the highest Court now finds that the legal grounds upon which the Metropolitan Asylums Board sought exemption from certain consequences of its acts are delusive. It is difficult to overrate the important effect the decision of the House of Lords will exercise upon the provision of hospitals for infectious diseases, not only in the metropolis, but also in the country generally. In the metropolis it will confirm the dead-lock which already exists, if it does not lead directly or indirectly to the closure of other hospitals of the Asylums Board, and will paralyse all efforts of that Board with reference to the disease until probably fresh legislation on the subject can be effected—if, indeed, it does not lead to the reorganisation of the Board—a consummation devoutly to be wished. In the provinces the decision will probably give rise to a crop of litigation, and, what will prove a more generally spread evil, will give a plausible excuse to unwilling authorities not to exercise their powers as to hospital provision under the Public Health Act, 1875.

In considering the results of this Hampstead case, it is to be trusted that neither the Legislature nor the public will lose sight of the circumstances which underlie the case, and which have brought about consequences so disastrous to public health administration as concerns sanitary hospitals. It has been too much overlooked during the whole progress of the case, that the original constitution of the Metropolitan Asylums Board rests at the root of the whole matter. This Board was created wholly for Poor Law purposes, the hospitals which it erected and controls were also created for like purposes, and the law under which they were called to act limited them to their Poor Law functions. So far as these functions had relations to public health, it was indirectly in relation to their duties with regard to pauper sickness, and particularly infectious sickness. The Board was placed by the Legislature under the supervision of the Poor Law Board, a Board accustomed to govern itself by the straitest interpretations of law and the practice of routine, and which having in earlier days initiated officially public health administrative reform in England, had afterwards become distinguished by the fatality which had accompanied its association with any public health or sanitary matters. It had signally failed in the one public health piece of administration entrusted to it—namely, public vaccination. It had equally failed in the one sanitary matter for which it was responsible—the sanitary administration of workhouses.

Under these circumstances the Metropolitan Asylums Board infectious disease hospitals were carried out without sufficient regard—if, indeed, any—for the public health considerations involved in them, and they had to be administered and supervised by two bodies, one of which had no knowledge of what was included in such considerations, and the other had proved itself unfitted for them. Hardly had the epidemic of small-pox which began in 1870 manifested itself before the unsuitability of the two public bodies who were entrusted with the charge of the great hospitals which had been erected by the Metropolitan Asylums Board for their task was made manifest, and this curiously enough at Hampstead. Incidents which then occurred at the hospital there, and which should have at once led to investigation, were put aside without investigation, on the plea that it was not within the province either of the Asylums Board or the Poor Law Board; and although both bodies were fully aware of the necessity of investigation under the circumstances, no appeal was made by either for assistance to the department of Government which could have given efficient help in the matter—namely, the Privy Council.

But the Poor Law Board was presently merged into the Local Government Board, and it seemed likely that the Board exercising the functions of both Central Poor Law Authority and Central Public Health Authority in the kingdom would, while the epidemic of 1871–72 was quite fresh in the memory, take steps to ascertain the meaning of the rumours and statements at Hampstead, which even then threatened the consequences which have now happened. But it was otherwise. The Local Government Board gave not the least attention to the matter, and continued to treat the subject, as it has continued to treat it until the last few weeks, as if it were a Poor Law matter solely. The successive public and judicial inquiries as to the Hampstead Hospital failed to arouse it to a true sense of its importance; and so great has been the judicial blindness the Board has displayed, that we are by no means sure that even the disastrous results of the Hampstead case will clear its vision.

It is with the part played by the Local Government Board and the Metropolitan Asylums Board that the Legislature and the public have most concern. The former throughout have failed to recognise the respective parts of Poor Law administration and Public Health administration in the question at issue; the latter have proved themselves utterly unfitted to the combined Poor Law and public health duties which have been thrust upon them in the administration of their hospitals—duties which have been given a sort of legislative sanction in the Poor Law Amendment Act, 1879. As a Poor Law body they would doubtless have performed, and as relates to the Poor Law have probably performed, their work admirably. But when their original duties have been brought into contact with public health considerations, they have failed miserably. It seems to us clear that if the functions of the Asylums Board are to be continued, the Board should undergo reorganisation. The Local Government Board will now have to take up the question of sanitary hospital accommodation in London, and doubtless also in some respects in the provinces, in a different and much wider aspect than it has hitherto considered the subject, and let us hope that they will at least profit by their recent experience.

◆

THE subject of the physique of our soldiers under the present short-service system in the army has been brought prominently forward by Sir FREDERICK ROBERTS in a recent speech at a Mansion House dinner, and has been discussed in an article in the *Nineteenth Century* by Sir GARNET WOLSELEY. Sir FREDERICK ROBERTS complains that our soldiers are too young, and that they are in consequence wanting in discipline, *esprit de corps*, and power of endurance. In support of this view he stated in some detail the result of his observations on the condition of the men who served under him in the Afghan war, and in the justly celebrated march from Cabul to Candahar. He found that the newly arrived drafts, consisting almost entirely of young men, broke down under the continued strain and fatigue which the older and more seasoned soldiers were able successfully to contend against; and from this he argues in favour of reverting to the old system of long service. If it were practicable, there can be no doubt that it would be greatly to the advantage of the army if no recruits were enlisted under twenty-five years of age, when they have attained full growth and development, and if their services were secured for a period of ten years. We should then have an army unexceptionable in point of physique, with powers of endurance, and, if judiciously trained, also with habits of discipline, and *esprit de corps*. But we fear such a state of matters is a consummation to be wished for, but never realised. We believe it would be perfectly impossible to recruit our army under such conditions. Most men at twenty-five have entered upon some course of life, have developed for themselves some line of business, and it would require a much stronger inducement than the pay or social position accorded to soldiers to lead them to exchange for a military career. The greater portion of the men thus joining the army would be the failures of civil life—in too many instances failures from the lack of those qualities and habits which are most desirable in the army. But the question presents itself whether, as this primary constitution of the army appears unattainable, much of the advantage pertaining to it might not be obtained by reverting to the old system of long service—say for twenty-one years; for we do not believe it would be possible to introduce the system of life service again into this country. The quality of the recruits has not deteriorated with the introduction of enlistment for short service; for on comparing the returns of 1865 with those of 1878, we find that in the former, when the minimum period was ten years, the proportion of recruits under twenty years of age was 5488 in every 10,000, while in the latter year, under the existing system, the proportion under twenty was only 4699. Again, looking at weight as a measure of development, the proportion of recruits under 120 lb. was 2597 in 1865, and 1452 in 1878 in every 10,000; so that during the later period the age and development were both more favourable than during the earlier. The falling off complained of therefore must have depended on the removal of the older soldiers to the army of reserve, their places being of necessity supplied by newly raised recruits. The advantage to be gained by reverting to the system of long service would be that the proportion of young men serving in the ranks would be considerably reduced, their places being filled by men of mature age, longer under discipline, and consequently more able to resist the hardships incident to field service, and more likely to be steady and well in hand under discouraging circumstances. But with the question of enlistment for long service arises the very important one of the possibility of maintaining under it an army of reserve. It appears to be a very general feeling that such an army is imperatively required to prevent a recurrence of those scares which have frequently of late years seized the public mind, and that there should be some security against the possibility of being wholly unprepared in case of an attack upon our shores. A good nucleus of such a reserve has been made, and it now becomes an important question in what way it can be maintained with the least interference with the efficiency of our standing army. Mr. CHILDERS proposes to adopt two measures for this purpose: the first being to raise the minimum age on enlistment from eighteen to nineteen years, and the second to increase the period of service with the colours from six to, in most instances, eight years. The first of these measures, while it will reduce by one-fourth the number of immature lads enlisted, will doubtless create some difficulty in raising the requisite number of recruits in the year. We would also caution Mr. CHILDERS that unless some additional precaution, such as the establishment of a minimum weight, be introduced, the rule with regard to age will be systematically broken through, as is well known to be the case under the present rules with lads of seventeen, who invariably, unless when very slight and likely on that account to be rejected, declare themselves to be eighteen years of age. It is true Mr. CHILDERS states "that no man who (though nineteen) has not the physical equivalent of that age will be accepted;" but he has not stated how that is to be gauged; and we fear that unless some definite measure, such as weight, be adopted, the regulation will be of no value. The addition of the two years to the other end of the scale will of course be an advantage, as it will retain men arrived at maturity and well disciplined. We confess we should have been well pleased had Mr. CHILDERS seen his way to revert to the old limited-service period of ten years, but he has stated that in his opinion such a course could not be followed without the adoption of a scale of pensions, "such as no House of Commons could be expected to sanction."

Mr. CHILDERS stated that "no man under twenty years of age, or with less than a year's service, will in any circumstances be sent to India or a tropical station." He does not appear to be aware that this has been the established rule for a good many years past, but that, like many other Horse Guards' regulations, it has been systematically disregarded, as shown by the returns presented to Parliament. If, then, this rule is to be of any practical value, his first care must be to take steps to prevent it being evaded whenever it is found convenient to do so. With a view to meet the complaint of the difficulty of getting good non-commissioned officers, thoroughly up to their work, Mr. CHILDERS proposes to allow them to renew their service with the colours—corporals to the full period of twelve years, and sergeants for a second term of nine years, subject only to the veto of the War Office in each case. He also proposes to improve their condition so much as to make their continuance in the army desirable to them. If in this manner he can secure the services of the best men it will go to some extent at least towards overcoming the difficulty complained of by Sir F. ROBERTS of want of discipline and steadiness, for to good non-commissioned officers much of the efficiency and steadiness of the men is due. We most sincerely trust that Mr. CHILDERS may be successful in his endeavours to improve our standing army, while at the same time he maintains an adequate army of reserve, and that the improvement in the condition of the non-commissioned officers may be such as to lead to the enlistment of a good class of men, who will look forward to promotion and to having an "assured military career" ending with a pension, and with the prospect of Government employment in a civil capacity after their discharge.

NO one who has seen men of different mental calibres and orders of development, of dissimilar types of physical organisation, with natures and personal characteristics barely comparable, exhibiting in their diverse fashions the quality we call "courage," can doubt that this attribute or property of life which we are apt to look upon as a simple virtue, is, in fact, composite in its character, made up of various parts or properties, and that it may spring from either or several of a multitude of causes. The courage of the unreasoning and barely sensate boor who faces a danger of which he is ignorant or unappreciative, is not the courage of the man of culture and high sensibility, who is keenly alive to his peril, and yet dares it. The courage of the hardy mountaineer bears little resemblance to the corresponding quality as exhibited by the pampered and debilitated dweller in cities. Nor is the difference solely one of degree. That strong exercise of the will which enables the man of acute feeling and intelligence to discharge his duty under circumstances of almost overwhelming anxiety, has scarcely anything in common with the stolid immobility of the man who neither feels nor recognises the situation of peril in which fortune has placed him. Nor is the will always the dominant faculty in the physico-mental process by which the result—i.e., conduct characterised as courageous—is produced. Other faculties are often in the ascendancy, and, to use precise terms loosely, organised matter is as often the prime factor as a trained or naturally intelligent and potent mind. In short, what BICHAT says of sleep is true of courage—the general is made up of the particular. One man has courage because he happens to possess a highly developed nervous system gifted with the stability and vigour of health. Another exhibits this quality in consequence of the mature and well-knit development of his muscular system; while a third may triumph over the defects and deficiencies of his "bodily" nature by the force of his mind. There are many forms of courage—mental, nervous, muscular, and, we may even add, visceral—that is to say, courage springing from the excellence and stability of any particular part or system of the being which, for the moment, asserts itself, and, so to say, assumes control. Courage displaces cowardice when the *better* part of a man's nature gains the upper hand, and grasps the reins of conduct; but that better part is not always the mental—or the conscientious will,—it may be, and often is, a relatively ignoble element of the general constitution that comes to the rescue in a critical emergency, so that, if we may paraphrase a truism, the man is saved from being a poltroon as by the skin of his teeth.

Mental courage may take the form of an exceptional effort of the Will, subjugating the turbulent instincts and impulses of fear, and enabling the individual to assume and preserve a bold exterior, while within his whole being is quaking with fear. In one sense this is the highest form of mind-courage triumphing over a weak and shrinking body. Or the mental habit may be such that the consciousness, as it were, inhibits the perceptive faculties so completely that the supreme cerebral centres are not impressed with the keen intelligence of surrounding perils. This is what happens when the mind is so concentrated on the work in hand as to forget its danger. Enthusiasm, passion, revenge, ambition, or a strong sense of devotion, will throw the consciousness into such a mood that it is not harassed by fear, although occasions of fear abundantly powerful to disturb it are present. The danger is there, and the mind is so constituted that it must feel fear, but its attention is arrested and diverted. If it were not for this method of courage-induction, the majority of educated and sensitive men would probably figure as cowards; but the need of personal action or the strong stirring of the emotional nature which occurs—say during an engagement—supersedes and, by diverting the consciousness, suppresses fear. A man of strong passions or relatively weak sensibilities—which amounts to the same thing—can readily establish this mental absorption, which shuts out the impressions of danger, and so appear courageous. The difference between the dogged courage of half-cultured races and the set purpose of highly educated soldiers illustrates this position. The diverse workings of mental courage are, however, so well understood that it is not worth while to dwell upon them. It is the part played by the lower elements of man's nature in the production of valour which we are interested to elucidate.

A courage dependent upon, and arising out of, nervous force, is common, and expresses itself in steadiness of conduct in action without the easily recognised evidences of an overmastering excitement, or even absorbing interest, in what is going on. The nerves not only are under control, but are themselves disciplined; they do not scare the consciousness inopportunely; they do not play it false, or betray it in a moment of urgency. The highest token of power is a self reserve of force, and the integrity of nervous development shows itself in a deep tone of resilience the opposite of the state of irritability, which is, according to the old formula, a disposition to act without the power to act with. The possession of a stable nervous system will often enable an individual who is lacking in will-force or "moral courage" to stand without flinching in the face of deadly danger.

Again, there is a muscular courage due to the excellence of the voluntary system of muscles. It may, at first sight, seem difficult to distinguish this quality from that last indicated, the relations of nerve and muscle being of the closest, when the two are studied under conditions of activity. There is, nevertheless, a sharply defined difference between the two qualities, as viewed from the physiological standpoint. The characteristic property of muscle in a high and healthy degree of development is sustained contractility, or, which does duty for that operation of force, the power of bringing the functions of individual fibres and fasciculi into such coordination that the result may be a steady exercise of power. This steadiness is not the expression of nerve strength, but of muscle strength. Nerve force calls muscular tissue into action, and endows it with motive force, but the *manner* of muscular contraction is more directly dependent on the integrity of muscular development and the excellence of the fibre than the force moving it. Muscular sense or consciousness, automatism and tonicity, are all more directly properties of muscular tissue than of the nerve tissue by, or through, which it is supplied with the energy of action. An apt illustration of these conclusions is found in the difference between two men exposed to the same danger—the one possessed of a strong nervous system, free from the recognised tokens of mobility, the other having a vigorous muscular system in a high state of development. The first will go into action with mental and nervous fortitude, but with a hesitating gait and awkward bearing, with trembling fingers and staggering limbs, while the other, in spite of an even stronger sense of fear, will be steady in his movements. Moreover, the first man is generally pale, the latter either unchanged in colour or slightly reddened, not, however, to any marked extent, face-flushing either indicating vaso-motor depression or an exaltation of cardiac force, the result of passion.

There is also a form of courage which is visceral, or perhaps it would be more correct to say healthy viscera form the physical basis of a state which in its integrity gives rise to an equanimity of temper and a firmness that render the consciousness tranquil and self-protected, and establish a physico-mental condition the reverse of that described by MARSHALL HALL as "the temper disease." It must suffice to sketch the outline of our argument, leaving the scientific memory to fill in the details.

The moral of the view we propound may be pointed in a few brief sentences. It must not be assumed that such "courage" as commanders, or troops, show on the field is of a simple and voluntary character, or is always due to the same cause, still less that it is generally, or even often, the effect of an effort of the Will. The body is not merely the instrument of the mind, but an integral part of the mind itself, if not practically its base and centre. Sometimes one part of the nature and sometimes another is in the ascendancy. Individuals vary with their own states of health and "feeling," and with the circumstances by which they are surrounded. There are also radical differences of physico-mental constitution whence spring great and contradictory differences of nature and character. Courage is quite as much a result of mental and physical training as of congenital qualities. Healthy development, and health as a state, are essential to courageous acts and bearing. Meanwhile general inferences as to courage and generalised methods of producing it, are certain to fail in individual instances, because while one man may evolve courage as an effort of the will, another, though equally strong-minded, cannot appear courageous because his nervous, or muscular, or visceral system is not in a condition to contribute its quota to the general result. The history of heroism in different ages, read in the light of development and with regard to the domestic and general habits of the people, will be found to supply food for reflection of the highest suggestive nature. It will teach lessons which it would be well to lay to heart in any reorganisation to which our army may hereafter be subjected. The time has not arrived when the physiologist and the psychologist are deemed worthy to have a voice in councils of State; but in relation to matters involving questions of *development* it is strange that the obvious teachings of science should be entirely disregarded or set aside. Experience may have heaped together large stores of information; but there are branches of knowledge which only science can supply.

◆

OUR knowledge concerning the source of the liquor amnii is somewhat uncertain, and two theories are held with regard to it. The first is that it is the product of the secretion or transudation from the maternal vessels in the uterus; the other, that it is the product of the secretions of the fœtus. Accurate knowledge upon this subject is of very great importance, for its elucidation lies at the foundation of the pathology of some of the diseases of pregnancy and intra-uterine life, and involves the whole question of the activity of the kidneys in the fœtal state. Experiments have been made upon pregnant animals with a view to solving the problem, and the most recent are those conducted by WIENER in Breslau, the results of which are published in a paper in the *Archiv für Gynækologie.*

Two or three kinds of experiments have been performed. In the first, a solution of sulph-indigotate of soda was introduced into the jugular vein of rabbits in an advanced state of pregnancy, and the animals killed at intervals ranging from a quarter of an hour to two hours and a half after the injection was made. It was then found that the liquor amnii in all the cases contained the colouring material used, its presence being proved by the microscope. In none of the cases was the colouring material found in the organs of the fœtus, with the exception of the stomach and intestines, into which it had obtained admission by the process of swallowing; none appeared to have passed by the fœtal kidneys. The quantity of the material found in the liquor amnii was small, and this appeared to be due to its elimination by the maternal kidneys. To obviate this the kidneys were extirpated before the injection was made, and in cases thus treated a large quantity of it passed into the amniotic fluid. When animals in the early stage of pregnancy were similarly treated, hardly a trace of colouring matter was found in the liquor amnii. To decide what part the fœtus plays in the production of the liquor amnii, the colouring material was introduced into the body of the fœtus. A quantity of the coloured solution was injected into the amniotic sac and the fœtus made to swallow, but it was found that the material did not in this way enter the blood of the fœtus. It was then injected under the skin of the back of the fœtus. On subsequent examination, the colouring material was found in the kidneys of the fœtus in precisely the same situation as it was found in those of the mothers in the first series of experiments. It was traced there as soon as twenty-five minutes after the injection, and in one case a drop of coloured urine was discovered in the bladder. In these experiments, moreover, the liquor amnii was coloured blue.

From these data WIENER argues that the fœtal kidneys are not only active during fœtal life, but that they secrete rapidly, and are the chief source of the liquor amnii. He maintains, moreover, that during early life the fluid comes exclusively from the embryo until the fœtal membranes come into intimate contact with the maternal tissues, and the placenta is formed. At first the fluid is derived from the cutaneous vessels of the fœtus, afterwards from the Wolffian body, and later from the kidneys. After the membranes have come into intimate connexion with the uterus, a portion of the fluid comes from the maternal vessels. WIENER explains the varying results of chemical analysis of the liquor amnii, and the occasional absence of urea in it, by the statement that the urea in it continuously undergoes decomposition or diffusion into the maternal blood.

Besides the experiments referred to, other evidence bearing upon the question is brought forward and discussed, especially that furnished by cases in which occlusion of the urinary passages had occurred during fœtal life. In these cases considerable quantities of urine have been found behind the occlusion, the secretion of which, according to FEHLING, is pathological. This opinion of FEHLING is, in our opinion, successfully controverted by WIENER. It cannot be questioned after the evidence brought forward, that both the maternal vessels of the uterus and the secreting organs of the fœtus contribute to the production of the amniotic fluid, but the proportion the contributions of each bear to one another cannot be regarded as finally settled. The evidence adduced by WIENER in favour of the fœtal kidneys being the chief source, although indirect in its character, goes far to prove his view; but until further and more conclusive evidence is adduced we cannot go beyond the statement that the liquor amnii is the joint produce of the vessels of the uterus and of the fœtal kidneys.

AT a meeting held at Chelmsford for the purpose of promoting the establishment of a cottage hospital in the town, Dr. Vipan stated that out of 260 cottage hospitals which had been founded in Great Britain, only eight had failed, and those not from want of funds, but on account of theological disputes between members of rival sects.

Annotations.

"Ne quid nimis."

DEATHS FROM CHLOROFORM.

TWO instances of death from chloroform have been recorded during the past week. One occurred at Swansea. The wife of a commercial traveller, aged nineteen, was undergoing an operation for a uterine tumour. Death occurred after the influence of the anæsthesia had been maintained for an hour and three-quarters. It is very desirable that the details of the case should be published, since it is unusual for chloroform to be fatal so long after the commencement of its administration. The other case, which occurred at the Bradford Eye and Ear Hospital, was of a more ordinary character, inasmuch as death occurred just as the patient was getting under the full influence of the anæsthetic. The patient was a man, aged sixty, who was about to be operated on for cataract, and he had been run over and slightly injured about a fortnight before—a fact which was not known to the surgeons until after his death. Mr. Denby appears, from the account of the inquest, to have administered the chloroform on a towel, a small quantity of brandy having been previously given. Apparently a drachm of chloroform was first administered: the patient was still for two minutes, and then struggled for two minutes more, and then again became quiet. Another drachm of chloroform was poured upon the towel, but part of it was spilt. After the second dose had been administered for about a minute and a half, it was noticed that the face became pale. Mr. Denby asked Dr. Bell, who was holding the pulse, how the pulse was, and he said that it had suddenly ceased. The heart was found to have ceased beating, and all efforts to restore animation were fruitless. The circumstances of the case were thus of the usual character. The accident was ascribed to heart disease by the verdict of the coroner's jury, but the fact does not appear to have been established by post-mortem examination. With regard to these and all other deaths from chloroform, unavoidable under the circumstances as they doubtless are, the question arises, Were they altogether unavoidable? Would the patients have died had ether been used instead of chloroform? This is a question to which a positive answer cannot be given; but since it is certain that the proportion of deaths from ether is far fewer than from chloroform, it is probable, in the same degree, that any given death from chloroform would not have occurred had ether been given instead. No surgeon, who sanctions the administration of chloroform instead of ether, can acquit himself of some measure of responsibility for the death of his patient, unless he can prove that the special circumstances of the case rendered it, for the patient's sake, desirable that the increased risk, if small, yet measurable, should be run, and no other consideration should be held to justify the employment of chloroform.

FILTHY FOOD.

THE Birmingham sausage case, to which attention is drawn by one of our correspondents in another column, opens up a very wide and important question, and one which we have frequently discussed before. The population of this country being ahead of its powers of production, the people are driven, to a very considerable extent, to the consumption of preserved and tinned viands of various kinds. We have often pointed out the necessity of *every* tin or packet of preserved provisions bearing a label setting forth the exact nature of its contents, and until this is done it can hardly be possible that persons can be convicted of cheating and adulteration, or that the many opportunities of dishonesty which now exist will not be taken full advantage of. The Birmingham sausage-monger was convicted of putting in his sausages material which was not fit for human consumption owing to its putridity. This is a statutable offence, and we are glad that the offender was sent to prison without the option of paying a fine. It is doubtful, however, whether he could have been punished for putting horseflesh into his sausages. A "sausage" is a thing of acknowledged variability of constitution, and possibly a beef sausage might still be regarded as such, even though the beef bore but an infinitesimal proportion to the "flavouring." The same remarks apply to the various "potted meats," "preserved milks," "patent foods," &c. The public ought to be protected, and it is certainly proper that the percentage compositions of manufactured articles of consumption should be affixed to their containing vessels and papers. Of potted meats we need say nothing, except that respectable firms ought to be glad to protect themselves voluntarily by a percentage composition label. We think the exact amount of sugar, or other preservative, in every tin of condensed milk, should be stated; and we think it is high time, to take only one example, that the State should cease to help in the gulling of the public by allowing a pennyworth of lentil-meal to be sold for three-and-sixpence. It is becoming a question also whether manufacturers and importers of preserved and cured foods should not be placed under the Excise laws. At all events, it seems absolutely necessary that inspectors, similar to excisemen, should have right of entry into the premises of manufacturers of sausages and potted meats, for it was only by a happy accident that the Birmingham fraud was discovered. Inspectors of imported foods, whether tinned or preserved, seem also a crying necessity, in the face of what we may call the trichinosis scare and the Welbeck bacilli.

CINCHONA CULTIVATION IN CEYLON AND JAMAICA.

THE estimate of the cinchona cultivation in Ceylon, which we quoted in our issue of Jan. 29th in a review of Mr. Markham's recent work, is fully confirmed by a writer in the *Colombo Observer*, who states that the number of cinchona trees planted in the island in 1880 was not less than twenty millions. It is computed that, allowing for failures, these trees, together with those planted in previous years, will yield by 1885 not less than ten million pounds of dry bark a year, and, assuming other sources to be equally productive, the supply will then exceed that at present available by at least the above amount. The question is asked, "Will the demand equal the supply, or will the bark become unsaleable except at unremunerative prices?" That the price of cinchona bark will fall seems highly probable, and, in the interest of humanity, it is greatly to be desired that it should fall; but it cannot be doubted that the consumption will vastly increase with reduced prices, and it is not likely that the supply will exceed the demand to such an extent as to render the culture unremunerative.

It is not alone from the East that the plant is being successfully cultivated. A very encouraging account has been received from Jamaica, where the Government is wisely taking every means for extending the cultivation. We have before us a number of the *Jamaica Gazette* containing an advertisement offering the supply, from the public gardens, of cinchona seed—of crown bark at 5*s.* per oz., and of red bark at 3*s.* per oz. An ounce of seed will, it is estimated, produce 20,000 seedlings, which, if carefully raised, will plant five acres of land. Or young plants are offered, ready for transplanting into nurseries, at 21*s.* per box of from three to four thousand. Mr. D. Morris, Director of Public Gardens and Plantations in Jamaica, has also issued a broadsheet containing hints and suggestions for raising the plants from seed, and establishing cinchona plantations. He points out the various elevations at which the cultivation of the different species of bark may be most advantageously carried on, and the kind of soil which suits them best. It is very probable that vast tracts of land hitherto lying uncultivated on the northern slopes of the Blue Mountain range will prove suitable for the plants. The Government plantations already furnish bark to the London market, which fetches a good price. The sale of one consignment in August last, amounting to about 6000 lb., realised £1300. During the year 1879–80 no less than 27,399 lb. have been shipped. It is interesting to observe that the average price of both Jamaica and Ceylon bark was higher than that of the South American specimens, showing that the valuable properties of the trees are much improved under cultivation. The highest price of the Jamaica bark is a little in advance of the highest price of the same kind of bark grown in Ceylon. The similarity of climate in the two islands is shown by their long rivalry in the production of coffee, and it seems likely that a similar rivalry will occur in the growth of cinchona. Ceylon at present has the start, but it is hoped that as large tracts of land and the necessary labour are now available in Jamaica, the requisite capital and energy to overcome the initial difficulties of the enterprise will not be wanting.

The competition of the East and West Indies is stimulating the South American exporters to renewed action. "The result is," says Messrs. Rucker and Bencraft in their last monthly circular, "that hitherto untouched forests have been attacked, new ranges of mountains have been explored and tapped, and we are threatened with supplies of considerable magnitude from new sources." About 4000 packages of a new bark have already been placed in the market. It comes from the United States of Columbia, and is described as being of a somewhat peculiar character, although of fair quality. It yields about 2 per cent. of quinine. It is said by a well-known authority not to be the product of any species of cinchona tree. Very strong evidence will be required to prove the startling fact that any other than cinchona bark will yield quinine.

NEUROPATHIC EMPHYSEMA.

DR. BROWN-SÉQUARD exhibited at a recent meeting of the Société de Biologie the lungs and heart of a dog which he had killed a few hours before by suddenly crushing its head. Extreme emphysema of the lungs had been instantly produced. During the last ten years he has repeatedly observed that the mechanical stimulation of the base of the brain is much more energetic than is galvanic excitation as a means of producing certain inhibitory phenomena and effects on the vaso-motor nervous system. He has shown that faradisation of the pneumogastrics always causes emphysema of the lungs in the dog, the cat, the rabbit, and the guinea-pig, evidently by causing contraction of the smaller bronchial tubes, which drives the air with sufficient force into the pulmonary vesicles to rupture them. He has also shown that this emphysema may be produced equally well when the thorax is open if the trachea is ligatured. But in these experiments the emphysema produced is slight compared with that which is caused by mechanical excitation of the medulla when it is suddenly crushed. A guinea-pig was also exhibited in which there was no emphysema, although the medulla had been crushed, because the pneumogastrics had been previously divided. In other experiments, in animals of different species, the spinal cord was first divided at the level of the third or fourth pairs of cervical nerves, and the destruction of the brain caused emphysema just as if the spinal cord had been intact. Dr. Brown-Séquard took the opportunity of pointing out that the mechanical stimulation of the brain, when it is suddenly crushed, produces effects which are not only more considerable than those caused by galvanisation of the medulla and other parts of the brain, but also effects which differ from those which can be caused by electricity. One of these is the inhibition of the heart, which is in general such that it is not followed by any return of activity. Another result is the production of abundant pulmonary and bronchial hæmorrhages. There is also an almost complete inhibition of spinal reflex action in the cervico-dorsal region, and an extreme augmentation of this action in the dorso-lumbar region.

REDUCTIO AD ABSURDUM.

AN inquest held on the 4th instant at Stamshaw, near Portsmouth, illustrates the occasional inutility of a coroner's inquest for determining the cause of death. It seems that a dairyman named Stallard, aged fifty-six, who had sometimes suffered from cough, after doing his daily work went to bed well, and died in the night with symptoms of asphyxia. Mr. Ford of Portsmouth, who was called to the deceased, gave evidence at the inquest, and in answer to questions from the coroner as to the probable cause of death, replied: "I am unable to say; the man was well up to the day of his death, and the winter cough was not enough to account for his death." The coroner: "I don't ask you what was the actual cause of death, but the probable cause." Mr. Ford: "I am unable to say." After some altercation between Mr. Ford and the coroner, the former was permitted to withdraw. The coroner, in summing up, said that if the jury wished it he would order a post-mortem examination. A juryman asked "if the coroner, with his fifteen years' experience, would not give the probable cause of death," and the coroner replied that, although he might, he did not think it was his duty to do so. The jury then returned a verdict of "Death from natural causes." One of the jury suggested that "Mr. Ford should be censured," and this sentiment was echoed by several. Another juror asked the coroner if Mr. Ford would receive the fee. The coroner said that that was a question which would remain for his future consideration.

There is no doubt that in this case Mr. Ford was wholly in the right, and the coroner wholly in the wrong, for there was not a particle of evidence as to the cause of the deceased's sudden asphyxia. Popular opinion is always ignorantly opposed to a post-mortem examination, but that it was really necessary in this case there can be no doubt. If a post-mortem were not necessary no inquest was necessary, and we could almost wish that the coroner would withhold Mr. Ford's fee for evidence in order that the matter might be brought before a higher tribunal.

INFLUENCE OF HEREDITY ON THE TRANSMISSION OF LESIONS.

M. MASOIN has lately been investigating the heredity of certain lesions, and has published his results in the *Bulletin de l'Académie Royale de Belgique*. He has excised the spleen in several generations of rabbits, and made them couple. He then compares the relative weight of the spleen to the body at large. In healthy rabbits the average proportion of the spleen to the body is 0·1028 to 100, and never descends lower than to 0·0645 to 100. Now he finds that in the rabbits of the first generation the spleen has not disappeared, but that it has become atrophied, the proportion being 0·0549 to 100, the latter number being taken as representing the total weight of the body. It is obvious, then, that it has undergone considerable diminution in size. It might be expected that the members of the second generation of rabbits in which the ablation of the spleen had been effected would present a still smaller and more atrophied organ, but this is not so, for the diminution, though well marked, remains the same as in the first generation. M. Masoin has also investigated the influence of digestion on the turgescence of the spleen. He has satisfied himself that a moderate meal does not occasion swelling of the organ, whilst, if a large supply of food be taken, as in a famished animal, it undergoes considerable enlargement. In common with various other observers, he finds that it attains its maximum volume about five hours after the ingestion of food. When the spleen is completely removed it does not undergo reproduction, nor has he noticed the enlargement of the lymphatic glands observed by so many authors to occur consecutively to the operation.

DR. PIROGOW.

AT a recent meeting of the Society of Medical Practitioners of St. Petersburg, M. Berthenson, in view of the approaching jubilee of Dr. Pirogow, gave an account of that distinguished surgeon's life. It would appear that in 1828 M. Pirogow, having passed through the course of medicine at Moscow, went to Dorpat to complete his studies. Five years after he graduated there as Doctor in Medicine. It was then proposed to him to take the chair of Surgery in the University of Moscow; but he was prevented from accepting this offer by a long and painful illness. After his recovery, the Moscow chair having been filled up, he was placed in the chair of Surgery of the University of Dorpat, which was regarded as a great distinction. The beginning of his special celebrity dates, however, from the year 1840, when he was requested to organise the clinical teaching in the hospitals of St. Petersburg. He accepted the task, entered upon it with much enthusiasm, and carried it to a successful issue. When the war in the Crimea broke out he was placed at the head of the Russian military medical service in the field, and rendered inestimable services to his country. After the war Dr. Pirogow became curator of the Academic Circonscription of Odessa, and subsequently of Kiew. In his new position he proved himself an ardent partisan of university autonomy, and sought to cultivate closer relations between the professors and students. In 1870 Dr. Pirogow laid the foundations for the services rendered by the Russian Red Cross Society in the Franco-German war; and during the late Russo-Turkish war he acted as guide and counsellor of the sanitary service of the war.

UNQUALIFIED PRACTITIONERS AND PRIVATE DISPENSARIES.

THE death of another person attended by an unqualified medical practitioner, attached to a dispensary in Church-street, Edgware-road, belonging to Mr. Kisch, has been the subject of a coroner's inquiry. Dr. Hardwicke very strongly expressed himself on the subject, but not, we think, too strongly. The death of a young girl of nineteen, without the benefit of regular medical advice, though that advice had been sought for in the regular way, is a public scandal. Mr. Kisch explained that he generally attended cases himself, but had failed here in consequence of illness. He would, however, have cleared himself much more effectually from his great responsibility if he had explained why, in his absence, he could not get a medically qualified friend to see a patient so ill. Further, it would have been satisfactory if he had stated the relation of his residence to the dispensary, and the distance between the two places. Practically the impression is left that patients at this dispensary are under the care of an unqualified practitioner, and the public will be apt to agree with Dr. Hardwicke that "the system of private dispensaries with unqualified medical men is vicious, and ought to be discountenanced in every way."

A CASE OF MOVABLE LIVER.

IN the *Wiener Med. Blätt.* is recorded an observation accidentally made on a physician by Dr. Chvostek. There were no symptoms whatever of anything wrong in the abdomen, and there was no history of violence or of any occurrence that threw light upon the condition. When the man stood up, the upper and posterior border of the liver was felt to come forward from under the margin of the thorax, and to be six centimetres and a half below the tip of the xiphoid cartilage in the right parasternal line, and one centimetre below that point in the left parasternal line. The left end of the liver was plainly felt through the abdominal wall, and from it the anterior, or rather the lower edge of the liver could be traced arching down to the right, being in the middle line fifteen centimetres below the xiphoid process, and in the right nipple and axillary lines respectively seven and one-and-a-half to two centimetres below the edge of the thorax. The liver did not markedly descend on taking a deep inspiration. In the horizontal posture it could be replaced under the ribs to a considerable extent. In lying on one side the organ fell to some extent towards the dependent side. The lower edge of the suspensory ligament could be felt tightly stretched, but this produced no pain, and so completely absent were all symptoms that the condition was only discovered accidentally.

MEDICAL SOCIETY OF LONDON.

THE dinner to commemorate the 108th anniversary of the Medical Society of London was held at the Criterion, on Tuesday, March 8th, the President, Mr. Gant, presided. He was supported by the Presidents of the Royal College of Physicians, the Royal College of Surgeons, the Obstetrical and Hunterian Societies, Major Duncan, and about eighty Fellows of the Society. In responding to the toast of the learned Societies, Dr. Matthews Duncan pointed out the danger of the formal debates now so popular overshadowing the more valuable original papers read at the ordinary meetings of the Societies, one page of which was often of more worth than a whole volume of discussion. The two silver medals of the Society were presented, one to Sir Joseph Fayrer for his paper on Hepatic Abscess, the other to the Senior Honorary Secretary, Mr. D. H. Goodsall. Instrumental and vocal music was excellently rendered by Drs. Althaus and P. Boulton.

ABUSE OF MEDICAL CHARITY IN BELFAST.

A REPORT of a Committee of the Ulster Medical Society is before us on the Abuse of Medical Charities, from which it would appear that many persons for whom the medical charities of Belfast are not intended avail themselves of the advantages of the various institutions, to the injury of the persons themselves and of the medical profession. This evil, the Committee reports, exists to the greatest extent in the out-door department of the several hospitals. No facts are given in illustration of these views, but supervision and investigation are recommended. We would strongly support the recommendation. The evil is an undoubted one, but the examination of it should be so careful as to carry conviction to those even who believe in nothing but old and free kinds of charity. The eighth proposition of the Ulster Medical Society's Committee will rather surprise by its very obviousness, "That we disapprove of any member of the hospital staff receiving fees for services rendered to any patient whilst under hospital treatment." If the abuse of hospitals be such as the Committee states it to be, it may seem hard on the medical staff not to exact fees from patients who can afford to pay; but clearly they should raise objections to them as hospital patients, and refer them back to their own medical advisers.

UNQUALIFIED MEDICAL PRACTITIONERS.

WE have before us a very excellent paper on the great evil of practice by unqualified persons in this country. The author, Mr. David Edgar Flinn, treats the subject both ably and gravely. He thinks the evil not only great but increasing. As medical officer of health for the Brownhills Urban Sanitary Authority, he testifies that over one-fourth of the individuals whose deaths are registered are attended by unqualified persons. His great complaint is that regularly qualified medical men are associated with these unqualified persons; that sometimes a partnership is entered into; sometimes the use of the name of the qualified man is allowed; and sometimes, even, a medical practitioner sells his practice to an unqualified man. These are facts within the knowledge of Mr. Flinn, and they call for very serious consideration. He alleges that medical men act so often with a view to the annoyance or injury of a brother practitioner. He advocates the establishment of Medico-Ethical Societies for holding up and holding high those principles of honour and dignity which have always been dear to the profession, and which no medical man can violate without injury to both himself and his profession. We entirely agree with him when he says "it is the duty of all medical men to study the ethical and moral laws regulating their profession."

"THE MEDICAL DIGEST."

WE are glad to learn that Dr. Neale is preparing a new edition of his valuable "Medical Digest," published originally by the New Sydenham Society five years ago. It is intended to bring the work up to the end of the present year, and it will then contain over one hundred thousand references to original and editorial articles that have appeared in THE LANCET, and other medical journals, during the past thirty years. In its new form we should hope that the work will be more generally appreciated. Hitherto its value has been recognised by comparatively few persons; and when issued without the restrictions necessarily imposed upon publication by a Society, it will no doubt appeal to a large, and perhaps more discriminating circle of readers.

WESTMINSTER HOSPITAL.

THE lectures on Systematic Surgery and Practical Surgery, at Westminster Hospital, have up to the present been delivered on alternate years and conjointly by Mr. Cowell and Mr. R. Davy. For the future the two courses are to be given each year, and Mr. R. Davy is appointed sole lecturer on Practical Surgery and Minor Surgery, while Mr. C. Macnamara is to be Mr. Cowell's colleague in the chair of Systematic Surgery.

AT the distribution of prizes to the students of the Punjab Medical College on Nov. 20th, two or three matters of interest were mentioned by Surgeon-Major E. Burton Brown, the Principal. In memory of the late Dr. Neil, 1200 rupees have, it appears, been collected by his pupils, the interest of which is to be devoted to the purchase of two silver medals, to be called the Neil Memorial Medals, to be awarded to the students who pass the best examination in anatomy and surgery respectively. Dr. Brown also announced that the Nawab of Bahawulpur had presented to the medical school the liberal sum of 10,000 rupees to form a fund to provide scholarships to be called the "Grey-Bahawulpur," in honour of Major Grey, the late political agent of that district. It is satisfactory to note the interest taken in the school by the Lieutenant-Governor of the Punjab, Sir R. Egerton, who presided at the distribution, and whose remarks on the occasion were warmly appreciative of the value of medical studies.

A LARGE and influential meeting, presided over by Mr. Cæsar Hawkins, was held in the board-room of St. George's Hospital last week, at which many of the medical and surgical staff of the hospital and the old pupils and friends of Mr. G. D. Pollock were present, and at which it was resolved —"That a scholarship be endowed in connexion with the Medical School of St. George's Hospital as a testimonial of respect and regard of the associates, pupils, and friends of the Mr. Pollock, on his retirement from the position of surgeon to the hospital, and that the said testimonial be called 'the George Pollock Scholarship,' the professional and other friends of Mr. Pollock being invited to subscribe."

WE are informed by Mr. Pearson Hill, the prime mover in the proceedings against the Metropolitan Asylums Board *in re* the Hampstead Small-pox Hospital, that his costs will amount to between four and five thousand pounds. The costs on the other side cannot be much less than double that sum. As no provision was made in the Act of Parliament, under which the Asylums Board was constituted, for the defraying of expenses incurred in litigation, it is a pressing question whether the costs in the proceedings just concluded can be charged to the ratepayers.

A RUMOUR has been widely circulated of late to the effect that Professor W. T. Gairdner intends standing as a candidate for the Chair of Pathology in Edinburgh University. We are glad to be able to state, on excellent authority, that there is not the slightest foundation for this rumour—fortunately for Glasgow.

THE President and Council of the Faculty of Physicians and Surgeons of Glasgow have appointed Mr. David McVail, M.B., Lecturer on Medicine in the Glasgow Western Medical School, to be the next Faculty Lecturer. His subject will be "The Physiology and Pathology of Respiration."

AN investigation by the guardians into what appears to have been a frivolous charge against Mr. Henry Grace, medical officer of the Bristol Workhouse, has resulted in the passing of a vote of confidence in their medical officer by the board, who "desire to express their full confidence in his skill, attention, and ability."

THE Secretary of State for War has appointed Onslow Robert Richmond, Esq., M.R.C.S.E., L.R.C.P.L., to be Assistant Visiting Surgeon for Gravesend, under the Contagious Diseases Acts, 1866 to 1869.

THE *London Gazette* of Tuesday announces the nomination of Dr. Alfred Henry McClintock of Dublin to be, for five years, a Member of the General Council of Medical Education and Registration, in place of Dr. Alfred Hudson.

ROYAL LONDON OPHTHALMIC HOSPITAL. — The annual meeting of the governors of this hospital was held on Tuesday, when the report read represented the financial condition of the institution as satisfactory. The subscriptions of the past year had nearly equalled those of the preceding year; whilst the donations, on the contrary, exhibited a falling off. Various additions to the internal arrangements of the hospital had been made, and the medical tuition had been rendered more complete by the establishment of classes for the special study of the anatomy of eye diseases.

AN election for a physician to the Hospital for Incurables, Dublin, in the vacancy caused by the decease of Dr. Peele, will be held on the 17th inst. There are a good many applicants for the post, the emolument of which is sixty guineas per annum.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bristol (*City and County*).—Mr. Davies reports a death-rate of 20·0 per 1000 population during the year 1880, and expresses the opinion that the sanitary condition of the city, as indicated by the returns of mortality, had not been unsatisfactory, either in comparison with the returns of former years, or with those of other large centres of population. The returns, however, show "a very wasteful destruction of infant life," of which a great part, Mr. Davies thinks, is "clearly attributable to ignorance and neglect." Scarlet fever is the chief subject of comment both in Mr. Davies' annual summary and his report for the fourth quarter of 1880. He confesses his inability to deal effectually with the disease armed only with the powers sanitary authorities at present possess, and he considers that we ought to make some sacrifice of our ideas of personal liberty to arrest its ravages. He suggests that—1st. It should be made compulsory on the landlord of every house with a case of scarlet fever in it to send notice of the case to the sanitary authority. 2nd. That the sanitary authority should, on receipt of such notice, offer hospital accommodation for the patient or patients at a reasonable rate of payment, at a hospital provided by the sanitary authority. 3rd. That in case of refusal of removal of such patient by the parents, guardians, or friends, notice in the form of a caution to the public should be attached to a prominent part of such house or premises, showing that the house is infected with scarlet fever. 4th. That all ingress and egress to and from such houses should be regulated by rules made by the sanitary authority, and approved by the Secretary of State. 5th. That in case of the removal of a patient into hospital for isolation, the parents or guardians of the patient should have the power to appoint the medical attendant of the patient, if they do not wish to avail themselves of the services of the ordinary medical attendant.

Bradford (*Yorks*).—Mr. Butterfield, in his report for the fourth quarter of 1880, returns an average annual birth-rate equal to 33·1 per 1000 population, and an average annual death-rate equal to 20·5. The most prevalent zymotic disease during the quarter was scarlet fever, and it appears that the number of cases sent into the fever hospital was greater than during any previous epidemic. Mr. Butterfield has the following observations on the hospital:—"The large district in which the hospital is situated, and in which are included the deaths which occurred in that institution, shows a lower mortality from this disease than Bowling. It is a fact well known to all who have had experience of fever hospitals that the removal of scarlet fever patients from the close and confined air of an ordinary bedroom to the airy and well-ventilated wards of a hospital is in itself a very powerful remedy. There are few diseases which require for their proper management more copious supplies of fresh air than scarlet fever, and yet it is not at all uncommon to find cases of this disease boxed up in rooms from which fresh air is excluded as if it were something pernicious and deadly. While the patient is made to breathe and rebreathe a poisoned atmosphere, slightly flavoured with carbolic acid or chloride of lime, reliance is placed on drugs, which are rarely useful and often mischievous, rather than on perfect cleanliness and abundant ventilation."

Peterborough (*Rural*).—Mr. Sinclair Thomson estimates the population of the district at 22,300, and gives the death-rate for 1880 at 15·2 per 1000 inhabitants. Outbreaks of scarlet fever and of measles seem to have been the principal sickness events of the year, nevertheless the "wooden hospital" of the rural sanitary authority does not seem to have been used. A local outbreak of enteric fever in one village shows the existence in connexion with the disease of states of insufficient drainage and neglect of privies too common in rural districts, but which were here amended *after* the outbreak. Mr. Thomson has the following observations on excrement nuisances:—"The prevention of excrement nuisances in our villages and rural districts, where there is no regular system, is a subject demanding serious consideration. I believe the water-carriage system is rarely suitable for country districts, because the sewage can only be properly dealt with where there exists a good supply of water, a good sewer, and some arrangements for rendering the sewage harmless at its outfall. Where the water for flushing has to be brought by hand I have frequently found the pan very foul, the seat wet, and the syphon pipe blocked. It is desirable that houses in the country should be provided with dry earth or ash-closets."

Tamworth.—Dr. Herbert J. Fausset reports for the year 1880 a death-rate of 22·0 per 1000 inhabitants in this borough. It is obvious from his report that the Sanitary Authority is by no means as careful in the performance of its duties as it should be, and that indications of sanitary negligence abound in the municipal district. A curious instance of the perverse administration of the authority is afforded by the fact that, in 1876, with the view of diminishing the nuisance from midden-privies in the town, 227 pail-privies were introduced on the Rochdale system, and that these are so mismanaged as to have become as great nuisances as the midden-privies. Dr. Fausset writes of "the continuous cropping up of cases of typhoid fever," and of "the present alarming outbreak" of that disease, and states that the outbreak must be ascribed to impure water, defective drains, and inefficient and careless removal of excremental filth.

Brentford.—Mr. J. Williams reports for 1880 a birth-rate of 38·9 per 1000 inhabitants, and a death-rate of 17·47 per 1000.

Coventry.—Dr. Mark A. Fenton reports a death-rate in this urban district of 21·1 per 1000 inhabitants, and a birth-rate of 32·3. The death-rates for the decade ending 1870, and for the decade ending 1880, were stationary (21·0), and upon this Dr. Fenton observes it "would appear to prove that the application of the Public Health Act has been followed by no beneficial results." But it must first be shown that a stationary death-rate in the particular circumstances is not equivalent to an improvement, and this is not done. The morbid event calling for chief consideration during the year was infantile diarrhœa. An epidemic of that malady in the months of August and September is described as disastrous. Dr. Fenton made an inquiry into every fatal case, and his results may be summed up in the statement of improper feeding concurring with high temperature, and in half the cases an atmosphere polluted with accumulations of filth.

Hereford (*City and County*).—Dr. Vavasour Sandford is able to write of progressive improvement throughout his district in 1880, a marked decrease in the rate of mortality in each of his sanitary districts, "proving the benefit derived by all classes in this county from the Public Health Act being enforced." Dr. Sandford holds that "public schools are the *hotbeds* [of infectious diseases], and ever will remain so, until the Legislature enforces the timely information to the medical officers of health that infection exists in a house or family."

Sittingbourne (*Urban*).—Mr. H. G. Sutton reports scarlet fever as exceedingly prevalent in 1880, and expresses the opinion that until we have compulsory registration of infectious diseases our efforts to deal with this disease and measles must be foiled. He writes of a "spacious" infectious disease hospital for the district being in progress of erection. Infantile diarrhœa was very fatal during the high temperature of the month of August. The temperature facilitated the fermentation and decomposition of the food, often unsuitable, given to infants, and Mr. Sutton thinks that ladies might do much good in instructing the mothers among the labouring classes in preparing infants' food properly. The death-rate for the year was 16·3 per 1000 inhabitants.

Sittingbourne (*Rural*).—Mr. H. G. Sutton reports the death-rate of this district for 1880 as 15·3 per 1000 estimated population, and the birth-rate as 34·5. The district suffered in common with the urban district from scarlet fever and measles. The infectious disease hospital referred to in the urban report is for the use of the rural district also.

Scarborough.—Dr. Taylor reports for the quarter ending the 31st of December, 1880, a death-rate in this town of 18·81 per 1000 inhabitants.

THE MORTALITY OF ASHTON-UNDER-LYNE.

The high death-rate which obtains in Ashton-under-Lyne was recently made a subject of question in the House of Commons; and it is proposed by the Local Government Board to direct a medical inquiry concerning the matter. Portions of the annual report of the medical officer of health of the town have been published in the local journals, and on reading them it is quite apparent why the death-rate of Ashton-under-Lyne should be high, but not equally apparent why it should have been held necessary to bring this swollen mortality before the House of Commons, or set in motion the medical investigation machinery of the Local Government Board. It is evident, indeed, that the local sanitary authority of the town is kept fully and ably informed of those sanitary defects in it which must prove conducive to a high rate of mortality; and whatever be the cause of the sanitary evils of the place, it is not a lack of knowledge of their existence. Ashton-under-Lyne has many of the structural defects of old Lancashire towns, still retains the filthy and immeasurably unwholesome midden-privy system, has imperfect drainage and a not impeccable water-supply, and contains localities in which both the houses and the individuals living within them are overcrowded. The usual concomitants of these conditions are measles, diphtheria, whooping-cough, scarlatina, and fever; and although neither of these diseases has taken on any very exceptional prevalence in the town, each of them, as well as fatal diseases in general, contributes so steadily to the general mortality as to contribute very markedly to a serious total. Bad trade has also lately contributed to the mischievous effects of the unwholesome local conditions. It is the old story, we apprehend, of a sanitary authority too busy in prosperous times to carry out the intimate sanitary administration of its district systematically, and in bad times too depressed and too anxious to spare itself expenses. Publicity, particularly in Parliament, may serve to supply a stimulus to a better action on the part of the sanitary authority; but any way it seems that it is the local administration that is in fault, not the knowledge of what is required to be done.

NOTIFICATION OF INFECTIOUS DISEASES ETC. IN THE METROPOLIS.

The Vestry of Kensington have issued a circular inviting the Metropolitan Vestries and District Boards of Works to appoint delegates to consider at a Conference the advisability of concerting measures to obtain by legislation: "(1) The compulsory disclosure to nuisance authorities of all cases of such dangerous infectious diseases as small-pox, scarlet fever, &c.; (2) an amendment of Section 26 of the Sanitary Act, 1866, so as to provide increased facilities for the removal to hospitals of persons suffering from dangerous infectious diseases, and being without proper lodging or accommodation enabling them to be properly isolated at home; and (3) an enactment for depauperising the relief afforded by way of maintenance, medical treatment, &c., to persons removed for the purpose of isolation to infectious disease hospitals; and for making the support of all such hospitals in the metropolis a charge on the Metropolitan Common Poor Fund." At the request of the vestry, Dr. Dudfield has prepared a special report on these subjects, setting forth their views, and designed to facilitate the discussion of them. Should not the provision of hospital accommodation have preceded the discussion of "notification," &c.? And is there not something inconsistent, at the least, in this movement for "notification of infectious diseases," when the vestries and district boards of the metropolis have so egregiously neglected to make provisions for the isolation of these diseases, without which the "notification" is mainly a sham?

ABERYSTWYTH: A FASHIONABLE WATERING-PLACE.

Aberystwyth is to be congratulated. It is fond of claiming position as "a fashionable watering-place." According to the *Cambrian News*, it may also claim position as one of the filthiest of watering-places. The two positions are by no means irreconcilable; fashion and filth constituting a charming alliteration, which it is evident the Town Council of Aberystwyth think must add to the attractions of the place. Guide-books have much to say about the "pleasantly clean" aspect of the town; but the *Cambrian News* shows it to be a whited sepulchre—in fact, exhibits it as a more or less promiscuous accumulation of houses, filth-heaps, and cesspools, cheek-by-jowl, in which the filth-heaps predominate. Our contemporary is severe upon the local sanitary authority, the Town Council; but, after all, the Town Council may have more in view than it has been credited with locally. If we are preparing here in the metropolis an exhibition of sanitary appliances for the International Sanitary Congress of this year, may not the Aberystwyth Corporation be contemplating for the same Congress an exhibition of insanitary conditions to relieve which the appliances have been devised? Anyway visitors will have the chance of studying them there under the most charming circumstances of surrounding scenery. Medical men, however, will act wisely in erasing the name of Aberystwyth from the list of "health-resorts" for some little time to come.

The Metropolitan Asylums Board, in their formal answer to the deputation regarding Fulham hospital which recently had an interview with them, deny that the statements submitted to them show that the hospital had been a source of dissemination of the disease in the houses in the vicinity. "The percentage of disease admitted (from the whole borough)," the Board says, "to the hospitals of the managers in the epidemics of 1870–72, six years before the building of the hospital, was in excess of the epidemic during which the hospital was in actual operation." As if the "whole borough" were in question! We hesitate to characterise in terms such as it deserves this contemptible prevarication on the part of a public body.

A curious event has happened at the Colchester Workhouse. An old man there, very ill, had a period of somewhat prolonged unconsciousness, during which the attendants believing him to be dead, made the necessary arrangement for "laying out" the body, and notice of the death was sent to his friends. The man, however, revived during the preparations for laying him out, and did not die until the next day. Instructions have been given by the guardians that in future bodies shall not be laid out until death has been certified by the medical officer.

Bristol, following in the wake of other big towns, is beginning to give attention to the sanitary requirements of the class of houses which do not usually occupy the attention of the local sanitary officials, the responsibility for their sanitary condition being held (and properly so) with the owners. Mr. Henry Masters, architect, has been lecturing in the city on the subject, and he expressed the opinion that in Bristol, as in London, there were but a small proportion of houses fit to live in, from a sanitary point of view.

At a recent meeting of the Metropolitan Board of Works a request was preferred by the Fulham District Board for permission to erect a temporary hospital for small-pox at Wormwood Scrubs. The request was refused by twenty-two votes to one. Wormwood Scrubs has been set apart by Act of Parliament as a place of public recreation for ever, and it seems doubtful whether the Metropolitan Board have the power, even if they were willing, to grant the request.

Instructions have been given by the Registrar-General to the registrars throughout England and Wales which will greatly facilitate the discrimination of the births and deaths in the several urban and rural sanitary districts within the registration districts.

A cow-keeper has been fined £5 with costs by the Reigate County Bench for having suffered a man who had, at the time, cases of diphtheria in his family to milk his cows.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality was somewhat higher last week, but was still considerably below its average for the season. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5275 births and 3355 deaths were registered last week. The births exceeded by 89 and the deaths by 98 the average weekly numbers during 1880. The deaths showed an increase of 160 upon the low number returned in the previous week, and were equal to an annual rate of 23·0 per 1000, whereas in the five preceding weeks the rate had steadily declined from 31·0 to 21·9. The lowest death-rates in the twenty towns last week were 17·2 in Brighton, 18·6 in Leicester, 19·5 in Bristol, and 21·1 in Birmingham. The rates in the other towns ranged upwards to 25·2 in Manchester, 25·3 in Salford, 25·8 in Wolverhampton, and 26·5 in Liverpool. During the past nine weeks of the current quarter the death-rate in the twenty towns averaged 24·8 per 1000, against 25·8, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had steadily declined from 390 to 290 in the six preceding weeks, were 296 last week; these included 82 from whooping-cough, 57 from scarlet fever, 53 from small-pox, and only 26 from fever, principally enteric. The annual death-rate from these principal zymotic diseases averaged only 2·0 per 1000 in the twenty towns, and ranged from 0·3 in Hull and 1·0 in Brighton and Newcastle-upon-Tyne, to 3·0 in Norwich and 4·3 in Portsmouth. Whooping-cough showed excessive fatality in Leeds. The 16 deaths referred to diphtheria in the twenty towns included 9 in London, 3 in Portsmouth, and 2 in Salford. The death-rate from fever was unusually low, but showed a proportional excess both in Norwich and Portsmouth. Small-pox caused 54 more deaths in London and its suburban districts, and one in Birmingham, but none in any of the eighteen other provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased in the eighteen preceding weeks from 77 to 752, further rose to 779 on Saturday last, a higher number than has been under treatment in these hospitals since the spring of 1878. The number of new cases admitted to these hospitals, which had been 176, 183, and 187 in the three previous weeks, further rose to 195 last week. The Highgate Small-pox Hospital contained 56 patients on Saturday last, against 46, 53 and 43 at the end of the three preceding weeks, 24 new cases being admitted during the week.

The deaths referred to diseases of the respiratory organs in London, which had been 364 and 367 in the two preceding weeks, further rose to 419 last week, which were, however, 44 below the corrected average number in the corresponding week of the last ten years; 283 resulted from bronchitis, and 75 from pneumonia. The annual death-rate from lung diseases (excluding phthisis) was equal to 5·9 per 1000 in London; the rate from the same diseases was 9·1 in Liverpool.

The causes of 93, or 2·8 per cent., of the deaths in the twenty towns last week were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths was equal to 1·8 per cent. in London, while it averaged 3·6 per cent. in the nineteen provincial towns. No uncertified deaths were registered last week in Portsmouth, Bristol, or Newcastle-upon-Tyne, whereas their proportion was largest in Oldham, Bradford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate averaged 22·9 per 1000 last week, against rates declining steadily from 34·7 to 22·5 in the five preceding weeks; this rate was almost identical with the average rate (23·0) in the twenty large English towns. The rates in the eight Scotch towns ranged from 17·8 and 18·8 in Greenock and Aberdeen, to 25·3 and 29·7 in Perth and Dundee. The deaths referred to the principal zymotic diseases in the eight towns, which had steadily declined from 125 to 70 in the five previous weeks, were 83 last week, and included 28 from whooping-cough, 18 from diphtheria, 15 from scarlet fever, 11 from diarrhœa, 6 from "fever," and 5 from measles. The annual death-rate from these zymotic diseases were equal to 3·3 per 1000, and was 1·3 above the average rate from the same diseases in the twenty English towns; this rate in the eight Scotch towns ranged last week from 1·9 both in Greenock and Perth, to 4·5 and 5·2 in Edinburgh and Leith. The fatal cases of whooping-cough in the eight towns, which had steadily declined from 34 to 17 in the five previous weeks, rose again to 28 last week, and included 11 in Glasgow, 10 in Edinburgh, and 5 in Dundee; the main increase of whooping-cough fatality occurred in Edinburgh. The 18 deaths from diphtheria were also more numerous than those in recent weeks; 7 were returned in Glasgow, 4 in Edinburgh, 2 in Aberdeen, and 2 in Paisley. The fatal cases of scarlet fever also showed a considerable increase, and included 5 in Edinburgh, 4 in Glasgow, 3 in Leith, and 2 in Dundee. The 11 deaths from diarrhœa included 6 in Glasgow and 3 in Aberdeen. The deaths referred to fever, which had been 8, 10, and 14 in the three previous weeks, declined to 6 last week, and included 2 in Glasgow and 2 in Leith; the annual death-rate from fever, however, was again considerably higher than the average rate in the twenty English towns. The deaths referred to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy), which had declined from 348 to 150 in the five preceding weeks, were 179 last week, and were equal to an annual rate of 7·1 per 1000; the death-rate from the same diseases in London did not exceed 5·1 per 1000. The largest excess in the fatality of lung diseases in the Scotch towns occurred last week in Glasgow and Dundee.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, although continuing to decrease, still shows a marked excess. The annual death-rate in the city, which had steadily declined from 47·4 to 38·1 in the five preceding weeks, further fell to 36·0 last week. During the past nine weeks of the current quarter the death-rate in the city has averaged no less than 40·1 per 1000, against 21·7 in London and 22·9 in Edinburgh. The 230 deaths in Dublin last week showed a further decline of 15 from recent weekly numbers, and included 21, or rather more than 9 per cent., which were referred to the principal zymotic diseases, against 31 and 24 in the two previous weeks. These 21 zymotic diseases included 8 from fever (including typhus, enteric or typhoid, and simple continued), 6 from scarlet fever, 5 from whooping-cough, 1 from measles, 1 from diarrhœa, and not one either from small-pox or diphtheria. The annual death-rate from these zymotic diseases was equal to 3·3 per 1000 in Dublin last week; it was only 2·3 in London and was 4·5 in Edinburgh. The deaths referred to fever, which had been 17 and 10 in the two preceding weeks, were 8 last week; these, however, were equal to an annual death-rate seven times as high as the average rate from the same causes last week in the twenty large English towns. The fatal cases of scarlet fever in Dublin, which had been 3 and 4 in the two previous weeks, further rose to 6 last week; those of whooping-cough also showed a slight increase. The deaths of elderly persons showed a further decline from the high numbers returned in recent weeks; whereas those of infants were more numerous than in either of the two previous weeks.

INFANT MORTALITY IN TOWNS.

The Portsmouth Literary and Scientific Society recently devoted an evening to a paper on Infant Mortality, which was read by Dr. Harris. The paper was well calculated to direct public attention to a subject which is generally regarded with far too much apathy. It is to be regretted, however, that the paper was not read in Leicester, Liverpool, or Leeds, in which infant mortality is habitually excessive, instead of in Portsmouth, the comparatively low rate of infant mortality in which town has long been an interesting problem to the students of mortality statistics. Dr. Harris reminded his hearers that in the healthy districts of England the rate of infant mortality did not exceed 103 per 1000, and that if the rate in England and Wales did not exceed this rate there would be an annual saving of about 44,000 infant lives. Such facts as these cannot be too often or too strongly insisted upon, although it would scarcely be reasonable to expect at present that the infantile death-rate in large towns should be comparable with that prevailing in the most healthy of our rural districts. We could have wished that Dr. Harris had illustrated his paper with more recent figures, and we certainly think that scant justice was done to Portsmouth for the favourable comparison which that town affords with most other large towns in the matter of infant mortality. In twenty of the largest English towns the rate of infant mortality during the ten years 1870–9, measured by the proportion of deaths under one year to births registered, averaged 171 per 1000. The lowest rate among these twenty towns was 141 in Portsmouth, the nearest approach to this rate being 158 both in London and Brighton; the rates ranged upwards in the other towns to 187 in Bradford, 188 in Norwich and Manchester, 192 in Leeds, 216 in Liverpool, and 216 in Leicester. It is impossible to doubt that in Portsmouth there is much preventable infant mortality which a well-organised ladies' sanitary organisation, such as was suggested by Dr. Harris, might do much to reduce the rate below the 141 per 1000 which prevailed during the ten years 1870–9. With still greater force, however, should this paper appeal to such towns as Liverpool and Leicester, in which, during the same ten years, the rate of infant mortality exceeded by 75 per 1000 that which was recorded in Portsmouth. During 1880 infant mortality in the twenty towns, although considerably affected by exceptional diarrhœa fatality, averaged 169 per 1000, and was slightly below the average rate in the preceding ten years; it ranged from 146 and 148 in Bristol and Portsmouth, to 202 in Nottingham, 214 in Norwich, and 219 in Leicester. As a means of throwing light upon the real causes of excessive infant mortality, we would suggest to Dr. Harris a careful analysis of the causes of death among infants in Portsmouth and Bristol, compared with those in Norwich and Leicester. We hope that the interest which Dr. Harris's paper deservedly attracted in Portsmouth may be accepted as a sign of increasing public interest in the subject of infant mortality, without which any important reduction cannot be looked for.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

NOTIFICATION OF INFECTIOUS DISEASES IN IRELAND.

The introduction to the House of a Bill to provide for the better notification of infectious diseases in Ireland, improbable as it is to become law, may be accepted as satisfactory evidence that this important subject is beginning to force itself upon public attention. This Bill provides that upon the application of any sanitary authority the Local Government Board of Ireland may issue an order declaring this Act to be in force within the district, or any part of the district, of any sanitary authority; the Local Government Board having power, at their discretion, by a subsequent order to revoke such order. The effect of an order declaring this Act to be in operation would be to oblige any medical practitioner, under penalty of five pounds, to report to the local sanitary authority every case of certain infectious disease he may be called upon to attend. The specified infectious diseases are small-pox, cholera, scarlet fever, typhus, typhoid, puerperal or relapsing fever, diphtheria, measles, or erysipelas, and the Local Government Board has power to add to the list, from time to time, the name of any other acute infectious disease on the application of a sanitary authority. In cases of infectious disease not attended by any medical practitioner the obligation to report to the sanitary authority is imposed upon the occupier of the house, or person having charge of the patient. Within a declared district, within the meaning of this Act, it is enacted that the sanitary authority shall supply gratuitously to every registered practitioner residing within the district forms for certificates, stamped for transmission through the post. The element of failure in this, as in most other proposals for securing the notification of infectious diseases, is the proposed rate of pay to reporting medical practitioners. It is provided that sanitary authorities shall pay a fee of *one shilling* (!) to every medical practitioner for each certificate duly given; but that not more than one fee shall become payable, under this Act, within an interval of thirty days to the same medical practitioner, given by him in respect of the same disease, occurring in the same building. There can be little doubt that the prompt notification of infectious diseases lies at the very root of successful sanitation; but desirable as this is, we shall be surprised if any general Act of this nature become law which throws this unpleasant responsibility upon the medical practitioner, and proposes to award him the paltry sum of one shilling for each such certificate furnished to the sanitary authority.

AN APOLOGY FOR "DRAUGHTS."

The *Builder* has a sort of good word to say for draughts. Of course, ventilation accompanied with draughts is too terrific a conception to enter into a properly-balanced mind (leaving the influence of draughts on the body out of the account). But as existing dwellings are and the average Britisher is constituted, the person who conceives that it is possible in the present and near future to establish typical ventilation in the majority of English houses must have that enviable state of intellect which accepts the history of Jack the Giant-killer as not the least carefully verified and important portion of the history of Great Britain. If the Britisher prefers draughts, we "must allow," as the *Builder* judiciously phrases it, the preference; and he should be advised to adopt Mrs. Lirriper's opinions as to smoke—that is to take it plain, and not as presented in all sorts of mysterious and wonderful modes by the ingenuity of patentees.

ARTIFICIAL VACCINE LYMPH.

Mr. J. Lawrence-Hamilton proposes to introduce an abundant supply of pure artificial lymph, produced outside the body of living man or living animal, by isolating and then breeding the vaccine organisms in suitable germ nutritive solutions which have been previously deprived of all septic and other noxious germs. The publication of the special precautions and physical conditions which Mr. J. Lawrence-Hamilton considers necessary to secure safety and success in breeding, and then in employing the artificial vaccine lymph, as well as the results of therewith inoculating men, cattle, and other animals, will be postponed till a subsequent date.

RUSSIAN MEDICO-SANITARY NEWS.

Under the will of the late Empress Marie Alexandrovna, 150,000 roubles have been handed over to the Russian Red-cross Society, the balance of a sum collected after the Crimean war for the education of the orphans of soldiers killed or who died of their wounds during the war.—The subject of diphtheria is still causing much anxiety in Russia. A congress of the zemstvos of Kharkov, Poltava, Catherinoslaw, Tcheringow, Koursk, and Voronege, has been held in the city of Kharkov, to consider a general plan for dealing with the epidemic. This is stated to be the first example of a conference of delegates of various local governments.

THE PLAGUE.

The most recent news received on the reported outbreak of plague in Mesopotamia leave little doubt that the report is correct, and that the scene of the outbreak is on the Lower Euphrates—the scene, in fact, of the outbreak of the disease in 1873-74. In view of this reappearance of the disease the map of this district, and the particulars relating to it, given in the Parliamentary Paper on Plague, published during the session of 1879, have great interest.

It is reported that the landlord of a house at Dorking sued his tenant at the County Court on Wednesday for the cost of disinfecting his house, an outbreak of scarlatina having taken place, which it was shown had been brought into the neighbourhood by the defendant. Judgment was given for the plaintiff.

The subject of Sanitary Protection Associations seems to be exciting considerable attention in Yorkshire. Among other advocates, Mr. Dolan of Halifax sets forth their advantages *à propos* of the recent serious outbreak of scarlet fever in that town.

Our contemporary, *The Globe*, has the following:—"As was to be expected, small-pox has broken out in Leicester. Mr. P. A. Taylor's constituents will now have an opportunity of estimating the worth of the anti-vaccination movement, with which their representative has identified himself."

Professor Fleeming Jenkin has been lecturing at Bradford, in Yorkshire, on the desirability of forming a Sanitary Protection Association there, and his suggestions will be acted upon.

Small-pox is stated to be raging in the Sandwich Islands. A *cordon* has been placed around several houses in Honolulu, and free communication between the islands has been suspended.

At the annual meeting of the Bolton Infirmary and Dispensary, after the reading of the report, which was in every respect satisfactory, the chairman said he had received a letter from Mr. Turner of Camden-road, London, enclosing a cheque for £50 in acknowledgment of the care and attention bestowed upon his son whilst in the institution. The lad, it appears, had sustained a fracture of the base of the skull and other severe injuries from having fallen between the platform and railway carriages on the Lancashire and Yorkshire line, but had, under the skilful attendance of the medical officers of the infirmary, quite recovered.

The concert given this year by the staff of the South-Western Railway at Guildford, in aid of the funds of the Royal Surrey County Hospital, realised over £20.

THE SERVICES.

THE TRANSVAAL WAR.

Further reinforcements in men and *matériel* for the medical service in South Africa have been ordered by the War Office authorities during the past week. Four surgery and four pharmacy waggons, with a number of ambulances, have been despatched from Woolwich Arsenal and stored on board the transport *Thames*, which also takes out a large quantity of medicines, medical and surgical stores, medical comforts, &c. The complete equipment for two movable field hospitals, which give accommodation for 400 beds, will also be sent out without delay. A detachment of thirty-seven rank and file of the Army Hospital Corps, under the command of Lieutenant of Orderlies, J. Mullins, sailed in the mail steamer *Roman* from Southampton on Thursday last for Durban, and a further detachment of sixty-three, under Lieutenant J. Thompson, is held in readiness for immediate embarkation. Deputy Surgeon-General J. Sinclair and Surgeon-Major St. John Stanley were also provided with passages in the *Roman*. Surgeon-Major F. B. Scott, M.D., sailed in the *Balmoral Castle* on the 5th inst. for Natal.

VOLUNTEER AMBULANCE DEPARTMENT.

A parade of the Volunteers who have completed a course of instruction in ambulance and stretcher drill took place at the Guildhall, by the kind permission of the Right Hon. the Lord Mayor, on Wednesday, the 2nd instant, when the certificates of proficiency in this very useful work were presented to over one hundred members of the Volunteer Ambulance Department by Mr. Sheriff Fowler, in the unavoidable absence of Sir Thomas Truscott. Prior to the Sheriff's arrival an inspection of the men was made by Surgeon-General Shelton, President of the Society, who was accompanied by a staff of Army Medical Officers. The classes of instruction were three in number, and were in charge of Surgeon Ellis, 10th Kent Rifles, Surgeon Hicks, 1st Bedford, and Surgeon Andrew Clarke, Middlesex Volunteers. The men were put through the usual evolutions of stretcher drill, including the application of bandages, splints, and tourniquets—proceedings which were witnessed by the Sheriff and a large number of spectators with much interest. After handing the certificates to the class, Mr. Fowler addressed the parade at some length, complimenting the men on their steadiness and proficiency, and expressing his pleasure at the interesting manœuvres he had witnessed. Surgeon-General Shelton announced that the Secretary of State for War had authorised a badge similar to that worn by the Army Hospital Corps, but with silver instead of worsted lace, to be worn on the right arm by two men in each company of volunteers, who are to be enrolled as the recognised stretcher-bearers of the regiment. Dr. Shelton computed that in time they will number no less than 4000, a corps or department therefore of much importance. The Surgeon-General also announced that sanction had been received for the formation of a Volunteer-Bearer Company, to take part in the anticipated review at Windsor before H.M. the Queen.

Brigade-Surgeon C. G. Irwin, M.D., and Surgeon J. Wilson, Army Medical Department, are ordered to Cape Coast Castle for service on the West Coast of Africa.

Brigade-Surgeon Adam G. Young has arrived in England on six months' leave of absence.

Surgeon-Major Atkins has been appointed to the medical charge of the Convalescent Depôt at Dalhousie, and Surgeon-Major Ambrose to the Convalescent Depôt at Kasauli.

Surgeon-Major Alfred Sanderson, M.D., Madras Medical Service, has, we hear, been offered by telegram a Deputy Surgeon General's appointment in that Presidency—vice Oswald, proceeding home on furlough.

ADMIRALTY.—The following appointments have been made: Surgeon John K. Conway, to the *Liffey*; Surgeon Henry D. Collins, to the *Duke of Wellington*, additional, for temporary service at Haslar Hospital.

DR. THOMAS (says the "Colonies and India") has been dismissed summarily from the Melbourne Hospital for declining to give a death certificate.

THE HAMPSTEAD SMALL-POX HOSPITAL CASE.

THE MANAGERS OF THE METROPOLITAN ASYLUM DISTRICT *v.* HILL AND OTHERS.

THE appeal to the House of Lords from a decision of the Court of Appeal, reversing a judgment of the Queen's Bench Division, which made a rule absolute for a new trial in this case, and dissolved an injunction restraining the defendants, the present appellants, from using the Hampstead Small-pox Hospital as a hospital for patients suffering from small-pox or other infectious diseases, was decided on March 7th. The noble and learned lords present were the Lord Chancellor, Lord Blackburn, and Lord Watson. The action was brought by the plaintiffs, the present respondents, to recover damages for a nuisance arising from the use by the defendants of their hospital at Hampstead for small-pox and other infectious and contagious diseases, and for causing the assemblage in the neighbourhood of the plaintiffs' property of large numbers of persons suffering from such diseases and from offensive smells and noises arising from the use of the hospital, and also asking for an injunction to restrain the defendants from so using the hospital. The case came on for trial before Mr. Baron Pollock, when the jury found that the hospital was so carried on as to be a nuisance to the neighbourhood. The Queen's Bench Division made absolute a rule for a new trial and dissolved the injunction, which decision was set aside by the Court of Appeal. The case was argued on appeal before their Lordships some time ago, when judgment was reversed. Their Lordships delivered judgment in favour of the respondents.

The LORD CHANCELLOR.—It must be assumed, for the present purpose, that the small-pox hospital which the appellants have established at Hampstead is, in its actual position, and independently of the particular way in which it is conducted, necessarily a nuisance to the neighbours; and the injunction which has been granted by the order appealed against is against "using the plot of land mentioned in the statement of claim and buildings thereon as a hospital for small-pox or any other infectious or contagious disorder in such manner as to create a nuisance to the plaintiffs or either of them." The appellants are, therefore, obliged, in order to succeed in this appeal, to prove that they have statutory authority to create a nuisance for the purpose of and as incidental to the maintenance of a small-pox hospital in this place. The appellants say that such authority has been given to them by the 5th, 7th, and 15th sections of the Metropolitan Poor Act, 1867, and by orders of the Poor Law Board made pursuant thereto. As far as the orders of the Poor Law Board are concerned, they did, undoubtedly, direct the appellants to purchase the land in question at a specified price, and to build upon it an asylum for the reception of poor persons infected with or suffering from fever or small-pox; and I assume that the building as erected and fitted up on that land is in strict accordance with plans which the Poor Law Board has prescribed or approved. The statute, when examined, is found to confer, in general terms, powers extending over a rather wide range of subjects. So far as relates to a hospital or asylum of this particular kind, there is nothing in it mandatory or imperative. Everything which it necessarily requires may be done, though no such hospital should ever or anywhere be established. The 5th section says that "asylums, to be supported and managed according to this Act, may be provided under this Act for reception or relief of the sick, insane, or infirm, or other class or classes of the poor chargeable in unions or parishes in the metropolis." The 6th section authorises the formation of districts; and the 7th requires that in each district so formed "there shall be an asylum or asylums, as the Poor Law Board from time to time by order direct"; leaving the class of poor persons, for whom any such asylum may be provided, entirely open. The 15th section enables the Poor Law Board from time to time, by order, to direct the managers "to purchase or hire, or to build and (in either case) to fit up a building or buildings for the asylum of such nature and size, and according to such plan, and in such manner as the Poor Law Board think fit"; and the managers are required to carry such directions into execution. Subsequent clauses put the arrangements and conduct of any such asylum under the superintendence of the Poor Law Board. No compulsory power is given to acquire land or any interest in land for any asylum purposes. The Lands Clauses Acts are, indeed, incorporated by Section 52; but Section 53 expressly provides that so much of those Acts as relates to the purchase of land otherwise than by agreement shall not be put in force except for certain purposes, not including these asylums. It appears incidentally from Section 69 (which provides for the repayment of certain expenses therein specified out of the common poor fund) that asylums might be "specially provided under this Act for patients suffering from fever or small-pox"; but, except in that way, and from the fact that the general category of "sick" necessarily includes patients suffering from any kind of disease, there is no provision in the Act as to contagious or infectious disorders. If express words or necessary implication and intendment must be shown in order to authorise the Poor Law Board, or any managers of an asylum, to create a nuisance in the exercise of the discretionary powers given to them, I can find none in this statute.

The result is (1) that this Act does not necessarily require anything to be done under it which might not be done without causing a nuisance.

(2) That, as to those things which may or may not be done under it, there is no evidence on the face of the Act that the Legislature supposed it to be impossible for any of them to be done (if they were done at all) somewhere and under some circumstances without creating a nuisance; and

(3) That the Legislature has manifested no intention that any of these optional powers should be exercised at the expense of or so as to interfere with any man's private rights.

The only sense in which the Legislature can be properly said to have authorised these things to be done is that it has enabled the Poor Law Board to order and the managers to do them if, and when, and where, they can obtain, by free bargain and contract, the means of doing so.

If the Legislature had authorised some compulsory interference with private rights of property, within local limits which it might have thought fit to define, for the purpose of establishing this asylum to be used for the reception of patients suffering from small-pox or other infectious disorders, and had provided for compensation to those who might be thereby injuriously affected (in such case and under such conditions as it might have prescribed), the present case might have been like "Rex *v.* Pease" and "Brand *v.* Hammersmith Railway Company." No person outside the statutory line of compensation, even if the use of the asylum in the manner authorised by the statute had been productive of serious damage to him, could then have obtained any relief or remedy upon the footing that what the statute authorised was a legal nuisance to himself or an actionable wrong. But the case is different when (as here) no interference at all with any private rights is authorised, and no place, or limit of space, is defined, within which the establishment of such an asylum is made lawful. Neither the Poor Law Board nor the managers could for this purpose have taken a single foot of ground or have interfered with any the most insignificant easement against the will of the plaintiffs, or of any other person to whom such land or easement might belong. No line is here drawn by the Legislature between interests which are and interests which are not proper subjects for compensation. Under these circumstances, I am clearly of opinion that the Poor Law Board and the managers had no statutory authority to do anything which might be a nuisance to the plaintiffs without their consent. I therefore move your Lordships to affirm the judgment of the Court below, and dismiss this appeal.

Lord BLACKBURN delivered a lengthened judgment to the same effect.

Lord WATSON also concurred.

The judgment of the Queen's Bench Division was reversed accordingly, and the appeal was dismissed with costs.

SICK CHILDREN'S HOSPITAL, BRIGHTON.—At the twelfth annual meeting of the supporters of this hospital the committee reported that at the recent bazaar held on behalf of the funds of the institution the sum of £2230 was raised towards the completion of the new building, which will be opened by a member of the Royal Family in April next, and the total cost of which is estimated at £11,000.

THE FULHAM SMALL-POX HOSPITAL.

MR. FIRTH, M.P., presided over a meeting held on Monday evening, at the Vestry-hall, King's-road, Chelsea, to protest against the extension of the Small-pox and Fever Hospital at Fulham, and to take such steps as might be deemed advisable. The chairman remarked that the question upon which they had met to take counsel had been considered by several meetings in the borough, and was one of very great importance. Hospitals of a special character had been established at Hampstead, Homerton, and Stockwell, and subsequently land for a similar purpose had been purchased at West Brompton, though at the time the land was purchased nobody knew what was the purpose for which it was acquired. The people of Chelsea objected to have a disease like small-pox distributed throughout their district. In the Hampstead case it had been contended that it was no disadvantage to have such an establishment. But a great many people accepted the "germ" theory. The district of Fulham had been considered the most salubrious in the metropolis, but here they found that houses in a direct line with the hospital, between which no tree or house intervened, were places where the disease was apt to break out. If the wind blew in a particular direction the germs might be conveyed to persons looking out of a window. The appeal to the House of Lords in the case of the Hampstead Hospital had been decided that day, and that might render their position somewhat different. He referred to a letter from Dr. Francis Godrich, medical officer for Brompton, in which he stated that during the last three years, ending December 31st, 1880, 213 parochial cases were sent into the hospital, of which number 124 came from within about a quarter of a mile's distance of it, which includes an area not at all densely populated, quite two-thirds being open ground, 55 from an area situated between a quarter and a half mile of the hospital, and the remaining 34 were scattered over the rest of the district, extending about two miles from the hospital. A resolution was passed unanimously that the use of the Small-pox and Fever Hospital at Fulham should be confined to the four parishes constituted by the borough of Chelsea. A further resolution was submitted, declaring that, inasmuch as the Metropolitan Asylums Board had declined to limit the Small-pox and Fever Hospital at Fulham to the inhabitants of the borough of Chelsea, and as the Local Government Board had declined to receive a deputation from the inhabitants of that borough on the subject the meeting would support the committee in the prosecution of such legal proceedings as might be necessary to vindicate the rights of the district, and that a subscription and guarantee fund be formed.

On Tuesday evening a largely-attended meeting of the committee formed to take action with respect to the spread of small-pox through the cases brought to the Fulham Small-pox Hospital was held at Messrs. Tattersall's, Knightsbridge—Mr. Firth, M.P., in the chair. Amongst others present was Mr. Pearson Hill, son of the late Sir Rowland Hill, who was the plaintiff in the protracted litigation with the Metropolitan Asylums Board with respect to the Hampstead Hospital. Mr. Hill attended at the request of the committee to explain what had been done in the Hampstead case. In the discussion which took place it was understood that immediate steps would be taken to apply for an injunction to prevent any further small-pox patients being received into the Fulham Hospital; and that there should be no attempt at interference with the patients at present under treatment. Several members of the committee put down their names for £25 towards a guarantee fund, and other gentlemen present also subscribed to it. The following resolutions were passed:—1. "That this committee do now resolve to take immediate action as they may be advised to prevent further small-pox patients being sent to Fulham Hospital, due regard being had to the safety of patients now under treatment there." 2. "That an executive committee be formed to arrange as to matters of finance, and in that respect carry out the above resolution." 3. "That a sub-committee be appointed for each district to make a house-to-house canvas for subscriptions towards the preliminary expenses and the guarantee fund." The other business consisted of the appointment of various committees, which were to meet every day during the next fortnight.

MEDICAL NOTES IN PARLIAMENT.

Alkali Works.

THE House of Lords on Tuesday having gone into Committee on the Alkali Works Regulation Bill, several of the clauses were agreed to after unopposed amendments had been inserted on the motion of Lord Huntly, who had charge of the measure. On Clause 7, Lord Midleton moved an amendment having for its object to bring coke ovens within the operation of the Bill. The amendment was opposed by Lord Huntly, and rejected by a majority of 18. Ultimately the Bill was reported to the House with only the amendments introduced, or agreed to without discussion, by Lord Huntly, on behalf of the Government.

In the House of Commons on Thursday, March 3rd, further petitions for inquiry into the East India Army Medical Department were presented from Messrs. T. Ringer and G. Bainbridge.

On Friday a petition was presented from the parish of St. Martin-in-the-Fields praying for an alteration of the law with regard to infectious diseases. Mr. Healy moved the second reading of the Coroners (Ireland) Bill, which was at first opposed by the Attorney-General for Ireland, but subsequently by arrangement the second reading was agreed to, and the Bill was referred to a Select Committee.

The Drug Trade.

Mr. Gabbett asked the Secretary of State for War whether medicines are provided for the army in England by inviting tenders from the drug trade, and if not thus, in what manner; whether the practice that exists in England is applied in Ireland, and whether the Irish drug trade receive invitations to tender for supplies. Mr. Childers replied that in England quarterly requisitions were received from about a hundred stations, and drugs were supplied direct, either by the Apothecaries' Company or by Savory and Moore, according to the prices at which they tendered. In Ireland the drugs were supplied by the Apothecaries' Company in Dublin, and the prices were always checked by returns from the department.

Fulham Small-pox Hospital.

Mr. Firth asked the President of the Local Government Board whether the decision in the case of Hill *v.* The Metropolitan Asylums Board would modify the action of the Local Government Board in reference to Fulham Hospital. Mr. Dodson said, in view of the small-pox epidemic, this was a serious question, not to be hastily answered. He knew nothing of the nature of the judgment except by general report, and desired to have an opportunity of considering it before he came to a conclusion as to what steps ought to be taken.

Wanted, a Specific for Small-pox.

The following notice was given for this Thursday:—Mr. Daniel Grant, to ask the President of the Local Government Board whether, considering how constantly epidemics of small-pox recur, the large number of deaths which are annually returned, the wide differences of opinion that exist among fully qualified medical men as to the limits of the protective power of vaccination, and with respect to the genesis, distribution, and limitations of contagion, he will take into his consideration the advisability of offering a series of substantial premiums, open to all the world, for obtaining concise, accurate, and fully tested information as to the origin, growth, and development of the disease; also such other practical knowledge as will tend to minimise its power of infection and indicate the means for its extinction; and whether it may with propriety be assumed that, if any person can discover an absolute specific for the disease itself, a full pecuniary recognition would be awarded.

On Thursday, in reply to Mr. Grant's question, Mr. Dodson declined to enter into the various points raised in the preamble, but asked the hon. member to accept "as a practical and conclusive answer" an assurance that he (Mr. Dodson) had no funds whatever applicable to such a purpose.

On Monday petitions for inquiry into the East India Army Medical Department were presented from Messrs. J. Murray, F. H. Blinkinsop, E. Selens, J. B. Eaton, A. E. Stephens, W. Watson, G. Henderson, A. J. Dale, J. Cruickshank, A. Adey, and R. Murray.

Animal Vaccine.

The following notice was given for Thursday:—Dr. Cameron, to ask the President of the Local Government Board whether any steps have been taken to give effect to his promise, made on the 11th of June last, that the Vaccination Department should supply calf lymph as "stock" for vaccination to such medical practitioners as preferred it to ordinary humanised lymph; and whether, in view of the alarming spread of small-pox in London, the department would consider the propriety of taking measures to secure a sufficient supply of vaccine lymph for the purpose of re-vaccination.

Trichinosis.

On Tuesday, in reply to Dr. Farquharson, Mr. Dodson said, no case of trichinosis had been reported in this country, and he stated that there was no cause for alarm. But looking at reports from other countries of the existence of trichinosis, and at the report of Dr. Ballard, with regard to the recent outbreak of diarrhœal disease at Welbeck, he had thought it advisable to issue a circular to local authorities, pointing out certain precautions, and recommending vigilance on the part of medical officers of health in regard to the proper inspection of pork and hams. Mr. Talbot gave notice of a question for Thursday, with regard to the provision of fever and small-pox hospitals for the metropolis.

On Wednesday petitions for an alteration in the Scotch law and medical relief were presented from Stirling, Thurso, and Rendall.

The Contagious Diseases Acts in Bombay.

Mr. Hopwood gave notice of his intention on Tuesday next to ask the Secretary of State for India whether he is aware that the Contagious Diseases Act was reapplied to Bombay early in 1880, in spite of strong objection expressed by a large number of influential natives and Europeans, including the Bishop of Bombay; whether the native justices and Municipal Council of Bombay have not declined throughout to vote money towards the expenses of the working of the Act; whether the Government of Bombay have deducted the sum of 15,000 rupees from the grant of 90,000 rupees usually paid by the Government towards the expenses of the Bombay city police, although the grant was long previously agreed upon, after full discussion between the Municipality and the Supreme and Local Governments; and whether the Home Government approve of the forcing of the Acts in question upon a population so sensitive and peculiar as that of India in regard to the treatment of women.

Vaccination in Prisons.

Mr. Yorke asked the Secretary of State for the Home Department whether the medical officers of Her Majesty's prisons are required by the regulations to vaccinate all children born in the prisons before they are allowed to go out; and, if so, whether such regulations are strictly enforced, especially in the case of the female prison at Westminster. Sir W. Harcourt said he had not had time to inquire into the facts, but would do so.

Correspondence.

"Audi alteram partem."

FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

To the Editor of THE LANCET.

SIR,—Referring to Sir Trevor Lawrence's question in the House last night, and to the letters which have recently appeared in your columns, one would really suppose that the Scotch medical corporations were the *only* bodies who exacted payment for the Fellowship, and who granted it without examination.

I do not seek to defend the Edinburgh College of Surgeons, which has, I know, admitted many men to its Fellowship whose right to that honour was, at least, doubtful; but why such a virtuous outcry about "payment" and the absence of any examination? Does not the English College of Surgeons admit a large number of Fellows by election and without examination, and are not all the Fellows of the English and Irish Colleges of Physicians admitted by election and without examination? And do not all these bodies exact fees in return for the honour conferred?

There can be no objection to the Fellowship of any learned body being conferred on worthy subjects by the votes of the existing Fellows, but I fully admit that the candidates should first have proved themselves to be deserving of the honour. I remain, Sir, yours obediently,

March 1st, 1881. F.R.C.S. EDIN.

*** Though the mode of election of Fellows of the R.C.P. London may not be perfectly satisfactory, our correspondent must be aware that the process and the results are very different from those of the Scotch Corporations. A Fellowship cannot be *bought* at the London College as in Edinburgh, but it is conferred as a mark of distinction by the suffrages of the Fellows of the College. The system of election in the King and Queen's College of Ireland is, we fear, too like that of the Scotch Corporations. But neither in the English nor the Irish College of Surgeons is the Fellowship to be had now without examination, except as regards the latter in certain rare and well-defined cases. The only instances in which the Fellowship of the Royal College of Surgeons of England can be obtained without examination are (1) in the case of persons who were Members before Sept. 14th, 1843, on the recommendation of six Fellows; (2) the Council of the College has the power to elect annually two Members of twenty years' standing, but there are only three Fellows who have been elected in this way; (3) by an *ad eundem* admission of Fellows of the Irish College of Surgeons, of which there are *two*. It is satisfactory to know that all these questions are to be investigated by a Royal Commission.—ED. L.

THE POTTED MEAT TRADE.

To the Editor of THE LANCET.

SIR,—If there is one trade that requires supervision it is the potted meat trade. For several years past I have from time to time had very clear cases of poisoning from the use of potted meats as sold in the country. In one instance a lady had some potted salmon for luncheon; in less than an hour she was taken violently ill with sickness, pain in the region of the stomach, and a feeling of faintness. One of her daughters was similarly, though in a less degree, affected; neither of the ladies had the smallest doubt that the potted salmon was the cause of the illness. Another time several boys were affected with sickness and great gastric disturbance; that was also attributed to potted fish, lobster, if I remember rightly. Again, a pot of so-called potted shrimps that had disagreed with two boys was sent to me. I found that it mainly consisted of a pultaceous substance, coloured with venetian red. Under a low-power microscope fragments of small crab shells were found to be abundant. The mass seemed to be composed of pounded crabs, possibly some herring roe, grease of some kind, and venetian red. In another instance a tin of potted food was brought to me. It looked fresh, and from the cover it seemed to be just out of the manufactory. There was a small tear in the cover, and on enlarging the hole another cover was seen underneath entirely defaced by ironmould, so that it is possible for the potted contents of the tin to have been years old and to have been fraudulently made to look new by placing a clean and new label upon it. It will be in the recollection of many how a large quantity of the tinned meat that was supplied by a respectable firm for use in the Crimea was discovered at Devonport, fortunately before shipment, to be in a putrid and utterly unusable condition. I have been led to make these statements and remarks from having had the following extract from the *Huddersfield Examiner* given to me:—

"*A Potted Meat Manufactory: Disgusting Discovery.*

"On Saturday a disgusting discovery was made on the premises of a potted meat manufacturer. Entering the premises Superintendent Buckley and Inspector Latham found in the manufactory a steam machine in operation, and about 1300 lb. of diseased horseflesh, mutton, &c., in various stages, from the 'raw material' to the 'finished' potted meat, sausages, saveloys, savoury ducks, German polonies, &c. There were nearly 200 lb. weight of sausages recently made, and coloured with red ochre to give them a fresh appearance. Two diseased sheep, dressed but uncut, were in the manufactory, besides quarters, breasts, legs, and shoulders of diseased mutton, besides 200 lb. weight of diseased horseflesh, cut into small pieces, cans of recently made potted meat, the meat being mostly horseflesh, horribly diseased and coloured with red ochre, large German polonies of equally unwholesome, if not poisonous, material, and a large number of tins ready to receive as potted meat the strange compounds. The borough and county medical officers immediately condemned the meat, remarking that they had never seen such a disgusting collection. A tin of red ochre was also found in the loathsome manufactory. Magisterial proceedings will necessarily follow."

I understand that the magistrates inflicted three months' imprisonment, remarking that it was the utmost penalty that they could enforce. It is impossible to use too strong terms against such nefarious proceedings, and while the alarm of trichinæ is occupying the public mind the abomination to which the potted meat trade can descend ought not to be lost sight of.—Yours very truly,

WALTER FERGUS, M.D.

Marlborough College, March 7th, 1881.

CYSTICERCUS IN THE BRAIN.

To the Editor of THE LANCET.

SIR,—The occurrence of pork measles in the human brain is so rare that perhaps you will allow me to mention that Dr. Flint of Scarborough has just sent me a specimen of Cysticercus cellulosæ which, apart from its unusual habitat and the clinical interest attaching to it, exhibits some strange peculiarities. In the uninjured state the bladder-worm was fully as large as a cherry, having the width of a shilling piece. When unrolled and gently extended on a slide it reached a length of two inches. On dissecting out the head I was not a little surprised to find that it was furnished with six suckers. This reminds one of Zenker's example of a monstrous Tænia solium recently figured and described by Heller ("Die Schmarotzer," s. 41). It is to be hoped that Dr. Flint will publish his case. The specimen will be shown at the next meeting of the Quekett Club.

I am, Sir, yours truly,

London, March 7th, 1881. T. SPENCER COBBOLD.

EMPYEMA AND ITS TREATMENT BY FREE INCISION, IRRIGATION, AND ASPIRATION.

To the Editor of THE LANCET.

SIR,—Mr. Lowe is a little severe upon me in his criticism of my case.

Firstly, he thinks I claim priority in performing the above operation by free incision, irrigation, and aspiration, with Listerian precautions. I assure him I do not. All that I say in my little paper is, that this case (the one reported) may be the first done according to the directions of Professor Fraentzel, as given in Ziemssen's Cyclopædia; and I may add, by the way, that Fraentzel in this article says he himself derived the plan of proceeding from Traube. This, my "claim," however, is sufficiently disposed of by a report in the last number of THE LANCET, by Dr. Ferguson of Cheltenham, of two cases, one of which, at any rate, was treated in 1879, and I am pleased to acknowledge his priority, as also to find he appreciates the operation as he does. As I only followed implicitly Fraentzel's directions, I will leave him to fight out with Mr. Lowe, if he thinks proper, the science and common sense of the arrangements, just adding that if Mr. Lowe would read his beautiful article on Pleurisy, he would not, I am sure, think him deficient in either the one or the other.

The distilled water was only used for the first forty-eight hours, and was heated to from 100° to 103° F. I am in hopes it washed away all disease germs then existing, and that the subsequent antiseptic washings destroyed any, if introduced by it. As to the other Listerian precautions, all were carried out—instruments, tubes, hands, funnel, syringe, and even clothes, were freely carbolised. The spray was used during all manipulations, and carbolised gauze applied after.

I believe that the temperature of the water rendered harmless, though it might not have destroyed, these mischievous little entities. At any rate, there was no evidence in our case that any harm resulted from their (according to Mr. Lowe) unopposed sojourn in the pleural cavity.

The free incision and emptying of the cavity require a word. If Mr. Lowe had seen the immense masses of pus-sodden fibrine belched out, as it were, from the aperture, some of them requiring even forceps for their complete ejection, I think perhaps he would not have regretted the freeness of the opening, but would rather have wished he had made it a little more free. But let him observe what I now tell him: that two carbolised fingers were introduced now and then into the wound, to stay the flow of the fluid when judged to be too rapid, according to Fraentzel's minute directions. All authorities, I think, agree that when the fluid contained in the pleural cavity is proved to be pus (as it was in our case by a preliminary exploring aspiration) the outlet should be free; but I do not think this has been so precisely laid down by anyone as it has been by Fraentzel.

Now, as to the patient's case before operation. I may state the boy had been ill, a month before I saw him, with dyspnœa, pain, emaciation, and sweatings. The left side was enlarged, smooth, and motionless; the upper and lateral parts were perfectly œdematous; there was complete dulness, and complete absence of respiratory murmur, except at the apex anteriorly, and here and for some short distance below posteriorly. The vocal fremitus was absent, though easily felt on the other side, and measurement round just below the nipple line showed half an inch more on this side than on the other, which, as it was the left side in a right-handed person, made a difference of one inch in the relative size. The case was, in fact, one of empyema proper, not one of circumscribed suppuration.

One advantage of the method I will just mention. The whole proceeding enables one to judge, by smell, sight, and touch, much of what is taking place in the pleural cavity. For instance, in our case masses of soaked fibrine came away at the time of the incision, and for a day or two after. For a week or two our two tubes would only pass in one direction, and then came a gush of greenish pus, all that had been previously washed away having been nearly white. At the same time there was a rise of temperature, and a small spot of dulness, with tubular breathing behind. This enabled me to say to a medical friend, "You may depend upon it there is a piece of the old lymph, which has not come away, which has kept open a sinus between the two pleural surfaces, and has caused a local abscess." In the second or third washing after, this piece of lymph blocked the exit tube and was removed. It had evidently lodged between the two lobes of the lung.

I find I have omitted alluding to one point mentioned by Mr. Lowe—viz., the weakness of the carbolic acid solution. Our great ovarian operators have, it seems, come to use their solutions much more diluted than Lister's; for reasons which certainly apply to the pleural cavity—the avoidance of local irritation and general absorption. I doubt not similar reasoning influenced Fraentzel and Traube, and would certainly influence me, in treating any similar case, to use the same strength as I did with confidence in its antiseptic influence. I am, Sir, yours, &c.,

WM. W. MOXHAY,
Surgeon Royal Berks Hospital.

Reading, March 7th, 1881.

"CASE OF PROBABLE POISONING BY COLCHICUM."

To the Editor of THE LANCET.

SIR,—My attention has been directed to the above case in last week's LANCET, sent to you by my neighbour, Dr. C. Budd of North Tawton. As I am the medical man alluded to who attended the case during the first seven days, I shall feel obliged if you will allow me to correct a mistake and an omission of Dr. Budd's respecting the patient's illness during the time he was under my care.

I saw the patient for the first time on Tuesday, Sept. 7th, and was told by him he had been shooting in Scotland, where he had taken a great amount of walking exercise, and had suffered occasionally from gouty pains in the knee. He informed me—which Dr. Budd's account does not mention—that on the morning he was leaving Scotland for Devonshire he was standing on the railway line talking to a friend, when an empty truck, which was being shunted and unperceived by him, struck him with such violence as to make him think he was being run over, and, as he expressed it, he was terribly frightened as well as shaken. On his arrival at Exeter, late on Saturday night, he drank iced water with a quantity of lemon-juice. Two days after he came home I saw him for the first time, and found him suffering from diarrhœa, vomiting, and hiccough, as described by Dr. Budd. Being fully aware of the patient's gouty diathesis and the irregular mode of living a visit to Scotland for grouse shooting entails, the great nervous shock he experienced on being violently knocked down by the empty truck, besides a long fatiguing journey, and at the end of which drinking a quantity of iced water with lemon-juice, did, in my opinion, account for the symptoms he then suffered from. My treatment may be described as essentially soothing and corrective, and it was so far successful that on the Monday following (the sixth day of my attendance) the diarrhœa, vomiting, and hiccough had completely subsided. (Dr. Budd says he obtained no relief.) He was free from pain, with a clean, moist tongue; pulse natural and secretions healthy, but suffering greatly from weakness, although not more than might be expected. At his own request I allowed some champagne and a few oysters to be taken on the following day.

I considered him so much improved that I suggested passing over one day without seeing him, to which he readily assented. My attendance, however, now ceased, as on the following day he sent for another medical man without informing me of his desire to have a second opinion. In my annoyance I refused to visit him again.

What caused a return of all the previous symptoms and the fatal termination I would not venture to say, but I cannot for a moment agree with Dr. Budd that it was a case of poisoning by colchicum; had it been so the case could not possibly have improved to so great an extent as it had when I left him, and then returned with double violence about forty-eight hours after I last saw him.

The final issue, as described by Dr. Budd, points, I think, to a rapid cerebro-spinal effusion, caused possibly by a gouty poison, instead of colchicum.

I am, Sir, your obedient servant,
JOHN GOULD, M.R.C.S. & L.A.C.

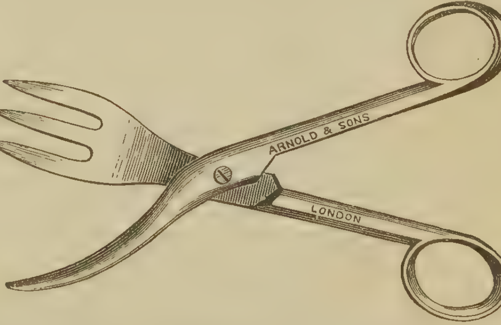
Hatherleigh, March 7th, 1881.

"THE DESIDERATUM."

To the Editor of THE LANCET.

SIR,—The instrument of which the enclosed is an illustration (and which I have named "The Desideratum" for the purpose of registration) was invented by me to obviate as far as possible the awkwardness and inconvenience attendant on the eating of their meals by persons deprived of the use of either arm.

You will perceive that it is on the principle of the shears, being formed of a fork and cutting-blade, which enables the person using it to divide at will and raise his or her food.



It can be had to suit either the right or left hand, and with or without an indentation (which acts as a tooth) on the fork edge.

Messrs. Arnold and Sons, of West Smithfield, have most intelligently carried out my design.

Your kindly allowing this instrument to become known to the profession and the public through the medium of THE LANCET will much oblige—Yours faithfully,

JOHN C. HOGAN, M.B.

Sister's-avenue, Lavender-hill, S.W., 21st Jan. 1881.

THE TESTIMONIAL SYSTEM.

To the Editor of THE LANCET.

SIR,—When will the University of Edinburgh reform the method by which the majority of its professorial elections are brought about? I ask this question because it is doubtless owing to some defect in the manner in which vacancies are filled up that candidates for its chairs feel it necessary to procure and subsequently publish a whole book of so-called "testimonials." No sooner is a vacancy announced or thought of than intending candidates begin to write to all sorts of people within the United Kingdom and outside, with the view of extracting, often very unwillingly given, the miscellaneous items of which this said book of testimonials is to be composed. Surely the process is troublesome, unnecessary, and not a little humiliating to those who have to take part in it. In most other places half a dozen testimonials from those who really know the candidates are usually deemed sufficient. Why is this not so in Edinburgh? Your obedient servant,

March 7th, 1881. M.D.

GLASGOW.

(*From our own Correspondent.*)

I AM glad to notice that the managers of the Glasgow Royal Infirmary have commenced the practice of making honorary appointments to the hospital staff. The first to be so honoured is, very appropriately, Dr. Andrew Buchanan, ex-President of the Faculty of Physicians and Surgeons, who has just been elected Honorary Consulting Surgeon to the infirmary. This compliment is well deserved, and reflects credit equally on Dr. Buchanan and on the infirmary authorities.

Death has recently been busy in medical circles both in the east and west of Scotland. Edinburgh has lost Sanders, Wood, and Handyside within a comparatively short time; while Glasgow was startled by the very sudden death of Dr. J. G. Wilson on Friday last. Dr. Wilson enjoyed the confidence of his professional brethren in a high degree, and had a large practice as a consultant in obstetrics. For the chair of Midwifery in Anderson's College, rendered vacant by his death, there will doubtless be the usual scramble. It is hinted, however, that the trustees of Anderson's College may possibly leave the vacant office unfilled, in view of the talked-of amalgamation with the Infirmary School of Medicine; but as this scheme, in the present temper of the various lecturers and professors more immediately concerned, is somewhat utopian, it may be left out of consideration, and the election to the chair will therefore probably go on. This matter will be finally decided at an early meeting of College trustees.

The movement for the erection of a Southern hospital in Glasgow is making unexpectedly rapid progress. The recently appointed Executive Committee, in approaching the Town Council with the request for a free grant of land or for an offer of ground at a greatly reduced price, met with a very gratifying reception. The Council, indeed, showed a disposition to deal with the question in an extremely liberal spirit. There appears to be some objection to the site originally proposed, Coplaw-hill; but I understand that the Council have under consideration a proposal to make a grant of twenty acres or thereby of that part of Queen's-park facing Langside, for hospital purposes. Generosity such as this would give a great impetus to the scheme. The site referred to is a perfect one in most respects; it has only this drawback, that it is too far from the city proper, from the factories, and the class of people it is intended to benefit. There has been some talk also of providing Fever Hospital accommodation for the south side of the city, near or in connexion with the proposed Southern hospital; but it is to be hoped that these hospitals will be kept distinct from each other and widely separate.

Some curious facts regarding the financial position of our two existing infirmaries are set forth in a letter prepared for publication by the Executive Committee of the Southern Hospital scheme. This letter, which is designed to combat the notion that these institutions are in straitened circumstances and that Glasgow has, therefore, difficulty enough in supporting the two infirmaries she has, has been carefully gone over, and its statements and figures have been verified by the Committee; it is printed, is now in the hands of most of the influential men connected with the south side of the city, and will soon be published. It shows that during the last ten years, in a time of general commercial depression, the Royal Infirmary has not only been able to pay its way and to spend large sums on extensions and improvements, but has also saved over £50,000, and that its total accumulated stock now amounts to over £100,000. The Western Infirmary, also, during the six years it has been in existence has not only met every claim made on it, but has also saved over £16,000. This will be news to many who do not wade carefully through annual reports, and seems to prove clearly that Glasgow is perfectly able to support a third infirmary. It is much to be regretted, however, that the Committee should have thought it necessary to their case to drag the Infirmary School of Medicine into the discussion, as this is a matter which is apt to be misunderstood by the public.

Obituary.

SURGEON-MAJOR HENRY CORNISH.

SURGEON-MAJOR CORNISH, whose death from wounds received in action at Majuba Hill we recorded last week, was born at Taunton, Somerset, in 1844. He received his professional education at Edinburgh, where in 1865 he obtained the licences of the Royal College of Physicians and the Royal College of Surgeons. After passing through the course of instruction at the Army Medical School, Netley, he was appointed an assistant-surgeon on the staff of the army, his commission being dated October 1st, 1866. In January, 1867, he proceeded to Mauritius, where he served till August, 1868, when he was transferred to the Cape of Good Hope. He returned to England in 1872, and in January, 1873, was appointed to the 10th Hussars, with which he proceeded to India. He became surgeon under the Warrant of March, 1873, and was promoted to be surgeon-major in October, 1878. He continued to serve in India till the recent embarkation of troops for service in the Transvaal, where he accompanied his old regiment. He appears to have been severely wounded in the fight at Majuba Hill, and died the following day at Prospect Camp. Surgeon-Major Cornish was specially commended for his services in Afghanistan. He was deservedly much esteemed in his regiment, and in him the medical department has lost an able, zealous, and in every respect trustworthy officer.

JOHN DAY, M.D.

WE regret to announce the death of Dr. John Day, which took place at his residence, Yarra-street, Geelong, Australia, on Jan. 10th last, in his sixty-fifth year. The deceased gentleman's career was one of steady devotion to his profession. He had no brilliant qualities, but he brought to his work great earnestness, plodding perseverance, which never failed under almost overwhelming difficulties, and a fixed determination to succeed in the long run, let the time be what it might. Chemistry in its application to medicine was his favourite study. He did good service to medical jurisprudence by his discovery of the guaiacum blood-test, the value of which was at once recognised by the profession. He was an ardent believer in the therapeutic value of ozone, and contributed valuable papers on the results of his investigations to the Medical Society in Victoria.

It may interest some of our readers to know that Dr. John Day was brother to the late George Edward Day, M.D., F.R.S., formerly Chandos Professor of Medicine in the University of St. Andrews.

A GRATIFYING feature in the report read at the annual meeting of the Hull General Infirmary, held last week, was the announcement that the subscriptions during the past year received through the Working Men's Committee amounted to £609 12*s.* 6*d.*, being an increase of £72 on the sum coming from the same source in 1879. The total amount paid to the funds of the institution by this committee was £7021 3*s.* What has been done in Hull by the industrial classes may, proportionally, be done elsewhere.

Medical News.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on March 3rd:—

Guillim, Richard Davis Hoyle, Marlborough.
Jennings, Charles Egerton, Malmesbury.
Palmer, Edward Talbot, Southsea.

The following gentleman also on the same day passed the Primary Professional Examination:—

Collins, Edward Treacher, Middlesex Hospital.

University of Dublin.—The following degrees were conferred last week by the Vice-Chancellor of the University:—

Bachelor in Surgery.—Austin J. Cockle, John Robert Fraser, Thomas Charles Moore, George de Joncourt Patterson, Godfrey E. Reid, John Rynne, George Scriven, Richard C. Studdert.

Bachelor in Medicine.—John Robt. Fraser, Thomas Chas. Moore, Godfrey E. Reid, John Rynne, James Johnston Robinson.

Doctor in Medicine.—William Butler Walsh, John Fitzhenry Woodroffe.

Royal College of Surgeons in Ireland.—At a meeting of the Court of Examiners on the 23rd ult. and following day the under-mentioned gentleman was admitted a Fellow of the College:—

Henry Fitzgibbon, M.D.

The Prince of Wales has consented to preside at the forthcoming festival of the Royal Hospital for Children and Women, Waterloo-bridge-road, S.E.

John Tudor, M.R.C.S. Eng., and Alfred Emson, M.R.C.S. Eng., have been appointed Justices of the Peace for the Borough of Dorchester.

St. Mark's Ophthalmic Hospital, Dublin.—At an election last week for a resident surgeon, Mr. Stuart Davis, M.B., was appointed.

Mr. G. Dennis of Chelmsford, a short time before his decease, sent a donation of £50 each to the Infirmary and the Dispensary of the town.

The late Dr. Peele.—At a meeting of the Medical Society of the College of Physicians in Ireland, held last week, a vote of condolence with the bereaved relatives of the late Dr. Peele was adopted.

At Marlborough-street Police Court recently, two tradesmen were fined £20 and costs for selling as "butter" a kind of fat which, according to the evidence of the analyst, contained 50 per cent. of foreign ingredients.

The London Temperance Hospital, situated in the Hampstead-road, was opened for the admission of patients on the 4th inst. The Lord Mayor presided at the ceremony, and a large and influential company assembled on the occasion.

The Buckingham Board of Guardians have appointed a committee to investigate the mode in which medical relief is administered in the union. The committee is to make special inquiry as to the number and working of village clubs in relation to the medical aid distributed in the parishes.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* The Lancet *before 9 o'clock on Thursday Morning, at the latest*

Beamish, W., M.D., L.R.C.S.Ed., has been reappointed Senior Physician to the Cork Fever Hospital.

Boulton, P., M.D., L.R.C.S.Ed., M.R.C.P.L., has been appointed Physician to Out-patients, Queen Charlotte's Lying-in Hospital.

Budds, W. T., L.K.Q.C.P.I., L.R.C.S.I., has been reappointed Physician to Out-patients of the Cork Fever Hospital.

Campbell, W., L.R.C.S.Ed., L.S.A.L., has been appointed one of the Medical Officers of the Hastings Free Dispensary.

Colborne, H., M.R.C.S.E., has been appointed one of the Medical Officers of the Hastings Free Dispensary.

Crowe, J. W., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Honorary Physician to the Hartlepool Hospital.

Field, J. W., M.R.C.S.E., L.R.C.P.Ed., has been appointed Assistant-Surgeon to the Tewkesbury Hospital, vice C. Penruddock, resigned.

Hoskyn, D. T., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Presteigne District of the Knighton Union.

Houghton, W. B., M.D., M.R.C.P., has been appointed Lecturer on Forensic Medicine at Charing-cross Hospital, vice Irvine, deceased.

Jenkins, J. H., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Sixth District of the Liskeard Union.

Jenkins, T. G., L.R.C.P.Ed., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Second District and the Workhouse of the Ruthin Union, vice Dr. J. R. Jenkins.

Jones, H. M., M.D., F.R.C.S.E., has been reappointed Physician to the Cork Fever Hospital.

Kirby, T. C., L.K.Q.C.P.I., M.R.C.S.E., has been appointed Consulting Physician to the North-West London Free Dispensary for Sick Children, Bell-street, Edgware-road, W.

Macdonald, C. R., M.B., C.M., has been appointed Medical Officer for Barkip Coal and Iron Works, Barr Thread Mills, and Barr Colliery, Ayrshire, vice Morison, deceased.

Morison, J. R., M.B., F.R.C.S., L.R.C.P.Ed., has been appointed Honorary Physician to the Hartlepool Hospital.

Searle, G. C., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Brixham District of the Totnes Union.

Shorter, H. G., M.R.C.S.E., L.S.A.L., has been appointed one of the Medical Officers of the Hastings Free Dispensary.

Soper, R. W., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Borough of Dartmouth.

Thompson, A. H., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Great Ouseburn District and the Workhouse of the Great Ouseburn Union.

Wigmore, J., M.D., has been appointed Medical Officer for the Sixth (Tiverton-on-Avon) District of the Bath Union, vice Barrett.

Births, Marriages, and Deaths.

BIRTHS.

Alabone.—On the 27th ult., at Lynton House, Highbury New-park, the wife of Edwin W. Alabone, M.D., of a son.

Bate.—On the 4th inst., at Northumberland Houses, Hackney, the wife of George Paddock Bate, M.D., of a daughter.

Butler.—On the 6th inst., at Cromwell-road, South Kensington, the wife of E. R. Butler, M.D., of a daughter.

Farr.—On the 1st inst., at Earl's Court-road, Kensington, the wife of F. Arthur Farr, L.R.C.P.Ed., of a daughter.

Giffard.—On the 4th inst., the wife of H. E. Giffard, Esq., M.R.C.S.E., L.S.A.L., of Denham House, Egham, of a son.

Jackson.—On the 7th inst., at Park-lane, Tottenham, the wife of G. Henry Jackson, Surgeon, of a son.

McDonald.—On the 7th inst., at Southall, Middlesex, the wife of George Bruce McDonald, M.D., of a daughter.

Milne.—On the 2nd inst., at Accrington, the wife of Thomas Milne, M.A., M.D., of a daughter.

MARRIAGES.

Bishop—Bird.—On the 8th inst., at St. Lawrence Church, Barton-on-the-Heath, Warwickshire, by the Hon. and Rev. Walter R. Verney, assisted by the Rev. Arthur Nettleship, Rector of the Parish, John Bishop, M.D., F.R.C.S.E., of Edinburgh, to Isabella Lucy, daughter of the late Rev. Edward Bird, Rector of Wyton, Huntingdonshire.

Gardner—Atherton.—On the 1st inst., at St. James's Church, Suffolk-square, Cheltenham, Robert H. Gardner, M.D., Army Medical Staff, to Sophia Philippa, eldest daughter of C. B. Atherton, Esq., of Taynton, Gloucestershire.

Reynolds—Crespigny.—On the 8th inst., at St. Margaret's Church, Westminster, by the Very Rev. the Dean of Westminster and the Rector, the Rev. Canon Farrar, D.D., J. Russell Reynolds, M.D., F.R.S., of Grosvenor-street, to Frances, widow of the late Charles John Champion Crespigny, Esq., and eldest daughter of the late William Plunkett, Esq., Barrister-at-law.

Truman—Herring.—On the 8th inst., at St. James's, Piccadilly, Charles Edwin Truman, Esq., M.R.C.S.E., M.A., to Charlotte Fanny, only child of the late William Herring, Esq., of Putney.

Van Geyzel—Palmer.—On the 1st inst., at St. Andrew's Episcopal Church, Aberdeen, John Lawrence Van Geyzel, M.B., C.M., Surgeon in Her Majesty's Indian Medical Service, eldest son of J. A. Van Geyzel, of Colombo, Ceylon, to Catherine Alice, eldest daughter of W. J. Palmer, of Albury-road, Aberdeen.

DEATHS.

Dempster.—On the 27th ult., at Duncannon, near Waterford, James Carroll Dempster, M.D., Deputy Surgeon-General.

Earle.—On the 28th ult., at Warbeck-road, Shepherd's-bush, Frederic J. Earle, M.D., Surgeon-Major Her Majesty's Bengal Army, aged 53.

Foster.—On the 26th ult., at Park-place, Leeds, Edwin Foster, L.R.C.P.L., aged 73.

Godrich.—On the 7th inst., at Fulham-road, of apoplexy, Francis Godrich, M.R.C.S.E., aged 85.

Landon.—On the 27th ult., killed in the action on the Majuba Hill, South Africa, Arthur Jermyn Landon, Surgeon, Army Medical Department, second son of the late Francis Newcombe Landon, Esq., of Brentwood, Essex, aged 29.

Richards.—On the 7th inst., Samuel Richards, M.D., of Bedford-square, in his 73rd year.

Thornton.—On the 4th inst., suddenly, at his residence, Bank Lodge, Scarborough, William Henry Thornton, M.D., F.R.C.S.E., J.P., deeply regretted, aged 55. Friends will kindly accept this intimation.

Truman.—On the 2nd inst., suddenly, at New Basford, Notts, Samuel John Truman, M.R.C.S.E., son of the late Beckit Truman, of Nottingham, aged 35.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, March 14.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — 4 P.M. Professor W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Cetacea."

MEDICAL SOCIETY OF LONDON.—8.30 P.M. The President's (Dr. Broadbent) Opening Address.—Dr. T. Stretch Dowse will show a Case of Pseudo-Hypertrophic Paralysis.—Mr. W. Spencer Watson, Two Cases of Unusual Affection of the Nose.—Mr. T. Gilbart Smith will exhibit a Specimen of Embolism in the Kidney in a Case of Heart Disease.

Tuesday, March 15.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Edward A. Schäfer, "On the Blood."

LONDON INSTITUTION.—8 P.M. Professor De Chaumont, "On Sanitary Assurance."

PATHOLOGICAL SOCIETY OF LONDON.—8½ P.M. The following specimens will be shown:—Relations of Disease of Nipple and Areolar Cancer of the Breast; Cystic Degeneration of Breast; Cystic Disease of Kidneys and Liver; Cystic Disease of Ovary from a Fœtus; Aneurisms of Aortic Valve (card); Cancer of Mediastinal Glands and Pleura; Localised Pneumothorax; Thrombus in Pulmonary Artery; Cranium and Brain of Hydrocephalic Adult; Villous Polyp of Bladder; Arrested Development of Upper Limb (card).

Wednesday, March 16.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — 4 P.M. Professor W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Cetacea."

ROYAL COLLEGE OF PHYSICIANS OF LONDON. — 5 P.M. Gulstonian Lectures: Dr. Coupland, "On Anæmia."

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.—7.45 P.M. Communications from Mr. Edward Bartlett, &c.—Council Meeting.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND SCIENCES.—Mr. T. P. Bruce Warren, "On the Manufacture of Aërated Waters."

Thursday, March 17.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

ROYAL INSTITUTION.—3 P.M. Mr. H. H. Statham, "On Ornament."

HARVEIAN SOCIETY.—8½ P.M. Mr. Bryant, "On a Case of Gastrostomy for Cicatricial Stricture of the Œsophagus."—Dr. Gowers, "On the so-called Tendon-reflex Contractions."

Friday, March 18.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1¼ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — 4 P.M. Professor W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Cetacea."

ROYAL COLLEGE OF PHYSICIANS OF LONDON. — 5 P.M. Gulstonian Lectures: Dr. Coupland, "On Anæmia."

ROYAL INSTITUTION.—8 P.M. Dr. W. H. Stone, "On Musical Pitch."

Saturday, March 19.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Rev. H. R. Haweis, "On American Humorists."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE INDEX MEDICUS.

THIS is a monthly classified record of the current medical literature, in all languages, of the world. It is published in New York, by F. Leypoldt, who, in his announcement, states that whether it shall be continued after the completion of this, its second year, rests with the medical profession to decide. As a classified universal work of reference for medicine and its allied sciences, this is by far the most complete and exhaustive index ever issued. It has not alone the merit of giving the titles of all books by all authors, but, further, it gives the titles of the more important contributions to periodical medical literature in all languages. Many a busy provincial or colonial practitioner would find a copy of it useful to enable him to select suitable books for any special subject which might interest him.

Delta.—A certificate under the Vaccination Acts must be signed by a duly registered medical practitioner. Complaint should be made to the Local Government Board.

"OPENING OF MUSEUMS AND PICTURE GALLERIES ON SUNDAYS."

To the Editor of THE LANCET.

SIR,—In your issue of this date you notice with approval the signature by medical men of an address to the Premier in favour of opening the British Museum on Sundays. If you can spare space, will you allow me to point out the great boon to students that the opening of such institutions would be? Few will doubt that the better the general education a medical student gets, the more successful as a general practitioner and the more useful as a member of our faculty is he likely to prove subsequently. I need only mention how a student who fairly attends to his work has his time taken up to show that he has not time on week days—during the sessions at least—to visit museums, picture galleries, &c. In the first part of his course, lectures, demonstrations, and dissections are sufficient to occupy most of his daylight hours, leaving him his "studying" to do during the evenings. During the subsequent stages of his studentship ample occupation for working days will be found in ward work with the house officers in the morning, attendance in the out-patient rooms and sundry special departments at mid-day, and "going round" with the visiting officers in the afternoon, together with lectures, &c., at odd times as they can be made to fit in, and private study at night.

May I suggest, then, that an address to the Premier in favour of a "Rational Sabbath" from students at the London hospitals would not be inappropriate. Having but lately arrived in England, I am scarcely suited for organising this, but trust that some energetic friend of an unpopular, but not wholly undeserving, section of the community may be induced to act. I am, Sir, yours obediently,

St. Thomas's Hospital, March 5th, 1881. A STUDENT.

"THE RIGHT HON. LYON PLAYFAIR."

THE following choice *morceau*, from the February number of *Gaillard's Medical Journal*, will be interesting to cis-Atlantic medical readers:—

"Such is the manner in which the London *Times* alludes to Dr. Playfair, the distinguished obstetrician, who in the existing debates, recently occurring in the British House of Commons, was made deputy speaker of that body. The author of Playfair's midwifery is as remarkable for his humour as he is for his medical erudition. It seems that in the debate Mr. Millbank (a member) termed Mr. Biggar (also a member) 'a scoundrel.' The speaker, Dr. Playfair, being appealed to to preserve order, ruled that 'it was the duty of Mr. Millbank to apologise to the House for calling Mr. Biggar a scoundrel, but not to Mr. Biggar.' Mr. Millbank then made his apology 'in accordance with the mode prescribed by the speaker.' It was a delivery in three stages."

Dr. W. Alexander.—The paper will appear in an early number.

Obstet.—We think such services should be freely rendered by one medical man to another, whether he be principal or assistant. We are all more or less dependent on each other's good offices.

An Old Subscriber.—There can be no doubt as to the character of the handbill being most unprofessional, but we must decline to be the medium of further publicity of such an announcement.

Mr. Baber (Brighton).—As early as possible.

Dr. A. V. Ford will find the matter commented on in another column.

Dr. Wynn Williams' letter will appear in our next.

A Disgusted One complains strongly, but not too strongly, of unlicensed practitioners. He will see that we elsewhere direct attention to the subject.

INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—As a constant reader of THE LANCET for the past year, I have felt very much distressed by the hostile tone adopted towards the Indian Medical Service in their struggle for the redress of some of their grievances. I had confidently expected sympathy and assistance from the leading professional organ. May I ask you to publish "a round unvarnished tale" of the first two years' experience of a young surgeon, and leave it to be decided by any impartial reader, acquainted with the promises made to us before entering the service, whether we are not most unjustly treated.

On arriving in India I was at once sent to Afghanistan, where I served for about five months in cholera and field hospitals on "unemployed pay," 286 rupees per month. I then got medical charge of a regiment whose surgeon was sent sick to England, and got—not full pay, 450 rupees—but 386 rupees per month, though about 70 per cent. of the men were on the sick-list when I took charge. I remained in charge of this regiment while it was on service and near the frontier (about a year), but when it was sent down to a comfortable cantonment, and the cold weather came on, I was relieved from the charge and ordered to "do duty" with the regiment on unemployed pay. I have been thus engaged for the past two months, and will probably continue so till the stifling heat of the plains obliges some of the less robust of my brother surgeons to take refuge in the hills or in England. Though "unemployed," I have, in addition to regimental duty, garrison inspection work, and in my turn have to attend brigade parades and field exercises mounted.

There is not a single combatant officer in the Indian army serving with native troops whose pay is anything near so small as mine. A subaltern in the regiment of eighteen months' total service in England and India gets 325 rupees, and most of them considerably more. It is, therefore, idle to think that we can be satisfied by the useless grant of captain's relative rank when we get considerably less pay than the youngest subaltern serving with us as probationer for the staff corps. Government takes advantage of our powerlessness, and it is "the most unkindest cut of all" when THE LANCET exerts its influence against us, and hints that we are querulous grumblers.

When I apply some of the principles laid down in the article on "The Commercial Aspects of Medicine," which appeared in THE LANCET of Jan. 1st, to my case, my professional pride is not flattered by the reflection that Government values the services of a subaltern of eighteen months' service at a higher rate than it does those of an

India, Feb. 6th, 1881. M.B., B.A.

⁂ Our correspondent must have read THE LANCET for the past year to little purpose if he has come to the conclusion that it has adopted a hostile tone towards the Indian Service. We have endeavoured to bring clearly before the authorities and the profession the grievances under which it labours, and have urged the adoption of measures for their removal. Some of these have already been brought into operation, and we trust the rest will soon follow. But we have steadily refused to recognise the claim put forward by some of the advocates of the Indian Service, that they should retain half of the military administrative appointments, and receive also all those civil ones which were created to compensate them for the loss of the others. We have, in fact, objected to a great addition being made to the prizes of the Indian at the expense of the British Medical Service. If our correspondent is still "very much distressed" by his view of our conduct, we recommend him to re-peruse our leader of October 2nd.—ED. L.

B. H. H.—1. It would be the medical officer of health's duty to advise the managers and master or mistress of the school of the course they should take under the circumstances.—2. No; itch is not included under "dangerous infectious diseases."—3. No.

Mr. J. Lockhart Gibson.—We must decline to comply with our correspondent's request.

THE FULHAM SMALL-POX HOSPITAL.

To the Editor of THE LANCET.

SIR,—Mr. Edmund Tattersall sends the general press particulars inculpating the Fulham Small-pox Hospital as a focus for the dissemination of small-pox over the immediate neighbourhood. Kindly allow me to add the following corroborative statistics drawn from my own district (Brompton), which does not form quite half the "entourage" of the hospital.

During the last three years ending Dec. 31st, 1880, 213 pauper cases were sent into the hospital from my district, of which 124 came from within the quarter-mile radius directly adjoining the hospital (which, be it remarked, is not entirely covered with dwellings, quite two-thirds being open ground), 55 from between the quarter and half-mile radius, and the remaining 34 being scattered over the remainder of the district, which extends to a distance of two miles from the hospital.

During one of the outbreaks in my district cases were removed within a period of three days from fifteen different thoroughly well built and respectable streets. This remarkable simultaneity of outbreak undoubtedly implies a simultaneity of action from some great infecting centre, which cannot be explained otherwise than by the action of the Fulham Small-pox Hospital.—I am, Sir, your obedient servant, FRANCIS GODRICH,

Medical Officer, Brompton District, South Kensington, S.W.

Fulham-road, March 4th, 1881.

⁂ We regret to announce the death of the writer of the above letter, the oldest medical practitioner in Chelsea and officer of health for the parish. He attended the meeting at the Vestry Hall on Monday last, the 7th inst., against the Fulham Small-pox Hospital. He made a short speech, detailing statistics extending over many years, and showing that the hospital was a centre of contagion. A medical speaker having in the course of his reply impugned the statistics adduced by Dr. Godrich, the deceased gentleman became very excited, and was attacked with apoplexy. He did not recover consciousness, and died the following day, Tuesday, March 8th, at 5 P.M.—ED. L.

TREATMENT OF PLEURISY AND EMPYEMA.

To the Editor of THE LANCET.

SIR,—I have read with pleasure in THE LANCET of Feb. 26th and March 5th the excellent article of Dr. Morgan on the "Treatment of Pleurisy and Empyema," not only on account of the scientific manner in which he treats his cases, but I have personally had an opportunity of observing some of his successful results. Yet it has always struck me that the method of re-expanding the lung by directing the patient to inhale compressed air from "Seigel's pneumatic apparatus" must constitute an important factor in the etiology of vesicular emphysema, when we remember that there is already a tendency to the production of what has been termed by some writers "vicarious emphysema." When the lung being bound down by pleuritic adhesions, and therefore rendered partially or entirely incapable of expansion, the air which ought to enter these unused portions passes into other parts and unduly stretches their vesicles.

I am, Sir, yours respectfully,

Wigan, March 6th, 1881. W. MITCHELL ROOCROFT, M.R.C.S.

Subscriber.—It may be obtained through Trübner and Co., Ludgate-hill.

Adviser.—We do not prescribe.

Spes.—Replies to our correspondent's numerous and elaborate inquiries would occupy more space than we have at our disposal for such a purpose.

SUPRA-PUBIC CYSTOTOMY.

To the Editor of THE LANCET.

SIR,—When THE LANCET gives the high authority of its commendation to the consideration of an operation, it is sufficient evidence of its value, and necessarily commands the respectful attention and notice of the profession which it represents and whose opinions it guides.

I will make a reference, with your kind permission, to only one of the conditions you mention under which the "high operation" has been recommended—namely, when the stone is large and a hard one. Surely, Sir, when the stone is a large one, the opening required for its removal must, from its extent, prove a very serious obstacle, and I should like to know what means could be adopted to overcome this difficulty, at the same time that a speedy operation could be ensured.

Physiologists give us examples to show that nature will make bodies pass through openings smaller than themselves to accomplish her purposes without injurious results. But this is an accomplishment that modern surgery, with all its brilliant triumphs, has never effected, nor of course is likely to effect, at least not as regards the removal of a large hard calculus from the upper part of the bladder, and where indeed every line of space is important, and every degree of movement may mean disappointment and destruction.

I am, Sir, your obedient servant,

Feb. 24th, 1881. MEDICUS.

"THE WELBECK POISONINGS."

To the Editor of THE LANCET.

SIR,—Since reading the account of Dr. Ballard's investigations into the cause of the epidemic in connexion with the Welbeck sale, in which he says that the investigation "showed the existence of a species of bacillus, experiments with which, made upon animals, produced pneumonia," it has occurred to me to suggest, through the medium of your valuable journal, that the morbid matter mentioned is the blood poison belonging to whooping-cough.

On September 2nd, 1879, a very intelligent man called upon me, and, in the course of conversation, told me his pig had died two or three days before. I asked him the cause of death, as my attention has been given to investigating whooping-cough for the last ten years. He ascribed it to typhoid fever, and, on my asking for symptoms, said it began with diarrhœa, refusal of food, and slight fever; then head symptoms appeared, the animal when lying down rolling its head from side to side, and dashing it on the ground. I asked him if there was any cough. He said "Yes," its cough was so violent that it seemed to fall down with it; there was also dyspnœa, and finally it died in convulsions. I was sorry that I had not seen the pig both before and after death, as the symptoms plainly indicated congestion of brain and lungs (pneumonia), both due, in my opinion, to the poison of whooping-cough, and were such as I had seen in several patients. Had the pig belonged to a drove the others would most likely have suffered in the same way, or, if stronger, the poison might have remained dormant until some change of air, place, or other circumstances had developed it, and persons eating their flesh might have suffered.

On August 30th, 1880, a gentleman came to the house of a patient to consult me. He had been at the Welbeck sale, had eaten some of the ham, and suffered for some days after from diarrhœa and stomach irritation, but, to use his own words, "he had not felt well since that time." I examined him carefully, and found the following symptoms:—A feeling of general malaise, increasing towards night; sleeplessness, giddiness on looking either up or down; a tendency in walking suddenly to run off to one side; slight pulmonary irritation, which he described as being rather asthmatical. All these symptoms are found in persons who have been exposed to the whooping-cough poison. I prescribed for him with that opinion, and did not see him again till Jan. 2nd, when he told me that the treatment had quite removed his symptoms, and that he had been quite well.

From these and many other cases I have come to the conclusion that whooping-cough is a disease depending upon a peculiar blood poison, which is exhaled and absorbed by the bronchial and pulmonary mucous membrane, and not a mere spasmodic cough belonging to infancy and childhood, or that it may be taken into the system by eating the flesh of any animal infected with it. That it may lie dormant in the system even for months, and that, when developed, assumes many forms—viz., pneumonia, often called congestion of lungs; meningitis, cerebro-spinal meningitis, or typhoid pneumonia, as it has been called; low remittent fever, with exacerbations every night; inflammation of joints, very much resembling rheumatic fever, and moving quickly from one joint to another; congestion of uterus and ovaries, the ovaries particularly; also what is generally called winter-cough, and a peculiarly rapid form of consumption. In animals I believe that the disease generally called pleuro-pneumonia is due to the same blood poison, which explains its being so contagious, and also it may cause what has been called typhoid fever in pigs. These facts can be supported with cases.

I have not Dr. Ballard's address, or would have written to ask him what form of pneumonia was produced in the animals experimented upon, the pneumonia of whooping-cough being catarrhal or inflammation of the pulmonary mucous membrane, and not of the substance of the lung.

With an apology for trespassing so much on your valuable space, I remain, yours very truly,
JOHN COLSTON.

New Whittington, March 7th, 1881.

X. Z.—In reply to our correspondent's complaint, it may fairly be said that the preliminary examination hitherto conducted by the Royal College of Surgeons was instituted for candidates for its own diplomas, and not for the convenience of persons seeking to obtain qualifications from other examining bodies.

Gulstonian Lectures
ON
ANÆMIA.

Delivered before the Royal College of Physicians,

By SIDNEY COUPLAND, M.D., F.R.C.P.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL.

LECTURE I.—Part I.

Impoverishment of Blood with regard to Hæmoglobin the essential fact in Anæmia—This may be Quantitative or Qualitative—Analysis of Blood in Chlorosis—Methods of Estimation of Hæmoglobin—Malassez, Hayem, Gowers, Quinquad—The Red Corpuscles: Variations in number, size, and form; their development, destruction, and renewal—Share taken by Lymphatic Glands, Spleen, Bone-marrow, and Liver (?) in the work of Blood Formation—The Hæmatoblasts of Hayem.

Mr. President and Gentlemen,—In selecting as the subject of these lectures which I have the honour of delivering before you a condition so commonly and widely prevalent as Anæmia, I fear that I have undertaken a task which is not easy of fulfilment. For around this subject there clings much obscurity, owing to our lack of knowledge; and it would require far more profound analysis than I can hope to give to illumine its dark places. I do not bring you any original researches, and I cannot discuss the question in all its bearings; but if by a simple exposition of what I conceive to be the directions in which the solution of its problems lie I can fulfil a useful purpose, I shall be satisfied. For the subject is one worthy of attention; and in this College where the memory of Harvey, the student of the circulatory mechanism, is ever kept green, it is surely fitting that we should now and again review our knowledge of those conditions in which the blood plays so prominent a part. It is a truism to say that the integrity of the blood is essential to the performance of healthy function; and as disease is in great measure only disordered function, it is plain that such disorder may be determined by, as it must determine, changes in the circulating medium itself. There are some diseases in which defects in the blood stand out in sharp relief, but the more deeply the nature of disease is inquired into, the more clearly is it manifest that the blood—the mobile tissue pervading every part of the organism, and essential for its proper working—must be modified by any departure from the normal. The modification thus induced may be almost infinitesimal—it may be, in a sense, simply necessary to maintain the life of the individual when placed under abnormal conditions; or it may be so profound as seriously to interfere with the vital processes, and be the ultimate if not the proximate cause of death. Thus in anæmia we pass insensibly over the margin of health to disease—to the very confines of the latter's territory—the limit placed by death.

Naturally the greatest interest—for here lies the deepest obscurity—centres in the etiology of this condition, and my object to-day will be to consider facts concerning the blood and the part it plays in the economy with the view of illustrating the varied manner in which the anæmic state may be brought about. Without attempting to give a definition of anæmia other than that it is a condition of the blood in which its composition is so defective that it cannot sufficiently fulfil its respiratory and nutritive functions—implying, that is, a lowering of its standard composition in those elements which are destined to promote oxidation, to accelerate tissue-change, and repair tissue-waste—I must in the first place say a little concerning the blood itself, and in doing so must crave indulgence for venturing to repeat facts so well known.

The blood consists of the fluid part or plasma and the formed elements or corpuscles, the latter constituting rather more than one-third of the whole by weight. The corpuscles contain about 50 per cent. of water, their main solid constituent being the albuminoid crystallisable substance hæmoglobin associated in the coloured corpuscles with a minute quantity of iron, between 0·4 and 0·5 per cent. The serum, on the other hand, is composed of 90 per cent. of water, 8 to 9 per cent. of proteids, and 2 to 1 per cent. of fats, extractives, and saline matters (Foster). Then there is the curious circumstance in the inorganic constituents—viz., the preponderance of potash salts and phosphates in the corpuscles as compared with a parallel excess of soda salts and chlorides in the serum. (See Tables I. and II.)

Table I.—*Mean Chemical Composition of Blood.*
(Becquerel and Rodier.)

	In Health.		In Chlorosis.
	Adult Male.	Adult Female.	
Water	780	791	828·2
Solids	220	209	171·8

Solids	98·49	Fibrin	8·06		
		Album. & extr.	81·92		
		Salts	8·51—viz.,		
				Pot. chlorid.	0·559
				Sod. chlorid.	5·546
				Sod. sulph...	0·281
				Sod. phosp...	0·271
				Sod. carb. ...	1·532
				Calc. phosph.	0·298
				Mag. phosph.	0·218

Corpuscles. (Schmidt.)

1000 parts contain :

Water	618·63				
Solids	318·37	Hæmatin	15·02		
		Globulin	296·07		
		Salts	7·28—viz.,		
				Pot. chlorid.	3·679
				Pot. phosph.	2·343
				Pot. sulph...	0·132
				Sod. phosph.	0·693
				Sod. carb. ...	0·134
				Calc. phosph.	0·094
				Mag. phosph.	0·160

Analyses show, therefore, that the corpuscular elements form the greater part of the solids of the blood, and it thus follows that the hæmoglobin is by far the most abundant of its albuminoid constituents.

True anæmia of course implies a diminution in all these blood constituents—a condition only obtaining, and that in a transitory manner, after profuse and sudden hæmorrhage, the quantity of fluid lost being made up by a rapid osmosis of water from the tissues. The blood in that case becomes hydræmic, as it may do in the later stages of a chronic anæmia where there has been loss or destruction of the albuminoids of the serum. The consideration of such rapid and extreme forms of anæmia as those produced by sudden and severe hæmorrhage does not enter into my programme, except as serving to illustrate the various phases of anæmia, whether primary or secondary. The most marked fact in such anæmia is the impoverishment of the blood in its albuminous constituents, especially in the hæmoglobin—an impoverishment which may be owing to an actual diminution in the quantity of this substance, but which is also very probably due to a qualitative change in it, whereby it is rendered unable to subserve its chief office, that of conveying oxygen to the tissues. At present there is but little known concerning this latter modification.[1] Attention has been mainly directed to the alterations in *amount* of hæmoglobin and of the albuminoids, and it is found that the diminution in these constituents is accompanied to a definite, but a comparatively small, extent by an increase in the saline matters, and generally also by an increase in the water of the blood. I have placed before you (Tables III. and IV.) certain analysis of blood in *chlorosis*, which show that in that form of anæmia, at any rate, the reduction of solids is mainly in the corpuscular part of the blood, and *not* in the serum; and there are abundant analyses made in more recent days which show that the reduction is almost entirely that of the hæmoglobin. The contrast between this deficiency and the normal, or even excessive, amount of serum-albumen in this disease has been adduced as evidence of the essential difference between this form of anæmia and other forms. It seems doubtful, however, whether it is wise to base the distinction upon such a narrow ground as this, seeing that in the all-important feature of anæmia—that of deficiency of hæmoglobin,—chlorosis takes the chief place.

---

[1] It has been lately argued with much force by Drs. M. P. Jacobi and White (Archives of Medicine, 1880) that in anæmia the organised albuminoids of the body, including the corpuscular hæmoglobin, are all functionally inactive, and are rendered unable to condense oxygen and to store albumen in sufficient quantity for the needs of the organism. This is the most explicit statement, I know of, of the view that the change in the hæmoglobin may be not simply a quantitative, but a *qualitative*, one.

TABLE III.—*Mean Composition of Blood* (*1000 parts*).

	IN HEALTH. (LECANU.)	IN CHLOROSIS. (ANDRAL & GAVARRET.)	
		Incipient.	Fully developed.
Water ...	790·0	801·0	853·2

Corpuscles ...	49·29	78·73	85·79
Solids of serum	82·91	83·53	82·03
	(Salts, 7·54.)		(Salts, 8·203.)

So important is this constituent that in endeavouring to analyse the etiological side of anæmia, and to explain the effects of the condition, inquiry may be almost concentrated upon the variations of hæmoglobin to the exclusion of the other blood elements. Consequently many methods have been devised for determining as accurately as possible the absolute and relative quantities of hæmoglobin in the blood. These methods severally consist in (1) the determination of the amount of iron in the corpuscles, it being found to be in constant proportion to the amount of hæmoglobin; (2) in the spectroscopic appearances given by solutions of hæmoglobin of various degrees of concentration; (3) in the absorptive capacity of a given quantity of blood for oxygen; and (4) in the comparative determination of the amount of colouring matter by contrasting a solution of blood of known strength with certain standard colours or coloured substances corresponding to the tint of a solution of normal blood. This last is the simplest and readiest of all the methods, although not quite as accurate as some of the others where larger quantities of blood are dealt with. It is to Messrs. Hayem and Malassez that we owe the introduction of these methods, and the simple apparatus devised by Dr. Gowers modifying the latter's method is before you. I have placed on the table specimens of blood of different degrees of anæmia, illustrating this method, where the standard of comparison represents the colour of 20 c.mm. of normal blood diluted 100 times. In that way the percentage amount of hæmoglobin may be estimated, but the absolute quantity has been determined by some of the other methods. Of these I may especially mention that carried out by Quinquad, who, availing himself of the reducing properties of sodic hydrosulphite was enabled to calculate the maximum quantity of oxygen capable of being absorbed by a given sample of blood. The mean capacity in health, he found, was 240 cubic centimetres of oxygen to every 1000 grammes of blood, and as estimations by iron show that hæmoglobin contains 0·43 per cent. of that metal, and that 1000 grammes of blood contained 0·53 grammes of iron, it follows that the quantity of hæmoglobin capable of absorbing the above amount of oxygen must be 128 grammes. (See Table V.) M. Quinquad has therefore assumed that hæmoglobin invariably has this absorptive capacity for oxygen, and has applied this method of determination to estimate the hæmoglobin in various diseases. In the main his results accord with the older and more elaborate analyses, as well as with those obtained by the colour-methods. For example, he found that in chlorosis the hæmogoblin suffers absolute diminution to a greater extent than in any other disease, except pernicious anæmia and cancer, but that the solid matters of the serum were very slightly if at all reduced—a result similar to that I have recently quoted.. The obvious objection to the method is that it does not allow for alterations in the quality of the hæmoglobin of a given specimen of blood, which would alter its capacity for absorbing oxygen. Another difficulty arising in regard to most of the methods of absolute determination lies in the discrepancies liable to creep in in the minute calculations they involve, a criticism which applies with equal force to all methods of blood-numeration and analyses of small quantities of blood. Thirdly, all these methods are imperfect in that they, of necessity, tell nothing of the total amount of the blood, which may be much impoverished as a whole, but which, owing to alterations in density may apparently yield a normal or even excessive amount of colouring matter and corpuscles. These points were well illustrated in a recent paper by Drs. Baxter and Willcocks,[2] and enforce the lesson that the results of these methods of estimation can only be dealt with in a relative sense; and that a very slight deviation may lead to great error in the total result.

TABLE V.—*Estimation of Hæmoglobin and its capacity for Oxygen. Mean of four observations.*
(QUINQUAD.)

	Amount of Hæmoglobin in 1000 cc. of Blood.	Amount of Oxygen absorbed by 1000 cc. of Blood.
Adult male ...	130 grms.	250 cc.
Adult female ...	114·2 grms.	225 cc.
Old man	105·8 grms.	205 cc.

It is impossible, however, to deal with alterations in hæmoglobin without inquiring into the natural history of the red corpuscles themselves, which are so largely composed of this substance. This we may now proceed briefly to consider. We may expect to find variations in the number, size, form, and evolution of those elements to be associated with the anæmic state; for in general terms this state depends either on a numerical deficiency in these corpuscles, or a deficiency in their hæmoglobin, or on both these conditions.

The number of coloured corpuscles in a cubic millimetre of blood is on an average 5,000,000 for the adult male, and 4,500,000 for the female. These figures, originally calculated by Vierordt and Welcker, have been confirmed of late years by the process of numeration by means of the hæmocytometer invented by Hayem and introduced into this country in a modified form by Dr. Gowers. Their precise accuracy has been questioned, some asserting that they are too high, others that they are too low—discrepancies depending partly, perhaps, on instrumental errors and partly upon the variations which occur in the healthy subject in relation to food, to the greater or less concentration of the plasma, to the region from which the blood is taken, or the state of contraction of the vessel yielding it. At the same time these figures represent sufficiently well the average of health, and serve well enough as standards of comparison. Mere numeration, however, is misleading as an indication of the blood value; the hæmoglobin also must be taken into account, and we can hardly have a better example than in chlorosis, where, with a much diminished quantity of hæmoglobin, the number of corpuscles is often but slightly, if at all, below the normal. It has, therefore, been an object to determine the actual quantity of hæmoglobin falling to each corpuscle. Malassez especially has attempted this, so as to express the corpuscular richness in terms of hæmoglobin, and the hæmoglobin in terms of corpuscular richness (Table VI.), and he has quite lately further perfected his method, whereby it can be clearly shown the corpuscles in pathological conditions may contain a greater proportionate

TABLE VI.—*Hæmoglobin and Corpuscles.* (MALASSEZ.)

amount of hæmoglobin than in health, and the converse. He has shown also that the size of the corpuscle does not determine the amount of the hæmoglobin either in the animal series or in disease in man (see Tables VII. and VIII.)

TABLE VII.—*Hæmoglobin and Size of Corpuscles.* (MALASSEZ.)

	Amt. of Hæmoglob. per Corpuscles.	Size of Corpuscles.	Amt. of Hæmoglob. per 1 μ cub. of Corp. Subst.
Man	30 μμ gr.	72	0·416 μμ gr.
Pigeon	52 ,,	125	0·416 ,,
Lizard	70 ,,	201	0·348 ,,
Frog	216 ,,	629	0·343 ,,
Proteus	1066 ,,	9200	0·115 ,,

TABLE VIII.—*Hæmoglobin and Size of Corpuscles.* (MALASSEZ.)

	Richness in Hæmoglobin.		Diameter of Corpuscles.	
	Absolute.	Relative.	Absolute.	Relative.
Cancer	13 μμ gr.	0·43	6·64	0·87
Chlorosis	22·7 ,,	0·75	8·29	1·09
Normal	30 ,,	1·0	7·60	1·0

Changes in corpuscular value are seen whenever one calculates the number of corpuscles and estimates the quantity of hæmoglobin; but although in one specimen 4,000,000 corpuscles with a percentage of 30 of hæmoglobin will be equivalent to 2,000,000 with 60 per cent., as regards the total quantity of colouring matter; it must be borne in mind that the respiratory or nutritive value—in other words, the functional value—of the one may be greater than the other owing to the difference in the number of the elements, or to difference in their size.

The size of the coloured corpuscles (diameter of $\frac{1}{3500}$ to $\frac{1}{3200}$ of an inch or 7·7 μ.) is a tolerably constant quantity in health, but in anæmic conditions it is common to find very many corpuscles much below the averages. The smaller spherical coloured elements, which have received the name of microcytes, are often abundant in anæmic blood. They may represent immature forms of the red corpuscle; and I shall have to mention yet smaller elements, upon the presence of which great stress is laid by M. Hayem in speaking of the development of the blood. More than one authority has declared that the corpuscles in chlorosis are larger than those in health, and that in cancer they are plainly smaller—changes which, if occurring, might be related to the nature of the intimate substance of the corpuscle, where also may be found explanations for changes in form as well as size.

For the characteristic discoid shape is (except in the case of the microcytes just mentioned) very little altered in the living state, although after removal from the body, under the influence of reagents, &c., they undergo many changes of shape. Considerable, and perhaps undue, stress has been laid upon the form-changes in corpuscles in the severe cases of idiopathic anæmia, of which they have been made almost a pathognomonic feature. In so far as they indicate a certain degree of instability, fragility, and proneness to decay of the corpuscles, or some altered relations between the plasmic fluid and the viscous globule, such curious alterations in shape may be suggestive of a profound blood-change. But more than this we are not warranted in saying.

Great interest attaches to these corpuscles in respect to their development in the embryo, their subsequent formation, destruction, and renewal; and it cannot be said that our knowledge is yet complete with respect to these matters. Their bearings upon the subject of anæmia are manifestly so important that I must not leave this part of my subject without alluding to them. The primitive blood-cells arise directly from the mesoblastic elements within the developing bloodvessels. These embryonic coloured corpuscles are nucleated, and in early fœtal life the blood is largely composed of such nucleated corpuscles, which gradually disappear with the further development of the body. As soon as the liver and spleen are differentiated the formation of these corpuscles takes place within these organs, although it is not confined to them, the connective tissue cells giving rise to red corpuscles formed out of their protoplasm (Schäfer). There seems no reason why this latter process should not go on in the growing organism after birth, together with the new formation of bloodvessels. In adult life it is generally believed that the coloured corpuscles are developed from the colourless cells of the lymph, the transformation taking place partly in the general circulation, but largely in those organs which are specially devoted to the formation of the corpuscles of the blood—the spleen, lymphatic glands, bone-marrow, and liver. The splenic pulp contains cell elements of different kinds, lymphoid corpuscles of various sizes, red corpuscles, intermediate forms and certain peculiar blood-corpuscle-holding cells, which may represent a stage in the final involution of the red discs, or indicate their evolution from lymphoid cells. As to the lymphatic glands, their *rôle* is evident. The hæmatogenous function of the bone-marrow first described by Neumann twelve years ago is now generally admitted. It was founded on the resemblance of this tissue (especially in young subjects, where it is more vascular, redder, and less fatty than in later life) and its vascular supply to the splenic pulp, containing, as it does, lymphoid cells, cells with coloured nuclei, forming transitional elements between the lymphoid and red corpuscles. The relative abundance of this tissue in youth accords with a like degree of development of cytogenic tissue elsewhere in the body, and affords a contrast in the reparative power, often bloodless at that period as compared with later ages. Hence an explanation for alterations in the corpuscular richness of the blood has been sought in changes in the bone-marrow when the other organs of sanguification have appeared to be unaffected. The liver, which in the embryo undoubtedly is a source of the coloured corpuscles, is by many considered to play a part in blood-formation throughout life, but there does not appear to be yet sufficient proof of this.

One other point of interest concerning the formation of the blood-corpuscles must be mentioned. M. Hayem, who has paid much attention to the subject, and whose observations include not only human blood, but the blood in all classes of vertebrata, has described "hæmatoblasts" of a somewhat different kind from those which are recognised in the marrow or spleen. These are small, rudimentary blood discs furnished by the lymph together with the leucocytes, but so transparent and fragile as to escape observation unless the blood be promptly examined at a freezing temperature or "fixed" by reagents. They are faintly coloured, and in size vary from one-sixth to two-thirds that of the fully formed corpuscles, to which they bear a tolerably constant proportion—viz., one to twenty, being thus considerably in excess of the leucocytes. The existence of small granular masses in the blood has long been noticed, and I have already mentioned the occurrence of smaller forms of red corpuscles, which are regarded by Hayem as intermediary between the very immature hæmatoblast and the completely developed corpuscle; but it is at least singular that these hæmatoblasts, so numerous as they are, should have been so long overlooked by histologists. I may add that their discoverer not only attributes great importance to them in the development of the blood, and regards their presence in undue amount as evidence of incomplete evolution of the blood, as in chlorosis, but asserts that they play a leading part in the formation of fibrin.

Incomplete as our knowledge is as to the precise manner in which the coloured corpuscles are renewed in the blood, it is even less certain as regards the manner of their destruction, and as to their duration as independent, functionally-active elements. For their function is not simply that of carriers of oxygen to the tissues; they also furnish products to secreting glands, and in so doing must be considered to suffer destruction, just as in certain glands—e.g., the mammary,—the cells perish in giving rise to their peculiar product. Indeed, from analogy there would seem to be nothing peculiar in the continued destruction and re-formation of blood-corpuscles; for, although it may be true that a secreting cell often has a certain stability, and after yielding up its product is once more enabled to draw fresh material and convert it to its peculiar secretion, yet there must be a limit to cell life and a renewal of cells in place of those rendered effete by repeated acts of secretion. In the case of the blood there is evidence of the rapidity of renewal of its elements in the increase in corpuscles following ingestion of food, in the diminution during fasting, in the repair of the blood after menstrual loss, or after profuse hæmorrhage, and, indeed, in recovery from anæmia of any kind. M. Hayem, finding the immature corpuscles, or hæmatoblasts, to stand in a constant numerical proportion to the fully formed corpuscles, sees in this evidence of continual change to maintain this ratio, whilst, on the other hand, Quincke, in some recent researches upon artificially induced plethora, has estimated the duration of a red corpuscle to be almost two weeks. There are not, however, sufficient data to remove this interesting point from the region of speculation. We know that the material of the corpuscles is constantly being excreted from the body or deposited in the tissues, and we infer that this implies a destruction of the corpuscle. The actual seat of this destruction is not founded on much surer ground. The spleen has been long regarded as the place where such a regressive change takes place; its richness in iron, its peculiar nucleated cells containing colouring matter, suggest this; and yet the blood of the splenic vein is richer in corpuscles than its artery; so that if the spleen is the seat of their destruction it must also be the seat of their renewal—possibly building up new corpuscles from the relics of the old; besides sending forth also abundance of leucocytes, to undergo further transformation into the coloured elements. However this may be, there is less uncertainty as regards the liver, which seems to be the chief seat of the destruction of red corpuscles; for not only does the blood passing out of this organ contain comparatively fewer corpuscles than that entering it, but its cells are laden with pigment derived from the blood, which they excrete with but little modification in the bile, of which one pigment, the bilirubin, is identical with the iron-free hæmatoidin. Lastly, the urinary pigment must also be derived from the blood; but I do not know whether its precise seat of separation has been determined. [Under certain conditions, probably concerned as much with derangements in the circulation of the kidney as with any actual change in the blood itself, the hæmoglobin will transude into the urine unaltered. Such are the cases of so-called intermittent hæmatinuria, apparently sometimes associated with malarial influences. The appearance of indican, especially abundant in diseases of the alimentary tract, in the urine has relations probably to imperfect changes in assimilation; but its occurrence in anæmia has also been declared, and is suggested to point to some relation with the deficiency of blood in colouring matter.] Lastly, in conditions of artificially induced plethora, and in pernicious anæmia, Quinquad has found a great excess of iron taken up by leucocytes and gland cells in the liver, kidney, and other organs.

Having dwelt at such length upon the red corpuscles, it will not, I hope, be concluded that I wish to ignore the other blood constituents, or the part which their diminution plays in the production of anæmia. But it is because the essence of anæmia lies in the impoverishment of the blood in colouring matter that I have said so little about the other constituents, nor do they need much exposition. The white corpuscles may have other functions than that of giving rise to the coloured corpuscles; they may take part in the renewal of other tissues and cells, but of this we have no concern to-day. In so far as they give rise to the coloured elements, any hindrance to their transformation or arrest of it must deprive the blood of its chief constituent. Dr. Cavafy's interesting research, which points to the leucocytes in leukhæmia being incapable of further transformation, is suggestive of the link between this blood condition and that of pure anæmia.

Then as to the albuminates of the serum and the salts, I have before intimated that they suffer change in anæmic conditions; but I must reiterate my conviction that, as compared with the hæmoglobin, they play but a minor part in the symptoms or effects of anæmia. It is impossible to dissociate them from the condition, for their changes are certainly factors of importance in its etiology; and yet there may be, as in chlorosis, all the evidence of anæmia, with no diminution, but even an excess, of those constituents of the blood.

Scotch Medical Relief Grants.—A deputation from Edinburgh, Glasgow, and other Scotch towns, have had an interview with the Lord Advocate recently at the Home Office on the subject of the grant from the Imperial Exchequer in aid of medical relief for the poor of Scotland, and to urge that the grant should be increased so as to equalise it with the same grants for England and Ireland. The allowance at present made was £10,000 per annum to Scotland, while England received £210,500, and Ireland £71,500, being a half of their actual expenditure; whereas the grant to Scotland was less than one-fourth of its total expenditure. The Lord Advocate promised to arrange with Lord Frederick Cavendish for an interview, by deputation, with the Premier on the subject.

Mr. Alexander Jones, late of Walbrook, bequeathed £200 to the Jews Hospital, Norwood.

THE PATHOGENY AND TREATMENT OF BRONCHOCELE OR GOITRE.[1]

By EDWARD WOAKES, M.D. Lond.

The following observations are mainly based upon the experience of goitrous patients who have attended my out-patient department at the Throat Hospital during the last four or five years. The cases in which the treatment by fluoric acid was adopted and continued to the end are twenty in number. Of these seventeen recovered and three failed to receive benefit from the drug. There are besides preliminary notes of seventeen other patients who attended from one to three times only. These form no part of the series, though they furnish information of an etiological kind, to which allusion will be subsequently made. My notes of about fifteen other cases were destroyed by the carelessness of a porter in charge of the hospital out-patient letters; these, therefore, are not included in the report, as, owing to this misadventure, I have no reliable data to quote from. With regard to the cases themselves, they were not selected for the purposes of treatment, every case of the disease that presented itself being similarly dealt with. This was done with the view of testing the influence, if any, of fluoric acid upon this particular disease. With this object before me, all accessory methods of treatment have been avoided, though it has happened that such accessory treatment has been in one or two instances temporarily added, as when during my absence the patients have been seen by some one unacquainted with my design. Such additions have been speedily eliminated, and were so slight as scarcely to affect the result, except perhaps in Case 10. Speediness of cure has, therefore, been sacrificed to the sole aim of ascertaining first of all whether fluoric acid exercised any remedial influence over the disease.

Before proceeding to further details it may be desirable to discuss the reasons which induced me to select this particular remedy for the purposes in view. As the decision of this point involves principles of fundamental importance, applicable alike to every new attempt to expand the domain of therapeutic resource, I feel the less reluctance in stating briefly in what these principles consist. The first has reference to the pathogeny of bronchocele. The more we consider this subject the more clearly will it appear that the point of departure in the morbid process consists in a paresis of the vaso-motor nerves which mediate the vessel area constituted by the thyroid gland. We shall further localise this paresis, as regards its source, in the sympathetic ganglia from which these vessel nerves issue, and accept as the outcome of such paresis a chronic state of vessel dilatation as regards the area in question. Such a passive augmentation of the blood-supply of the organ expresses itself first in the form of a simple expansion of the normal dimensions of the gland, which then presents a somewhat undefined spongy mass, very compressible, and variable as regards its proportions. Such passive hyperæmias of the thyroid body are not unfrequently seen in the course of certain disorders which complicate that part of the vascular system with which the vessels proper to it are in intimate anatomical relationship. Thus it seems to act as a diverticulum or reservoir for storing away a certain amount of blood, which, if not thus disposed of, would, in the conditions referred to, prove embarrassing to organs of more vital import. It appears to me impossible to recognise any *raison d'être* for the existence of this elastic body at the root of the neck, and in immediate relationship with the great arterial highways to the brain, unless it be viewed in connexion with its vaso-motor associations. The nature of this correlationship will be illustrated by reference to one of them—viz., that by which the vertebral artery, contributing so largely to the intercranial circulation, is located as regards its origin close to the inferior thyroid artery; and, which appears of more importance, that both these trunks derive their vaso-motor nerves from the same sympathetic subcentre, the inferior cervical ganglion. The arrangement is such that a vaso-motor impression proceeding from the ganglion would be likely to influence both these arteries at the same time; that is to say, supposing a dilator wave to be projected upon the vertebral artery, that going to the thyroid gland would participate in it. Under these circumstances, a portion of the blood propelled by the heart into the now dilatable vessels would be immediately drafted off by one of them, and received into a distensible receptacle, the thyroid body, and by so much will the pressure on the vertebral artery be diminished, and the additional amount of blood which would otherwise have been forwarded to the brain will be withheld.

---

[1] A paper read before the Medical Society of London, Feb. 21st, 1881.

It seems therefore highly probable that, owing to this distribution of vaso-motor nerves, the thyroid body is designed to subserve such a mechanical and protective function with regard to the intercranial circulation as I have above indicated, quite irrespective of its physiological purpose in the economy. Obviously such an accretion of blood cannot be indefinitely prolonged without entailing the consequences of hyper-nutrition upon the tissues of the organ in which it takes place. Hence the commonest or rather earliest phase of the disease is a soft and compressible tumour caused by exudative accessions to the unorganised constituents of the gland. It is now called "simple goitre." Later on the connective tissue constituting the stroma of the gland participates in the process, and undergoes changes of a hypertrophic character, causing the tumour to become denser and more resistant on palpation. In this stage it is called "fibrous goitre"; but it is common to see these two forms in different parts of the gland in the same subject, suggesting that the earlier phase is passing on to the later one. Frequently, when the patient is first seen, the disease has become pronouncedly "fibrous."

I need not dwell upon the simple cystic and the fibrocystic aspects of bronchocele; neither need I discuss certain anomalous and rare forms of the disease, which, notwithstanding their extreme interest, are not concerned with my present purpose, which is to show a theory of the inception of the ordinary phases of the disease, and which theory led up to the treatment.

The adoption of a vaso-motor origin of the disease disposes of the views which refer it to some peculiar taint introduced into the system through the agency of drinking-water &c. from the soil—a theory which long held sway. The following considerations oppose themselves to this latter view. An examination of the localities in which my patients lived and acquired their goitrous proclivities shows that out of forty cases in which this point is recorded thirty resided in London or its suburbs, the remainder being contributed by the counties of Hertford, Oxford, Berks, Beds, Bucks, Hants, Essex, and Surrey. In fact, it would be difficult to name any district where the disease is unknown. Locality would seem, therefore, to exercise but a subsidiary share in its pathogenesis. H. Larrey (quoted by Cohen) affirms that infantry stationed in goitrous districts (so considered) acquired the disease, while other branches of the service did not do so—a fact he considers due to the wearing of knapsacks, and the great constriction of the vessels of the neck by the stock and collar consequent thereon, and to which other arms of the service were not subjected. Cohen remarks that the custom of carrying enormous loads on their backs by the Swiss peasantry favours a like result. Bronchocele is often hereditary—a fact which corresponds with observations recorded with regard to other correlated tracts than that of the thyroid gland, in which the tendency to vaso-motor paresis is transmitted by parents to their offspring.

It will be understood that this insistance upon vaso-motor paresis as the starting-point of the disease is not made with any idea of promulgating a new theory, as there has long been a tendency to its acceptance, though in a vague and general way. The remarks already made on this subject aim rather at defining and localising the centre and source of the vessel dilating impetus, and to show how the former is correlated anatomically with the affected area. The so doing removes attention from the nerves, which are the paths of impressions merely, to a more cognisable and potential region—the ganglia of the cervical sympathetic. Its recognition is fraught with important therapeutic meaning.

The phenomena of exophthalmic goitre point distinctly in the same direction—viz., to vaso-motor paresis; but emanating from a wider range of ganglia than in the preceding forms. Portions of the superior cervical ganglion, innervating the internal carotid artery as well as the middle and inferior ganglia, are now implicated in the paretic condition. As these fresh centres are involved new areas of tissue, supplied by vessels innervated from them, become the scenes in which the effects of the consequent dilatation are manifested. These are most evident where tissue is softest, notably the inter-orbital cushion; also in organs whose functions are readily disturbed by such additions to the normal blood-supply, especially, as might be expected, the cerebral centres. On this explanation the nervousness, headache, and mental deterioration of such patients become intelligible; while the functional disturbance of the heart's action, which is one of the most prominent symptoms in exophthalmic goitre, receives a rational interpretation when it is recognised that the cardiac nerves furnished by each of these ganglia to the heart must share, to a greater or less extent, in the depreciation of their centres. Perhaps the most striking commentary on these vaso-motor relations of the thyroid body and the brain is that which is offered by the phenomena of cretinism, witnessed concurrently with goitre in some mountainous districts. For, looked at from this point of view, the monstrously deformed thyroid does not stand to the accompanying idiocy in the relation of cause and effect. The "large heads, wide vacant features, and goggle-eyes" of the cretin point to perverted nutrition in the region of the head during development as much as the fleshy mass which in these subjects represents the thyroid body does in regard of this tissue tract. Both conditions are the outcome of another physiological factor—viz., an inherent defect in the vaso-motor centres regulating the blood-supply of the two regions, and which defect has acquired the maximum of intensity by long ages of breeding in, added to hygienic surroundings of the worst conceivable description.

It is no part of my present purpose to enlarge on this explanation of the association of goitre with cretinism. Its mention will suffice to emphasise the prolific field for the appropriate explanation of many hitherto quite unintelligible phenomena which the recognition of the fact of the correlation of distant regions by their vaso-motor connexions affords to the physiologist.

Compared with other forms of bronchocele, exophthalmic goitre is a rare disease; before dismissing it, it may be desirable to state that in two cases of the kind which had previously undergone a long course of ordinary treatment, and in which I was induced to give hydrobromic acid, a cure was accomplished in what to me appeared an astonishingly brief period. In a third very complicated case of long standing the patient derived only slight benefit. This number of cases is quite insufficient to generalise upon, and I only venture to record the above facts, because in a disease usually so intractable as this a suggestion of proved utility, although insufficiently supported, may be acceptable in some quarters, and also because this drug was given in accordance with a line of argument analogous to that which led to the adoption of fluoric acid in the treatment of ordinary goitre.

It remains to determine what is the condition of the ganglionic subcentres which expresses itself as loss of contractile power in the vessels whose nervi-vasorum are derived from these ganglia. I have already alluded to heredity as a predisposing cause. The nature of this influence I believe to be that, by its means, a certain ganglion, or set of ganglia, are inherently weak—that is, they develop less nerve force, or part with it more readily, or respond more quickly to reflex impressions, which, if strong, they are slow to recover from, than do other ganglia of the same system. Thus the areas over which these inherently weak ganglia exercise vessel control represent, as regards the system at large, the parts of least resistance. There can, I think, be no doubt about this fact that goitre prevails in a mild form amongst all classes to a largely increased degree over that which has hitherto obtained. The same may be said of other diseases of a vaso-motor origin, presided over by the sympathetic centres of the cervical region, amongst which I may mention diphtheria, and laryngeal and nasal affections generally. I am bound to confess it, though I do so with reluctance, as the result of long study of the physiological effects of tobacco, that smoking is largely responsible for this result. Its effects are constantly manifested in the smoker himself in the form of weakened inhibitory force in the centres primarily influenced by the drug; and, secondarily, the offspring of great smokers exhibit a like impairment of the same centres. Probably the most inordinate smokers are young men prior to marriage. Other influences, the outcome of our over-wrought civilisation, doubtless co-operate in the same direction.

Thus much may be said as regards predisposing causes. The immediate cause is in most cases reflex in its nature. In studying the phenomena which attest the existence of correlated vaso-motor tracts throughout the economy, the evidence is very strong that such a correlation exists between the genital organs and others situated in the region of the neck. Though not as yet absolutely demonstrated, there is evidence to show that fibres from the cervical ganglia are in direct continuous communication with the ganglia which preside over the circulation of the genito-urinary organs—thus constituting these regions correlated areas. Stags, Professor Haughton states, which have been injured in one testis, do not grow another fighting horn on the side of the injury, but only a soft velvety projection. Defective innervations and congestions of the larynx, so frequently associated with the growth of this organ at puberty and producing the phenomena of "voice breaking," point in this direction. What is called "functional aphonia" in girls of the same age is of a like kind. Lastly, enlargements of the thyroid gland in youths as well as girls commence very frequently at puberty. I am acquainted with at least one case where the disease in a female commenced synchronously with the development of uterine trouble. Case 4 of the following series illustrates the effects of general shock becoming permanent in the part of least resistance. This girl at the age of eleven years experienced two accidents by which she was greatly prostrated, and immediately thereafter noticed the commencement of thyroid enlargement, which continued till the age of sixteen, when she came under my care, and recovered under the fluoric acid treatment.

The second principle which guided me to select fluoric acid for the treatment of bronchocele is to some extent the outcome of the preceding views on the genesis of the disease. Recognising the existence of those correlated vaso-motor tracts to which reference has been made, it proceeds to acknowledge a physiological relationship between drugs belonging to natural groups, whether in the domain of botany or chemistry, and these vaso-motor areas—that is to say, if a member of a natural order of plants shows a tendency to exert vaso-motor influences upon one of these anatomically defined regions, other plants of the same group will be found to exert similar affinities. And so with chemical groups. Time and prolonged observation can alone affirm the general applicability of this view, or show its incorrectness. Allowing it to be only a scientific projection of the imagination, it comes not the less within the range of principles recognised by the scientific method as justifying the initiation of experiments. It was from this standpoint that I made use of it for my present purpose. Finding that experience had already, though empirically, proved that some members of the group of metalloids, including iodine and bromine, exerted a curative influence upon goitrous disease, the inference that other members of the same group might act similarly, or even act more potently, was strictly within the lines of the therapeutic principle just indicated. The fluorine compounds were, so far as I know, untried. An appeal to them seemed legitimate.

To avoid complication, fluoric acid, or hydrofluoric acid as it is also termed, was selected as the nearest attainable approach to the element fluorine. The unmanageable nature of the acid, and its reputed violent action upon organised tissues, presented obstacles to its use. The unstable strength of the commercial acid was a further hindrance. All these difficulties were overcome mainly through the skill of Mr. Bullock, who readily devoted his energies to provide for the requirements of the case. A pure acid of fairly constant strength is obtained by redistilling the commercial acid; it then contains about 30 per cent. of the gaseous acid. By diluting this acid with 200 per cent. of water, a solution is produced capable of being tolerated by the stomach, and also of being preserved and dispensed in glass vessels. Both preparations should be kept in small quantities, as they undergo deterioration by the lapse of time. The strong redistilled acid must be preserved in gutta-percha bottles, which should be closed with a cork, as the gutta-percha plug usually fitted to such vessels admits air, and spoils the efficacy of the drug. Attention to these details, the importance of which I have learned in a four years' experience, will prevent disappointment in its therapeutic use.

In commencing its administration great caution was exercised. I began with fifteen-minim doses of the half per cent. solution in an ounce of water. As it happened, the first patient for whom it was thus prescribed, having been duly cautioned to discontinue the medicine if inconvenienced by it, presented at her next visit symptoms which somewhat alarmed me. She complained of headache and thirst, had a hot dry skin, a glazed tongue, and abdominal pains. She was at once taken into the hospital as an in-patient, when it became clear she was suffering from typhoid fever, and it transpired that other members of her family were similarly affected. This discovery was a relief, for I confess to entertaining the fear that the new remedy was responsible for the patient's condition. The details of this case will be given in the continuation of this article. It is sufficient to say here that she got well of the fever, and after an interval resumed the acid, and ultimately lost her goitre, which was very firm, and had resisted every other treatment continued over many months.

Although I usually commence with a small dose, half a drachm of the half per cent. solution, it is necessary to increase it gradually, which may be carried out to the extent of two drachms, and this appears to be the limit of toleration for the drug. In smaller doses it occasionally produces slight headache and nausea, for which reasons it may require to be temporarily intermitted.

(To be concluded.)

OBSERVATIONS IN URINARY PATHOLOGY AND THERAPEUTICS.

By C. H. Ralfe, M.D. Cantab., F.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL.

III. CASES OF DIABETES INSIPIDUS CHARACTERISED BY AN EXCESSIVE ELIMINATION OF PHOSPHORIC ACID (THE SO-CALLED PHOSPHATIC DIABETES).

(Concluded from p. 407.)

Case 6. *Polyuria; excessive elimination of phosphoric acid and urea.*—J. G——, aged twenty, was admitted into the Seamen's Hospital on Nov. 13th, 1877, suffering from extreme debility and prostration, and complaining of pain in all his limbs, and especially across the loins. His face was somewhat flushed and the eyes bright, but the temperature was normal; the pulse weak and feeble; chest sounds natural, with the exception of some coarse râles in the large bronchial tubes. Urine clear, acid; no albumen; no sugar. He says the present illness commenced three weeks previous to admission, but he had otherwise always enjoyed good health. During this attack he had lost eighteen pounds in weight. He has a spinal curvature, the seventh and eighth dorsal vertebræ being the bones affected, and he has also a strumous appearance generally.—On Nov. 19th, seven days after admission, the mucous râles in the chest had cleared up, and he was not so prostrate. The pulse was stronger, and the temperature had remained normal during the time he had been in the hospital. Still the patient, in the absence of any definite symptoms, was extremely feeble and weak. Although no sugar had been found in the urine, it was thought advisable to collect the urine for twenty-four hours, and then test for that substance in the whole quantity. —Nov. 20th: The urine collected during the last twenty-four hours measured 4600 cc., and had a specific gravity of 1010, but gave no reaction with Fehling's solution.—Nov. 21st: The quantity of urine collected in twenty-four hours measured 1400 cc., a nearly normal quantity, but the specific gravity had risen to 1029, so that the relationship between the solids excreted on each day was tolerably constant, and exceeded by a third the normal excretion. The urine was collected, measured, and the specific gravity taken subsequently each day during the patient's stay in the hospital; but it will be sufficient here to state that the average quantity passed by the patient each day for a month was 3263 cc., with a specific gravity of 1017. Taking the healthy excretion of an adult to be at the outside 1500 cc., with a specific gravity of 1020, the patient was passing more than twice the normal quantity of urine, and excreting one-third more than the ordinary quantity of urinary solids.

The urea and phosphoric acid were determined quantitatively on several occasions by the house-physician, Dr. Murphy, with the following result :—

Date	Quantity of Urine. Cc.	Sp. gr.	Urea. Grms.	Phosp. Acid. Grms.
Dec. 3rd	4476	1011	67	5·3
,, 4th	4800	1016	116	9·6
,, 5th	4100	1018	103	9·0
,, 7th	3050	1017	61	4·28

On the 13th of December I made a quantitative estimation of the urea and the earthy and alkaline phosphates, with standard solutions distinct from those used by Dr. Murphy, and my results closely corresponded with his—viz., quantity 2700 cc., total urinary solids 108 grms., urea 89 grms. Phosphoric acid in combination with lime and magnesia 1·8 grms.; phosphoric acid in combination with the alkaline oxides 3·7 grms.; total phosphoric acid 5·5 grms. Diet: 4 oz. wine, milk 2 pints, strong beef-tea 1 pint, bread 12 oz. The patient remained in hospital till the 20th December, when he was removed by his friends. His condition was materially improved, and he had regained 15 lb. of his lost weight, but the urinary secretion was not diminished. During his stay in hospital the patient suffered greatly from boils. The patient had no dimness of sight, nor any appearance of cataract. At no time could even minute traces of sugar be discovered in the urine. This may be considered as a typical case of diabetes insipidus, accompanied with increased metamorphosis of tissue. It resembles Willis and Prout's cases of azoturia, and also corresponds to Tessier's fourth group.

The particulars of the six foregoing cases may thus be briefly summarised :—

—	Age.	Approximate weight.	Quantity.	Sp. gr.	Phosp. Acid.	Urea.
Case 1	16	8 st. 7 lb.	2900 cc.	1010	5·2 grms.	51·0 grms.
,, 2	24	9 st.	9500 ,,	1004	6·0 ,,	—
,, 3	25	9 st.	2300 ,,	1015	5·8 ,,	33·5 grms.
,, 4	27	8 st. 7 lb.	1520 ,,	1022	5·2 ,,	41·2 ,,
,, 5	37	12 st. 7 lb.	2020 ,,	1018	7·6 ,,	—
,, 6[1]	20	9 st.	3825 ,,	1016	6·7 ,,	87·2 grms.

In all the increase of phosphoric acid over the normal excretion was considerable. If we except Case 2, they differ from the ordinary hydruric forms of diabetes insipidus, in that the discharge of urine, though considerably more than normal, in no way approached the enormous superflux met with in that form of the disease.[2] On the other hand, the cases in many respects resemble those related by Prout and Willis, and to which those authors gave the title azoturia. As, however, these observers did not estimate the phosphoric acid excreted as well as the urea, it is impossible to say in their cases whether it was increased or not. Dr. Parkes,[3] however, quotes a case of Vogel's, which seems closely to correspond with the instances I have given, and in which the following amounts were passed in two periods of twenty-four hours respectively: Quantity 2800 cc. and 3600 cc.; urea 40·6 grms. and 47 grms.; phosphoric acid 4·1 grms. and 8·3 grms. In this case the urea as well as the phosphoric acid was increased, though the proportionate increase of the latter over the former in the second analysis is prodigious. This is what Dr. Tessier contends for when he gives the distinctive title "phosphatic diabetes" to this form of diuresis accompanied with increased elimination of phosphoric acid; for though urea in some of his cases was in excess, it was not so in all; and this, he says, is the point that distinguishes between azoturia and phosphaturia. Of my cases, in Case 1 and Case 4 the urea was about one-third in excess, whilst the phosphoric acid was more than double the normal excretion. In Case 6 the urea was more than double, and the phosphoric acid treble the normal. In Case 3 the amount of urea was normal, whilst more than double the usual amount of phosphoric acid was excreted.[4] In these cases, therefore, the excess in the elimination of phosphoric acid was proportionately larger than that of the urea.

The question may now be asked, Whether increase of phosphoric acid is not a constant phenomenon in all cases of diuresis, and whether it may not be accounted for by the increased ingestion of food and by the washing out of the tissues by the drain of water through them? Analytical evidence on this point is meagre, but what evidence we have shows that the increase in the quantity of food ingested, or the drain of water through the system, does not necessarily increase the elimination of phosphoric acid. Dickinson[5] and other observers[6] have remarked an increased elimination of phosphoric acid, especially in combination with the earths, in certain cases of diabetes mellitus, but this increase is very far from being universal, as other analyses prove (Parkes).[7] Again, in the cases of diabetes insipidus given by Dickinson, though an increase is noted in some, it is not in all; and in two cases, which I reported in THE LANCET,[8] the phosphoric acid was if anything decreased. For example, in one case in a man weighing 11½ st., the daily average secretion of urine was over 3000 cc., whilst the phosphoric acid estimated on three occasions never exceeded 2·4 grammes. In the second case the patient weighed 8½ st., the urine passed was 2400 cc., and the phosphoric acid was only 1·6 grammes. But if the exaggerated excretion of phosphoric acid is not a constant phenomenon of diabetes insipidus, to what are we to attribute its appearance in the exceptional cases? And here we pass from the consideration of facts to the region of conjecture. There is no question in scientific medicine on which we have fewer facts to generalise from than that concerning the elimination of "phosphates in disease," and consequently there are few subjects which have yielded a richer harvest to the quack. Physiology[9] can only tell us that the element phosphorus is absolutely essential for the growth and nutrition of the tissues, but cannot explain its *rôle*. Whilst, therefore, our information with regard to the physiological action of phosphorus within the body is still so scanty, it is obvious we are not yet in a position to indulge in speculations concerning the part played by it in the production of certain pathological phenomena with which it has been associated. It is satisfactory, however, to know that the attention of scientific workers[10] has been called to this subject, and we may hope that shortly a sufficient number of trustworthy facts may be collected which will enable us to gain a clearer insight into the part played by this important element with respect to the nutritive changes with which it is concerned within the body. Nor is clinical observation in this instance much in advance of our physiological and pathological knowledge. Excessive elimination of phosphoric acid has been noticed in acute inflammation of the membranes of the brain (Bence Jones). In the acute paroxysms of certain forms of mania (Sutherland and Beale), and after injuries to the head (George Harley). But whether in these conditions it is due to increased metamorphosis of the nervous matter or to the irritation of a still hypothetical "coördinating chemical centre," or to the influence of a disturbed condition of the nervous system upon nutrition generally, it is at present impossible to decide. Increased elimination of phosphoric acid, again, Beneke[11] has considered in some cases to be due to excessive formation of acid in the tissues, dissolving out the earthy phosphates; in these cases oxalates and phosphates of lime will both be found in excess in the urine. Similarly in certain cases of dyspepsia associated with excessive formation of lactic acid in the stomach and intestines, more phosphate of lime may be rendered soluble and absorbed into the system, and thus pass out by the urine instead of by the bowel. Marcet[12] has shown from analyses of pulmonary tissue in consumption that a considerable reduction of phosphoric acid and potash takes place both in the insoluble tissue and nutritive material, as compared with healthy lung tissue. And Edlessen[13] has shown that the excretion of phosphoric acid is increased in cases of anæmia, especially pernicious anæmia. The observations of the authors I have quoted are, however, too limited to draw definite conclusions from as yet. All that we are warranted in assuming from them is, that increased excretion of phosphoric acid is met with in those states of the system which we characterise as "nervous," and that it is often met with accompanying or preceding diseases in which disorder of nutrition is usually well marked.[14]

---

[1] Average of five observations.

[2] It may be as well to mention that, though reference is only made to the quantity of urine and the specific gravity on those days when an estimation of phosphoric acid was made, yet observations on this point were frequently made in each individual case, and the relationship was found to be pretty constant.

[3] Op. cit., pp. 10, 367.

[4] Throughout I have assumed the 2·5 grammes represent the normal excretion of an adult weighing from 8 to 9 stone, and 3· grammes for an adult weighing 11 to 12 stone.

With regard to the treatment of the form of disease under consideration, the main indications are rest and an endeavour to promote nutrition generally. To attain this end opium or codeia should be given in full doses, when the patient first comes under observation. As soon, however, as the nervous system is quieted, and the rheumatic and neuralgic pains are less severe, it should be discontinued, lest it interfere with digestion. General tonics, such as iron, quinine, nux vomica, hydrochloric acid, and cod-liver oil should be persevered with. When there is a history of syphilis iodide of potassium should be combined with these remedies. Warm baths, followed by tepid douches, give great relief to the neuralgic pains, and also soothe the nervous system. The soluble phosphates may be administered; but their utility in these cases is questionable. There appears to be no lack of these constituents in the system; the difficulty seems rather to lie in the want of power of the tissues to retain them. The food should be light and nutritious, and milk one of the chief constituents. Alcohol should be avoided; it invariably, even in small quantities, increases the diuresis. The same may be said of coffee. Change to dry, bracing air should be obtained, if possible. The clothing should be warm, and the patient carefully guarded against cold, since in these cases a reduction of bodily temperature is always noted. When, in spite of the pursuance of these therapeutic and hygienic conditions, the diuresis and excretion of phosphoric acid continues, though the general condition of the patient may temporarily improve, there is reason to fear that phthisis will supervene, or that the disease may assume the features of saccharine diabetes.

ELEVEN CASES OF STONE IN THE BLADDER

TREATED BY LITHOTRITY AND RAPID EVACUATION OF THE FRAGMENTS (BIGELOW'S METHOD).

BY WALTER J. COULSON, F.R.C.S. ENG.

CASE 1. — Mr. M——, aged sixty-nine, seen in consultation with Mr. Spencer Watson. Symptoms of bladder irritation began to show themselves during the winter of 1879–80, and became more severe early in May. Retention of urine was a prominent symptom on one occasion, a catheter being required; and hæmaturia was once observed after a rather severe jolting in an omnibus. A calculus was detected on sounding, and on June 22nd Bigelow's operation was performed in presence of Mr. Watson, Mr. Heycock, and Mr. Eastes (who administered ether). The calculus was found to be very loose in texture, and was easily broken up and removed in about ten minutes by means of a fenestrated lithotrite and No. 16 tube. The fragments, composed of oxalate of lime, weighed twenty-nine grains. All symptoms of calculus disappeared in less than twenty-four hours. The urine, however, for some weeks after the operation contained a deposit of pus and amorphous phosphates. This symptom was relieved by warm injections (first plain and afterwards acidulated) into the bladder; the pus disappeared and the phosphates diminished. Four months afterwards the patient was reported to be in excellent health, quite free from pain or discomfort, and able to take repeated railway journeys without ill effects.

CASE 2.—Charles C——, aged sixty, had suffered from symptoms of stone for about twelve years, and had passed small fragments occasionally. The symptoms were much aggravated during the last two years, hæmaturia and severe paroxysms of pain being especially frequent; urine pale, with a thick yellow deposit; alkaline; sp. gr. 1010, slightly albuminous.—Aug. 20th: The patient being under ether, Bigelow's operation was performed, a fenestrated and plain lithotrite being used in succession. Sixty grains of débris were removed in fourteen minutes, through a No. 16 curved tube. Two hours afterwards the patient had a sharp rigor which, however, soon passed off. All the symptoms referable to the calculus speedily subsided, and eight days after the operation the patient was able to walk about in comfort. A fortnight afterwards he reported himself as free from all symptoms of calculus, and much improved in health.

CASE 3.—This case cannot fairly be classified among those treated by Bigelow's method, inasmuch as the completion of the operation was impossible, owing to the cause specified in the notes. The case, however, is a good example of a very important obstacle sometimes met with in lithotrity, and it is therefore inserted in the present series. H. B——, aged sixty-six, had suffered from symptoms of calculus for five or six years, and had passed gravel from time to time. Urine normal in appearance and reaction; no albumen; sp. gr. 1020.—Sept. 3rd: The patient being under ether, I passed a fenestrated lithotrite, and crushed with much difficulty a very hard stone, measuring about an inch and a half in diameter. The fragments were crushed five times, but owing to the rigidity and contracted state of the bladder, it was impossible to continue the manipulations. A small quantity of detritus was removed through a No. 16 tube. In the evening patient had a slight rigor lasting a few minutes; temperature 102°. On the following day patient had somewhat recovered; he had passed several large fragments during the night. Bladder very irritable; urine passed every half-hour. On the 7th patient had another rigor, and the temperature rose to 104°. Urine ammoniacal, and sometimes passed unconsciously. During the next few days there was a little improvement in the local symptoms, but the patient became drowsy at intervals, and diarrhœa set in. On the 17th the temperature was normal, but the drowsiness continued. On the following day the patient was unconscious at intervals, and very little urine was passed. A vapour bath was constructed in the patient's bed, and poultices were constantly applied over the kidneys. Copious perspiration was produced, but the symptoms of uræmia became more and more marked, and the patient died at 10 P.M. on the 19th, sixteen days after the operation. Leave to examine the body could not be obtained.

CASE 4.—C. E——, aged sixty-nine, had suffered from symptoms of calculus for about six months, frequency of micturition and pain after the act being chiefly complained of. Hæmaturia not observed. Urine clear, sp. gr. 1022; acid reaction; slightly albuminous; hyaline casts.—Sept. 3rd: The patient being under ether, a small but very hard stone was crushed with a fenestrated lithotrite. A No. 16 curved tube, a plain lithotrite, and the same tube were introduced in succession, the operation being completed in fifteen minutes, and débris weighing fifty grains being removed. On the following day the condition of the patient was quite satisfactory.—Sept. 5th: A rigor occurred, and the temperature rose to 104°. During the next three days the condition varied; there was some improvement on the 8th, but marked drowsiness was noted on the 9th. This symptom increased, and but little urine was passed. The patient became unconscious during the afternoon of the 10th, and he died at 10 P.M.

Post-mortem examination.—Bladder hypertrophied, but quite free from calculus. The ureters much dilated. The kidneys of normal size, but exhibiting on section numerous disseminated abscesses.

CASE 5.—Mr. M——, aged seventy-four, seen in consultation with Mr. Maurice of Reading. Had suffered from symptoms of bladder irritation for about ten years, and from more decided symptoms of calculus for about four years. On Sept. 4th, the patient being under ether, Bigelow's operation was performed, a fenestrated and plain lithotrite, and No. 16 tube, being used in succession. Eighty grains of débris, composed of oxalate of lime, were removed in thirty minutes. The patient was at once freed from all symptoms of calculus, and his recovery was uninterrupted by any complication. Three months afterwards the patient reported himself as being perfectly free from all trace of his previous symptoms. Mr. Maurice, Mr. Heycock, and Mr. Royds (who administered ether), were present during the operation.

---

[13] Op. cit.

[14] It will be observed that I have not included rickets among the diseases in which an increased elimination of phosphoric acid is noticed. The truth is that the fact of there being an increase is by no means established. Professor Gamgee, in his recent work on Physiological Chemistry, states that no reliable analysis has yet been made to prove it. Whilst Dr. Seeman, who has analysed the urine of sixteen rachitic children, has actually found a diminution, which was most marked when the disease was at its height. Dr. Seeman regards the bone changes in rickets to be due to lime starvation, the salts of that base not being introduced in sufficient quantity into the system, owing to the catarrhal condition of the mucous membrane of the intestines hindering their absorption. ("Zur Pathogenese und Etiologie der Rachitis," von Dr. Seeman, Virchow's *Archiv.*, lxxvii., 1879.)

CASE 6.—Mr. B——, aged fifty-five, seen in consultation with Mr. Maurice of Reading. During the last five years he had frequently passed reddish sand and small particles of gravel, and suffered from bladder irritation. More marked symptoms of calculus showed themselves about five months ago; severe pain in the perineum, aggravated by walking and carriage exercise, being especially complained of.—Oct. 19th: Ether having been administered by Mr. Royds, the stone was crushed with a fenestrated lithotrite, and fragments weighing 116½ grains were removed through a No. 16 tube, the operation being completed in twenty minutes. The relief afforded was immediate and perfect. No bad symptom of any kind appeared, and the patient was quite well, and able to leave his house and walk about with comfort five days after the operation. Messrs. Maurice and Royds of Reading, and Mr. Heycock, were present.

CASE 7.—J. H——, aged fifty-four, had suffered from calculus for some years, and lithotrity had been performed several times. The symptoms had recurred during the last few months. Urine alkaline; sp. gr. 1008; no albumen.—Oct. 22nd: The patient being under ether, the stone was crushed with a fenestrated lithotrite. A No. 16 tube was then introduced, and the operation, which lasted ten minutes, was completed by means of a plain lithotrite and the same tube. Fragments weighing sixty grains were removed. The patient made a rapid recovery, and on the sixth day after the operation he expressed himself as feeling quite well, and free from all his former symptoms.

CASE 8.—Particular interest is attached to this case from the fact that an accident, of a kind hitherto unrecorded, happened to the lithotrite. The instrument in question (one of English manufacture, after Dr. Bigelow's model) was shown at a meeting of the Medical Society (THE LANCET, Nov. 27th, 1880). Mr. F——, aged sixty-eight, a medical man from Northamptonshire, had suffered from symptoms of calculus for about six years.—Nov. 11th: The patient being under ether, and the meatus urethræ having been incised, a large stone, measuring about two inches in diameter, was caught and crushed with a Bigelow's lithotrite. The stone offered much resistance to the instrument, and broke with a loud crack. Three or four fragments had been crushed in succession, when an accident happened to the lithotrite, and it was found that the screw-power no longer acted on the male blade. On examination it appeared that a small screw and two pins, by which the handle of the lithotrite is fastened to the shaft, had given way, so that these two portions of the instrument became separated. It was found impossible to keep them together while the screw-power was applied, and no substitute for the broken screw and pins could be extemporised. By percussion, however, upon the handle, the blades were freed as much as possible from débris, and the instrument was removed. In doing this some amount of injury was inflicted upon the neck of the bladder and urethra, as fragments protruded from between the blades. It was absolutely necessary that the operation should be completed, and this was done by means of a fenestrated instrument, the fragments (composed of lithic acid and weighing when dry 500 grains) being withdrawn through a No. 16 tube. The operation occupied two hours and five minutes, including twenty minutes delay caused by the accident. The patient's son (also a medical man), Mr. Teevan, Mr. Heycock, and Mr. Bailey (who administered ether) were present. No bad symptom followed this prolonged and formidable operation. The urine contained blood for a few hours only, and on the following day there was a slight rigor with vomiting. These symptoms, however, passed off and did not recur. On the eleventh day after the operation the patient was able to retain his urine for three hours at a time, and all symptoms of bladder irritation had disappeared.

CASE 9.—Mr. B——, aged seventy-seven, had suffered from symptoms of irritation of the bladder for rather more than two years, and had noticed blood in his urine during the last year. These two symptoms are now frequent, especially after exercise. He passed a small concretion about a fortnight ago. On Nov. 23rd, ether having been administered by Mr. Knott, and the meatus urethræ incised, the stone was crushed with a fenestrated lithotrite. A No. 16 tube was then introduced, and débris weighing 198 grains, and consisting of fragments and small calculi, was removed. The time occupied was thirty-five minutes. No bad symptoms followed the operation. On the 24th and 25th the patient's condition was quite satisfactory. On the 26th he became feverish, and complained of pain along the urethra, and the urine was high-coloured and offensive. The introduction of a catheter and the removal of four ounces of residual urine gave great relief. The feverish symptoms subsided, and on the 28th the patient was able to leave his bed for about three hours. By the following day all symptoms of irritation of the bladder had entirely subsided.

CASE 10.—A. P——, aged thirty-two, stated that he had seen blood in his urine from time to time during the last two years, but that pain in the bladder and penis (especially after micturition) had troubled him for twelve months only. Micturition now very frequent, the flow of urine sometimes stopping suddenly. Urine: specific gravity 1015; alkaline reaction; slightly albuminous; hyaline casts.—Nov. 24th: The patient being under the influence of ether, and the meatus urethræ having been incised, a fenestrated lithotrite was introduced and attempts made to crush the stone, which was found to measure three inches and a quarter in diameter. The calculus, however, resisted all the force that could be applied to it, and Bigelow's lithotrite was then substituted. After several attempts the stone gave way, and some large fragments were then caught and crushed. The débris was removed through a curved tube. The stone was again seized with a strong fenestrated instrument, which, however, gave way when the screw-power was forcibly applied, the handle separating from the shaft. This being withdrawn, several instruments were used in succession, and after repeated crushings and removals of débris the operation was completed; it occupied three hours and a quarter. The weight of the débris removed was 1890 grs. At 9 P.M. the patient's condition was satisfactory; no sickness or rigor, and but litle pain. On the following day there was some amount of febrile reaction, but this gradually passed off. On the 27th the temperature was 99·4° and the pulse 96. No rigor had occurred, and there was no pain over the bladder. On the 30th the patient complained of pain at the end of the penis, and on the following day the bladder was examined with a lithotrite, but no fragment could be detected. On Dec. 2nd the patient reported himself as feeling comfortable, and able to retain his urine for two hours.

CASE 11.—J. W——, aged fifty-six, had suffered from symptoms of irritation of the bladder for several years, and frequently noticed hæmaturia. The symptoms had been more marked during the last twelve months. Urine: sp. gr. 1016; alkaline; no albumen. The patient on coming under observation (Nov. 22nd) complained of thirst and feverishness. Evening temperature 103·4°.—Nov. 24th: Ether having been administered, and the meatus urethræ incised, a calculus about an inch in diameter was crushed with a fenestrated lithotrite. A No. 16 curved tube was then introduced, and the fragments removed. The operation was completed by means of a plain lithotrite and the same tube. It occupied twenty minutes, and débris weighing 150 grains was removed. In the evening after the operation the temperature was 98·4°; the patient complained of a little pain over the bladder. This, however, subsided on the following day, when the condition was in all respects satisfactory. On the 28th the patient was allowed to leave his bed, and on the 30th to take a short walk. On Dec. 3rd, nine days after the operation, the patient reported himself as quite well, free from all symptoms of calculus, and able to retain his urine for several hours.

Remarks.—There are several points of interest connected with these cases. The calculus in the first case was of a somewhat rare kind, for owing to the absence of any binding material the particles of oxalate of lime were very loosely attached to each other. Mr. Poland has reported the removal by lithotomy of a similar calculus ("Holmes's System of Surgery," vol. iv. p. 1024). With regard to Case 3, it is not to be taken as an example of Bigelow's method, for the success of which the removal of the calculus at one operation is a necessary condition. In this case, owing to the state of the bladder, that condition could not be fulfilled. Symptoms due to suppression of urine rapidly supervened, and although the patient survived more than a fortnight, his state was such that no further operations were deemed expedient. The fourth patient was known to be suffering from chronic nephritis, but as the stone was small, and the operation speedily completed, there was every reason to hope that the renal complication would not become seriously aggravated. For forty-eight hours all went on well, but symptoms of uræmia supervened, and the condition soon became hopeless. The nine successful cases illustrate in various ways the advantages of Dr. Bigelow's method, the relief afforded in the majority of these instances being rapid and complete. Cases 1, 2, 5, 6, 7, 9, and 11 are particularly noticeable in this latter respect. In Cases 8 and 10 the accidents which occurred to the lithotrites complicated the proceedings and caused some delay in completing the operations. In the latter of these cases the stone was a very large one (4 oz. 140 grs.), indeed it would appear to be the largest hitherto removed by lithotrity. In a case mentioned in Dr. Bigelow's work the fragments weighed 4 oz. 52 grains, and the removal required three sittings occupying eight hours and a quarter. In the present case, in spite of the delays caused by the giving way of the instrument, the operation was completed in three hours and a quarter. The successful result in both of these cases justifies the belief that calculi four ounces in weight may be dealt with by Bigelow's operation provided that the condition of the bladder is favourable to lithotrity, and that instruments can be constructed capable of bearing the enormous strain involved in crushing. On examining Bigelow's lithotrite one is struck by the enormous power of the blades as contrasted with the imperfect manner in which the handle is connected with the shaft and the consequent inadequate resistance to the force applied by the screw. This imperfection, however, can doubtless be remedied. Care has been taken to point it out to the makers of the instrument. The remaining mechanical portions of Bigelow's instrument leave little to be desired. The ball by which the screw-power is applied, and the revolving cylinder-handle for opening and closing the lock, are decided improvements upon the wheel and button of former instruments when large stones have to be dealt with, while the power of the blades has been sufficiently tested in the cases just referred to. With regard to the time occupied in the operation, Dr. Keyes states that he removed from nineteen patients 4241 grains of stone in 938 minutes, or on an average 4½ grains of stone for each minute of work. The total weight of débris removed in the ten cases of this series was 3133 grains, the time occupied in the operations being 454 minutes. This gives an average of nearly seven grains per minute of work. With instruments improved as suggested it is probable that this average might be much increased.

Harley-street, W.

AN OUTBREAK OF TRICHINOSIS (?) FROM EATING THE FLESH OF A WILD BOAR.

By JOHN WORTABET, M.D.,
PHYSICIAN TO ST. JOHN'S HOSPITAL, BEYROUT.

The village of Khiam, where this disease has recently broken out, lies not far from the principal sources of the Jordan, which, losing themselves in the plains of El-Huleh, form a large marsh. From the thick jungles of papyrus which occupy that marsh a large wild boar was shot and brought to Khiam on the 25th of November. This was a great treat to the poor villagers, who can rarely afford to indulge in butcher's-meat, and many of them ate the flesh, partly raw and partly half-cooked. The meat was observed at that time to be perfectly fresh and good, and no one noticed that it was in any way diseased; but during the course of the second week all the persons who had eaten became ill, and if any escaped at that date they suffered a short time later. Of those who had abstained not one fell ill. The nature and symptoms of the disease were the same in all the victims; but those who ate the flesh raw suffered most severely, and the children generally suffered less than adults. The head of the boar was sent as a present to a family in Hasbeya, some miles north of Khiam, who boiled it very thoroughly before eating it, and though a good number joined in the repast no one of them suffered in the least.

These facts I verified by visiting the place of the disaster, which is a two days' journey from Beyrout, and where I spent Jan. 1st and 2nd in studying on the spot all the circumstances of the case. I found 257 persons more or less ill—viz., men, 121; women, 101; children, 35. Five others—three men and two women—had died before my arrival. I carefully examined the symptoms and the course of the disease in a large number of those cases, about which there was a remarkable and almost wearisome identity. The main points were as follows:—From ten to twenty days after eating of the meat the face and extremities became œdematous, the swelling extending over the whole body. This was accompanied by severe pain in all the muscles, with more or less fever. These phenomena did not generally continue more than two or three weeks, and were followed by a slow convalescence with much weakness and lingering muscular pains, and occasionally by slight relapses. I shall now proceed to state the matter in a somewhat more detailed manner.

As I entered the village I was at once surrounded by some twenty men, women, and children, all of whom had been among the victims. Their faces were still puffy and pale, and they looked very weak, but convalescent. They all had one story to tell: "We ate of the flesh, but did not feel unwell till some days after, when we had much pain all over the body, swelling, and fever. We are now much better, but very weak, and not free from pain yet." In examining carefully a few of the cases I found nothing more than they had stated. The tongue was clean, the appetite good, and the functions of the alimentary canal normal. In almost every case, however, there was a peculiar appearance of the floor of the mouth, the inferior surface of the tongue, and the gums. Situated on the mucous membrane there were small white conical projections, a few of which I clipped and subsequently examined with the microscope, but with negative results as to the existence of any parasite within them. The gum often presented the appearance of congested patches, while at its border, where it dips into the alveoli, it was sometimes red, and bled easily on pressure.

The period of incubation does not seem to have ever been under ten days, though it was prolonged in some cases to twenty. In one individual, who had eaten the meat fairly cooked, the disease did not appear before the end of the fourth week, and then it was so slight that he was not laid up by it. I asked particularly whether they, or any of them, felt unwell during that time, and they were all unanimous in saying that up to the date of the actual invasion of the disease they felt as well as usual. I heard, however, of one man who had vomiting and diarrhœa soon after eating, probably the effect of an overloaded stomach, and that he was one of those who had suffered the least. The instances in which the disease appeared later than the second week were very few.

The order of the symptoms, after the disease was fully declared, appears to have been, as far as I could find out, a swelling of the face and extremities, accompanied or soon followed by severe pain in all the muscles of the body, and more or less fever, with headache, thirst, perspiration, and much itching of the skin. These symptoms continued about two weeks, and it was during this period that five persons died, apparently from the effects of the fever. The majority of the sick became then slowly convalescent and left their beds. Having learned this much from these people I next visited the sick who were still confined to their beds. This number could not have been far from 100, but most of them were evidently beginning to recover, and with the exception of an œdematous state of the face and extremities, and lingering pains in the muscles, with, perhaps, a slight febrile reaction towards the evening, there was nothing particular to observe. The severer cases, which were not more than five or six, presented still the typical features of the disease. The fever was of an asthenic form, in one case with a dry typhoid-looking tongue, and appeared to be of a secondary character in the chain of morbid phenomena, and probably produced by a general irritation of the whole system. The pain, which seemed to invade all the voluntary muscles, was very severe, but appeared most in the muscles of the extremities and at the different points of their attachments to the bones. Both flexion and extension were very painful, and the patient lay generally on his back, with his limbs in a state of semi-flexion. In one instance I found the calf of the leg hard and very tender on pressure. Every movement gave pain, and the muscles of mastication, swallowing, and breathing seemed to be all equally implicated. The voice was somewhat husky, and there was pain in the region of the larynx. At one time during the march of the disease they complained of a swelling in the tongue, and some had suffered from conjunctivitis, of which I saw two instances. The bowels seemed to have been regular throughout, and I was struck by the normal state of the alimentary canal and digestive functions where there was so much suffering and constitutional disturbance. Some of those who were still sick in bed had been better, but had relapses, which they attributed to imprudence on leaving their room too soon.

I asked the older men of the village whether they had ever observed such a disease among them from eating the flesh of wild boars, which are frequently hunted during winter from the neighbouring jungles. They said they never had anything of the kind, but that some ten years ago there was a similar outbreak from the same cause in the village of Kiniat, a few miles to the east, and when about twenty persons lost their lives. I had a confirmation of this from other quarters, and I have no doubt that it was true. I was told, also, that the wild boar lives chiefly on the roots of the canes which are so abundant in the marshes, and as he burrows the ground with his snout he snaps up small animals, such as worms, snakes, and wild rats—the latter of which are said, I believe, to be sometimes infested with the trichina spiralis.

Was this outbreak, then, in Khiam one of trichinosis? I am sorry to say that the one incontestable proof—the microscopic demonstration of the parasite—is up to this date still wanting. No case of death took place while I was there, and to open a grave would have been perhaps impossible. All traces of the boar had disappeared. One brave man offered his arm for examination, but I did not like to inflict pain and injury on the poor fellow who was still suffering severely from the disease. I heard of a cat which had eaten of the meat and died, but it could not be found. I heard of another in regard to which the statements were very contradictory as to whether it had eaten or not. It appeared well and quite lively. On killing it, however, and examining different pieces of muscle with the microscope, I found them quite healthy and free from the parasite.

I still hope to obtain a piece of muscle for examination from one of the bodies of those who died from the disease, and to communicate the result. In the meantime it is quite rational to believe, judging from the history of the outbreak, and from the symptoms of the disease, that we had here probably another instance of a trichinatous infection on a larger scale than has hitherto been recorded. If it were not that, what else could it have been?

Subsequently I received a letter from the pastor of the Protestant community in that village, in which he says: "No more deaths after you left us. The patients are gradually improving, and those who are still in bed are few; but some are still swollen, and complain of pain in the hands and feet. They are all very weak and incapable of work, while a few have intermittent fevers, for which they are taking quinine."

P.S.—Since writing the above one of the victims mentioned—a somewhat aged woman—whom I had seen quite ill when I was there, has died, and I have succeeded in obtaining from the body a piece of muscle (biceps brachialis), which reveals under the microscope a good number of trichinæ, and sets at rest any question as to the nature of the disease. The parasite lies coiled across the primitive fibres, and apparently within the sarcolemma of the fasciculi, and appears to be free—not enclosed in a cyst. The stage of calcification of the capsule may not have been reached, or the sac may have been too transparent to allow of detection. The trichinæ may be obtained free of the muscular tissue by a moderate pressure of the covering glass, but they are apt to get thus uncoiled, and to lose their characteristic spiral form. I have had a few specimens mounted, and will try to send a piece of the muscle itself by this mail. To the naked eye the tissue has a perfectly healthy appearance. I have also received another letter from the village, which states that they were having a good number of relapses, and mentions particularly a return of the swelling, of muscular pain, chiefly at the bend of the elbows and knees, and of much itching over the whole body. The patients complain of a sense of sudden failing if they cannot get at food as soon as there is a craving for it. Many are still in bed, and those who are able to be out feel very weak, and continue to feel pain. I fear there will be some more fatal cases.

Beyrout.

[NOTE.—We received from Dr. Wortabet a specimen of muscle referred to in the postscript, and on submitting it to microscopical examination, we found it to contain a large number of non-encysted embryo nematoids. An examination of the isolated worms showed them to possess the general shape, with terminal anus, met with in the embryos of trichinæ spiralis. They were too immature to admit of any details of organisation being made out. They were found to be $\frac{1}{30}''$ long by $\frac{1}{900}''$ broad. For the most part they were situated in the midst of small connective tissue overgrowths between the muscular fibres, and the fact that they were non-encysted is in accordance with the other fact that they had not yet attained the usual size of encysted trichinæ.—ED. L.]

ON THE

ANTIPYRETIC TREATMENT OF TYPHOID FEVER BY MEANS OF SODIUM SALICYLATE.

By HENRY TOMKINS, M.D.,
MEDICAL OFFICER TO THE MONSALL FEVER HOSPITAL, MANCHESTER.

(Concluded from page 410.)

OF the total number of patients treated, 14 (6 male and 8 female) proved fatal, and at first sight this may not appear to present a very favourable case for the employment of the salicylate. Forty-six cases show a mortality of 14, or something like 30 per cent., but the fallacy of mere figures is proverbial, and before hastily coming to an adverse conclusion several qualifying conditions are to be taken into account. Firstly, the whole of these are selected cases—selected on account of their marked severity,—those cases in which the ordinary resources of medicine and therapeutics offered at best but a faint hope of success; they were, in fact, chiefly that 15 or 20 per cent. which up to the present all our efforts have been unavailing to save. Again, in addition to the well known fact that the cases brought for treatment to hospital are, as a rule, more severe than those treated elsewhere, there is this to be borne in mind, that during the time over which these extend the patients admitted here include a large proportion of pauper cases, the mortality among whom is always higher than in those of a better social status, as is well shown by the statistics of the London Fever Hospital, where, after the exclusion of pauper cases, the death-rate at once was considerably lowered. But further, on examining these 46 cases, it is found that 5 of them were almost hopeless on admission, and in 4 death was the result of intestinal hæmorrhage and lung complication.

A point deserving of some attention is that in a large proportion of the fatal cases the temperature resisted the antipyretic action of the soda, even when pushed to extreme doses; and from my experience I would submit that whenever the poison appears to have got so firm a hold of the system that the salicylate in full doses, after twelve' hours administration, has failed sensibly to reduce the temperature, the prognosis is most unfavourable, and its further use is not to be persisted in.

Would space permit, more complete details of the above would furnish abundant proof of the power the salicylate has in rapidly reducing the pyrexia, and influencing beneficially the course of the disease, but one case only must here suffice.

Sarah H——, a fairly well-nourished child, aged seven, admitted April 9th, 1879, with indistinct history of vomiting, headache, and purging; ailing about a week. Complains now only of headache and feeling tired. Face flushed, much hebetude, intellect confused, rambling when left alone. Abdomen distended; pain and gurgling in iliac fossa. Area of splenic dulness enlarged. Temperature on evening of admission 103° F.; pulse 136.—April 10th: Next morning the temperature had fallen half a degree; pulse 128; respiration 30. Lungs normal; urine free from albumen; purged twice in the night, "pea-soup" stools. Tongue covered with thick moist fur; very delirious in night; quieter now.—11th: But little change; more lethargic; purging increased; little subsultus tendinum. Morning temperature 102°; evening 102·8°.—12th: All symptoms increased in severity; one or two spots visible on abdomen; very prostrate and delirious, and much purged; temperature at eight A.M. 103·8°. From ten A.M. until eight P.M. five grains of salicylate were given every two hours with the following result:—At ten A.M. the temperature was 104°; at twelve, 104·2°; at two P.M. 104·4°; at four 104°; at six 103·6°; at eight 102·2°; at eleven 101·4°. After eight P.M. the same quantity every three hours. At two A.M. the temperature was 99°; at five 99°; at eight 99·4°. On the 13th at eleven A.M. 99°; at two P.M. 98·6°; at five 99·6°; at eight 100·6°; at eleven 98·4°. After six doses had been given the restlessness was somewhat increased, patient was very deaf, and urine contained a small quantity of albumen, but after increasing the interval between the doses from two to three hours these effects were abated, and she passed a fairly quiet night. The same dose was continued every three hours until eight P.M. on the 17th, when it was discontinued, the patient being quite calm and quiet, free from all delirium. The purging had diminished, the stools being semi-solid. She took milk and beef-tea willingly, and asked for more solid food. From this time the temperature never rose above 100°, and only reached this twice—i. e., on the evenings of the 23rd and 24th. She appeared fairly convalescent on the 20th, and was discharged on May 3rd thoroughly recovered.

In this case, as could be shown in others, it is scarcely to be denied that the action of the soda was most prompt in reducing the temperature, and in so doing modifying and checking the course of the disease. And in the use of any remedy for any ailment one's own individual experience as to the direct effect obtained, together with the ultimate result, is not to be set aside in favour of mere statistics, notwithstanding the importance of these when properly estimated.

To sum up as far as my own individual experience goes, I would say that in all those cases where the temperature *plus* the symptoms appear to demand the speedy reduction of the former, we have in sodium salicylate a means of reducing it as certain in its effects and far more easy of administration than the immense labour involved in the repeated application of the cold bath. Especially is it applicable to that large number of cases treated in ordinary private practice, if but a moderate and necessary attention be given to the effects and action of the drug. In all cases where there is a continued temperature in the axilla above 102°, there may be given to an adult bi-hourly doses of fifteen to twenty grains for the first twelve hours, half that quantity the next twelve hours, and continue this for two or three days, regulating the amount simply by rising or falling of the temperature; if it be kept below 100° not giving it oftener than every three or four hours. Where possible it is satisfactory to register it every two or three hours, but night and morning will suffice to show what effect the soda is having. Where the heart's action is already weakened it is of importance to administer alcohol in fair quantity with each dose. Perhaps the two conditions, where it is chiefly contra-indicated, are: where pre-existing renal disease is present, and in those cases where we have to deal with much lung complication. The use of alcohol in conjunction with the salicylate is frequently of marked benefit, for without doubt when pushed to extreme doses it has a depressing effect upon the heart's action; but certainly not more so than is often seen after the cold bath, which not unfrequently, in severe cases, is followed by a condition bordering on collapse. If well diluted it is but seldom that nausea, vomiting, or derangement of the stomach is produced, comparing favourably with quinine in this respect. The diarrhœa was usually lessened after its exhibition, though Dr. Greenhow, in some cases of rheumatism treated by him, thought that diarrhœa was induced by its use (*Brit. Med. Journal*, May 29th, 1880); and as Dr. Rutherford has shown it to be one of the most powerful biliary stimulants in the dog we might have expected to meet with increased purging from its use, but such is not borne out by the above cases. As to the excessive anæmia noticed by Dr. Greenhow as following its administration I have never seen it, although given in larger doses than he appears to have used. The only anæmic case was the 45th of the series, and this patient was apparently in an anæmic condition when attacked by the disease, and for some weeks after convalescence from the typhoid was the subject of pelvic cellulitis.

I hope hereafter to give the results of further use of this remedy, and trust that in the meantime others may be induced to make trial of it, and to record their experience of this, our most powerful antipyretic.

Manchester.

ON THE CONTROL OF DIARRHŒA IN ENTERIC FEVER.

By JAMES W. ALLAN, M.B.,
SUPERINTENDENT AND PHYSICIAN, CITY OF GLASGOW FEVER HOSPITAL, BELVIDERE.

It is, perhaps, better not to attempt to check the diarrhœa of enteric fever so long as it is mild—that is to say, as long as the motions do not exceed three or four in the twenty-four hours. But when the stools are very loose and copious, as well as frequent, it becomes a very desirable thing to control, if not to stop, the diarrhœa. Severe purging rapidly exhausts a patient. In the case of children the following measures may be tried:—(1) Boiling the milk which constitutes patient's diet; (2) boiling cinnamon in the milk, and straining it; (3) adding lime-water to the milk in varying proportions, say from one in four to half-and-half.

The above simple remedies are well worthy of trial. They have the great advantage, in the case of children, of not being "bad to take," and further, while the patient is taking the medicine, he is taking his diet (i. e., milk) at the same time.

In the case of adults the means just mentioned should first of all have a trial. If they fail we may then try (1) that excellent pill—lead pill with opium,—say one every three or four hours till the diarrhœa is restrained. This pill is very valuable in the treatment of purging, and it has the additional advantage of tending to relieve pain and check flatulent distension of the intestines. Should the purging continue, and especially if the desire to go to stool be urgent and persistent, we should at once resort (2) to the use of the starch and laudanum injection—say ten, fifteen, or twenty drops of laudanum in two tablespoonfuls of thick starch injected into the rectum. This is a capital remedy; it checks the diarrhœa, allays the irritation, and probably at the same time disposes the patient to sleep. It is perhaps unnecessary to add that no beef-tea should be given while there is diarrhœa.

GUY'S HOSPITAL.

OLD-STANDING STRICTURE OF THE URETHRA; CYSTITIS; FOREIGN BODY IN BLADDER; EXTERNAL URETHROTOMY; SUPPURATIVE PERITONITIS; PERFORATION OF BLADDER; BEDSORE; DEATH.

(Under the care of Mr. Bryant.)

For the notes of the following case we are indebted to Mr. Adeney.

Robert W——, aged thirty-nine, was admitted into Job ward on Dec. 8th, 1879. When eighteen years old he had gonorrhœa for three weeks. No injections were used. Three years after the gonorrhœa he noticed the stream began to grow smaller. Eleven years later internal urethrotomy was performed at the London Hospital. Relief only lasted a week, and then perineal abscess followed, leaving a urinary fistula. During the last four years he had passed a catheter himself. A few weeks before admission he began to pass catgut bougies, and on the 6th he passed one, but the next morning the stop had come off and the bougie had disappeared. A medical man whom he consulted passed a No. 2 silver catheter, and the next morning he passed it again with great difficulty, and obtained about half a pint of urine.

On admission he suffered from acute attacks of violent straining and intense pain round the root of the penis. The bladder reached halfway to the umbilicus, but was not tense. A No. 2 elastic catheter was passed, and only a few drops of bloody fluid came away. On the 9th, under chloroform, an attempt was to be made to withdraw the catgut by a lithotrite; but, although the meatus was slit, the instrument would not pass. A bougie was next passed, and the urethra was found to be as rough as a rasp. Efforts were made to dilate the urethra, but failed. The patient was then put into the lithotomy position and a Syme's shoulder-staff was passed into the urethra; but, as it could not be determined whether the staff had entered the bladder, a careful incision was made in the middle line. The staff could not be felt at the bottom of the wound, so the incision was extended into the dilated urethra. A finger was introduced and the coiled catgut was removed. A No. 9 catheter was passed through the wound into the bladder, and about a pint of very offensive urine came away. A small sponge was placed in the wound and a large sponge threaded on to the catheter, and the whole bandaged up. After the dressing was completed, considerable hæmorrhage being apparent, the dressing was removed, and an artery, apparently the artery to the bulb, was found to be the cause of the bleeding. The patient had constant severe pains for days, for which subcutaneous injection of morphia was given each night. On the 18th, the buttocks were œdematous, and the skin was rubbed off with only very slight irritation. The patient was very restless, and complained that his feet were cold, but they were not apparently so. He swallowed milk and medicine with difficulty. The edges of the wound were sloughing, and pus could be squeezed out from beneath the dartos of the scrotum. In the afternoon an incision was made into the left buttock, and a considerable quantity of pus escaped. On the 22nd a considerable discharge had taken place from opening on buttock; a quantity of sloughing fascia was removed. On the 24th the vitality of the skin was very slight. There was superficial gangrene above the right iliac crest, and there was fluctuation just above this point. Redness over the left great trochanter. The tongue was very dry and red, with brown fur down the middle. On the 29th a slough was removed from above the right iliac crest. There was dry gangrene over the left trochanter. Next day the patient was getting weaker; he had no control over the sphincter ani, and liquid fæces constantly passed. Where the slough had been removed from above the right iliac crest was now a deep ulcer. The posterior border of the external oblique was seen in front. No pus discharged. There was a large amount of sloughing tissue about the abscess in the buttock. There was great pain on pressing on the spine of the sacrum and lower lumbar vertebræ.

The patient died on Jan. 3rd, 1880.

Temperature.—Dec. 10th: Morning, 99·3° F.; evening, 100·6°, 11th: Morning, 100°; evening, 100·4°. 12th: Morning, 100·2°; evening, 102.° 13th: Morning, 101·1°; evening, 96·6°. 14th: Morning, 98·6°; evening, 99°. 15th: 98°. 16th: 98°. 17th: Morning, 99·2°; evening, 98·5°. 18th: 96·8°; evening, 99·2°. 19th: Morning, 99·2°; evening, 98°. 20th: Morning, 98·4°; evening, 99·3°. 21st: 99·4°. 22nd: 98·2°. 23rd: 98°. 24th: 97·4. 25th: Morning, 100·1°; evening, 99°. 26th: 98·7°. 27th: 98·7°. 28th: 98·8°. 29th: Morning, 99·6°; evening, 99·4°. 30th: Morning, 98·4; evening, 99·3°.

Necropsy.—There was a dry slough over the left trochanter and superior iliac spine. A superficial slough on sacrum, and a large intermuscular abscess all over the left innominata bone. This could not be traced to any source, but it probably came from the perineum. Its tract was very small, and had previously closed. There was recent lymph on the pleura of the right upper lobe of the lung, as well as near the base, and over a patch of pneumonia. There were areas of pneumonia in both lungs, red and granular. The bronchi were dilated, and the smaller bronchial tubes were full of thick pus, constituting a formidable amount of papillary bronchitis. The larynx and the heart were both healthy. The small intestines gave a slight reaction with iodine. The liver weighed 48 oz.; slightly lardaceous throughout. The spleen weighed 4½ oz.; not lardaceous. The kidneys weighed 10 oz. Capsules adherent on both sides, and the surfaces minutely granular. The capsules on the right side were much thickened at one spot, as if there had been at some former time a perinephritis. The corresponding part of the cortex was not depressed. The right kidney contained one rather conical area of suppuration extending from the medulla to the cortex. The pelvis on this side was dilated and ragged, ecchymosed all over, and studded with irregular shields of lymph, and the apices of the pyramids were all sloughing; it contained offensive ammoniacal urine. On the other side there was some dilatation, but not much in the way of inflammation. The pelvis was pale, and at most had a few ecchymoses upon it. The right ureter was intensely inflamed all down to the bladder, dark and port-wine coloured. The left was healthy, except that its mucous membrane was slightly injected near its orifice in the bladder. Neither tube was dilated. The bladder was thick, but it was closely contracted. Its mucous membrane was much injected, and at the hinder part of the base in the median line, and at what was now the fundus, but was probably not so in the fully distended bladder, there was a sloughing hole, surrounded by swollen rugæ, covered with phosphates, &c. This hole led straight into the peritoneum, and was filled with a partially detached slough. This led into a localised abscess in the perineum. The urethra was very contracted from the meatus to the posterior part, so that it could not admit a No. 2 sized probe. It was slit up with difficulty. The prostatic part was dilated, and covered by a shreddy membrane and slough, and phosphates. One testicle was converted into a fibrous mass, with adherent tunica vaginalis, and a chalky mass in the centre. The other was much wasted, if not fibrous. The coats of the ileum were firmly adherent round the fundus of the bladder, forming a cavity two or three inches in diameter, lined by large granulations, and containing pus and fæcal matter. The latter proceeded from two or three apertures in the ileum, which had formed by extension of ulceration of the wall of the abscess. There was a quantity of pus in the peritoneum and various places, all shut off and localised; it was also thick and creamy; in Douglas's pouch there was a large quantity, in the left iliac region in front of the kidney; there was also much behind the right lobe of the liver. The omentum was firmly adherent over all. The suppuration must have been of some date longer than a month. On the other hand, it is difficult to suppose that the patient was going about with the bladder perforated, and the peritoneum suppurating. If it was after his admission, then was the early lardaceous disease of more than twenty-six days' date, or was it in part due to some old cystitis?

STRATFORD-ON-AVON INFIRMARY.

SMASHED ELBOW; AMPUTATION; ANTISEPTIC ABSORBENT PADS; RAPID HEALING.

(Under the care of Mr. LUPTON.)

GEO. G——, aged eighteen, was brought to the infirmary on June 17th, 1880, by Mr. Millican of Kineton. The patient worked at a clay-puddling mill, and getting his arm caught by the machinery, it was drawn in and "puddled" with the clay. The joint was disintegrated, and the brachialis anticus and triceps were stripped up from the humerus; the brachial artery was severed, and the skin was much torn and lacerated. Amputation in the middle third of the upper arm was immediately performed by Mr. Lupton by skin flaps and circular division of muscles. The vessels were tied with carbolised catgut, prepared by Krohne and Sesemann, and the ends were cut short. The stump was cleansed with carbolic lotion (1 in 40), and covered with the "antiseptic absorbent pads," as recommended by Mr. Sampson Gamgee, and prepared by Southall Brothers and Barclay. The wound was first dressed on the 20th under carbolic spray, and was only exposed to an antiseptic atmosphere at each subsequent dressing. Gamgee's pads were used next the wound, and covered with a large layer of cotton-wadding.

The progress of the case was all that could be desired. At the second dressing, June 22nd, the discharge was only just sufficient to soak through one pad. At no subsequent dressing was a pad soaked fairly through. Healing proceeded very rapidly, and on the seventeenth day after the operation the wound was quite sound, and the patient sitting up to dinner in the ward. Nothing more was seen of the ligatures.

SMASHED HAND; ATTEMPTED "CONSERVATIVE SURGERY"; GANGRENE OF FLAPS, WITH INFILTRATION ABOUT WRIST; RE-AMPUTATION IN FOREARM.

(Under the care of Mr. Lupton.)

William C——, aged forty-seven, an army pensioner, twenty-one years' service, including the Mutiny and much arduous service, was admitted on November 8th, 1880, suffering from a smash, caused by a trolly-wheel passing over his hand. The thumb and second, third, and fourth fingers were completely smashed, and their integuments destroyed. The index finger had escaped. There seemed a chance of saving this; accordingly the thumb, with its metacarpal bone, and the remaining three fingers, were removed. The flaps formed, however, were too seriously injured, and sloughed, the whole assuming an unhealthy and gangrenous appearance, while the integuments about the wrist were infiltrated and "boggy," and the patient suffered constitutionally. Consequently, on Nov. 16th Mr. Lupton re-amputated in the lower third of the forearm, cutting skin-flaps clear of the infiltrated area, and dividing the deeper parts by circular incision. The remaining treatment was precisely that of the former case; and the subsequent progress of this case was also satisfactory, the patient leaving the infirmary with a sound stump on February 1st, 1881.

KASHMIR HOSPITAL.

A PULSATING BRONCHOCELE; LIGATURE OF THE VESSELS; RELIEF.

(Under the care of Dr. Downes.)

In August, 1877, a boy aged about ten, having a large bronchocele, applied at the hospital. His appearance was altogether peculiar; he was rather deaf and slightly idiotic. The goitre was enormous, quite as big as the boy's head, and on both sides of the neck at the upper part of the tumour were arteries which pulsated forcibly. The vessels stood out on the surface of the tumour and pulsated with such force as to make the whole tumour move; the artery on the right side was much more distinct than the one on the left. It was resolved to tie these two arteries. The operation was much more difficult than had been anticipated, but was facilitated by the assistance of Drs. Williams and Ross of the Indian Medical Service. The patient was put under chloroform, and an incision was made about two inches and a half long through the skin over the pulsating artery on the right side from a point near the angle of the jaw, directly downwards, and the fascia divided carefully with a director. Here the difficulty began. The lobules of the hypertrophied gland were soon encountered, then with a director and the handle of the scalpel progress was very slowly made till the artery, which was accompanied by a large vein, was seen. The artery, notwithstanding its superficial appearance, was really at a great depth. An aneurism needle was placed under it, and the vessel tied with a stout silk ligature, leaving one end hanging out of the wound. The wound was closed with a couple of sutures, and then a similar operation was done on the other side. Next day the patient was feeling pretty comfortable, and there was no pulsation; after about three days severe fever set in suddenly; his temperature rose to 105° F. This high temperature was brought down to normal by a few doses of ten grains of salicylic acid. For two or three days the temperature rose again, but was always brought down in the same way. Every day the tumour was reduced in size; on about the eighth day it was only half its original dimensions. He then asked permission to leave the hospital, but he was urged not to go, at any rate until the ligatures had separated. However, on about the tenth day he ran away at night, carrying the ligatures with him. Two years afterwards this boy was said to be still alive, and the goitre to have quite disappeared.

Remarks by Dr. Downes.—Whether the above information be true or not, the fact that on about the tenth day the tumour was only half its original size, encourages one to think that wherever a very large goitre exists with pulsating arteries, a cure may be obtained by tying the arteries in the way above described. The operation is, however, somewhat troublesome, and not without danger. Such a high temperature is uncommon here after even very severe operations.

PATHOLOGICAL SOCIETY OF LONDON.

Eczema of the Nipple and Cancer of the Mamma.—Cystic Degeneration of Breast.—Cystic Disease of Kidneys and Liver.—Cystic Disease of Fœtal Ovary.—Cancer of Mediastinal Glands.—Localised Pneumothorax.—Aortic Disease.—Pulmonary Thrombosis.—Uterine Polypus.—Malformation of Hand.

The ordinary meeting of the Pathological Society of London was held on Tuesday, March 15th, Samuel Wilks, M.D., F.R.S., in the chair.

Dr. Thin showed specimens from and gave an account of two cases in which long-standing Disease of the Nipple and Areola was followed by the development of tumours in the breast. The first case was that of a single woman, aged forty-nine, whose breast was removed by Mr. Henry Morris. The nipple had been irritated for some weeks by a needle in the woman's stays six years previously to the tumour being observed. The irritation set up had never healed, and at the time of operation the position of the areola was marked by a bright red, moist surface two inches in diameter, a depression in the centre indicating where the nipple had been. The margin of this surface was sharply marked off from the healthy skin. On microscopical examination it was found that the centre of this area was denuded of epithelium, the cancerous growth forming the surface of a superficial ulcer. On the outer part of the area the epithelium was entire, but thickened, with elongated papillæ. The papillary layer of connective tissue was here destroyed, and the space it should have occupied was filled with exudation cells. The distinguishing features of the breast tumour were an excessive development of fibrous tissue and rounded clusters of cells, with a columnar epithelium lining the cavities in which they lay. On the edge of the growth the new epithelium was seen as small round columns with a central lumen, the condition termed by some pathologists adeno-fibroma. In the second case the breast was removed by Mr. George Lawson. The patient, an unmarried woman, aged fifty-seven, had suffered from the nipple affection for upwards of a year. There was no pain in the breast, no perceptible tumour, and no enlargement of the axillary glands. In the diseased skin in this case the epidermis was entire, but thickened, with long papillæ. The papillary layer of connective tissue had disappeared, and a stratum of exudation cells had taken its place. The breast consisted of a large mass of fat, permeated with narrow streaks of fibrous tissue. In these streaks a new epithelial growth was found in the form of tubes and round cell-clusters, with small cells and a distinct border of columnar epithelium. The narrow strips of fibrous tissue always separated the epithelial growth from direct contact with the fat lobules of which the large breast was almost entirely composed. The tumour would probably be called an adeno-lipoma. These two cases completed six which Dr. Thin had examined. Although these six cases all differ from each other in some respects, they agree in some essential points, and on these points of agreement Dr. Thin concludes that the affection of the nipple is neither eczema nor psoriasis, nor any known specific skin disease. It is a destructive papillary dermatitis, and he proposes that it should be called malignant papillary dermatitis. The breast tumours take their origin from the epithelium of the lactiferous ducts, and retain the specific characters of that epithelium. A complete account of an instance of the scirrhus, or parenchymatous type of cancer in connexion with this affection, has not yet been published. A local affection of the points on the surface of the nipple, which correspond to the mouths of the lactiferous ducts, has preceded in cases which have been well observed the extension of the disease over the surface of the nipple and over the areola. The hypothesis that best explains the fact that a malignant papillary dermatitis spreads superficially from the mouths of the ducts, and that an epithelial growth spreads downwards from them into the breast, is that the duct epithelium at the surface undergoes changes that are in their early stages already cancerous in their essential nature.—Dr. WILKS asked if Dr. Thin considered the skin affection the first development of the cancer.—Dr. THIN explained that the first change was found at the mouths of the lactiferous ducts, from whence it very slowly spread out, and later on formed a cancerous tumour deeply in the mamma; the change in the skin must therefore be cancerous in its nature.—Mr. H. MORRIS wished Dr. Thin could have obtained some cases in the earlier stage. From clinical observation he had found the affection of the skin indistinguishable from eczema, and it was only from the duration and intractability of the cases that the diagnosis of these cancerous cases could be made. In one case he had seen, three years before the appearance of a cancerous tumour, there was no evidence of any cancerous disease. In the same way cases of dilatation of acini and ducts may go on for a long time, and then either get well or inflame or become cancerous, the primary disease not having been malignant.

Mr. MOULLIN showed drawings of a case of Cystic Degeneration of the Breast. The patient was a single woman, forty years old. In eight months the tumour had become three times the size of the normal mamma. The tumour was removed; no trace of normal gland tissue was found, but the mass consisted of a number of cysts from the size of a pea upwards, lined by a smooth membrane, and containing gelatinous fluid; no intra-cystic growths. The cysts were shown to be derived from normal acini, which were separated from each other by circular growths of fibrous tissue, the epithelium increased in quantity, and became ultimately a single layer of squamous cells. On the outside of the acini delicate nuclei were seen, which developed into stellate cells, and, later on, spindle cells, parallel rows of which surrounded the cysts. A delicate structureless membrane was found between these cells, which had no connexion with the fibrous tissue of the mamma. The change had evidently taken place in all parts of the gland concurrently. The specimen was referred to the Morbid Growths Committee.—Dr. THIN stated that he had shown some specimens of the same change of the membrana propria of the acini of the mamma at the Medico-Chirurgical Society, and he thought Gross had described it too.

Dr. PYE-SMITH showed the Liver and Kidneys of a man, aged fifty-three, who had died of chronic interstitial pneumonia; of intemperate habits, he had suffered from cough for years; his arterial tension was increased, his urine abundant, pale, and occasionally albuminous. He died worn out by his pulmonary disease. Post-mortem: The kidneys weighed 64 oz., and were a perfect specimen of complete cystic degeneration of the whole gland with hardly any renal tissue left. The liver also contained several cysts, and was in addition lardaceous. The remarkable combination of cysts in liver and kidneys is still very rare, and was first described by Virchow as a fœtal and more rarely an adult change; and he remarked that in young children death took place from dyspnœa, the large cysts pushing up the diaphragm. Dr. Bristowe and Dr. Wilks showed two cases at this Society in 1855. The most remarkable point of this case is the man's age, and the fact that, although he had drunk heavily for thirty years, he had no symptoms of uræmia. The evidence is in favour of the cystic change being congenital in all cases; such cysts, we know, are present in new born children. Under the microscope all that is not cyst is kidney, and there is really a good deal of functionally active tissue; there is no adventitious growth.—Dr. N. MOORE thought the large quantity of liver and kidney tissue always found explains the fact of these patients living. The cases he showed last year evidenced this. Occasionally kidneys contain only a single cyst, he recently found one very large cyst close to the hilus in each kidney, the kidney structure being healthy; this was the minimum condition of the same affection.—Dr. WILKS asked if the disease of the liver was to be considered congenital.—Dr. GOODHART had examined the specimen shown very carefully, and had come to the conclusion that it was not congenital. The changes in the liver are in the portal canals, in which there is some cirrhotic material, which, however, is peculiar, being more varied than usual. The fibrous tissue is more embryonic, and the nuclei varied in size and shape, suggesting that it is a large overgrowth of muscular fibre, which, compressing the ducts, may cause cysts. There is also an increase in size of the peripheral lobular cells, with proliferation of their nuclei, which can be traced developing into the long muscular cells. There are very numerous cysts, some of which are probably formed by vacuolation of the cells. The fibrous tissue of the kidney is also peculiar, and like that in the liver. There is also a large overgrowth of the epithelium of the large tubes, which are then dilated into cysts. Thus in both kidneys similar processes are at work, but the tendency of the disease is shown by its different course in the two organs. The great majority of cases show no symptoms during life, and if it is really an overgrowth of renal tubes such might be expected. The Malpighian tufts seem to be considerably diminished.—Dr. PYE-SMITH would examine the specimens again, and make fresh observations from Dr. Goodhart's point of view. He had not noticed any increase of fibrous tissue in the kidney. Virchow has figured a great increase of fibrous tissue in the fœtal cystic kidneys. He had considered the cysts in the liver also congenital.

Mr. ALBAN DORAN showed a case of Cystic Disease of the Ovary of a Fœtus of seven months. The other ovary was perfectly healthy. The cysts were from one-twelfth to one-sixteenth of an inch in diameter, lined with ciliated epithelium, and containing dendritic growths; between them were smaller morbid cysts, also lined by ciliated epithelium. He had never heard of proliferating cysts in the fœtus, the only cystic disease of the fœtal ovary being described as developed from the Graafian follicles. There are no Graafian follicles in this ovary. A part of the Wolffian body normally remains in the normal ovary as epithelioid bodies; but the Wolffian tubes, of which these are the atrophied remains, would seem in this case to have enlarged into these proliferating cysts, at the expense of the development of the Graafian follicles. Micro-photographs of the specimens were shown.

Dr. S. WEST showed a case of Cancer of the Mediastinal Glands. A woman, aged forty, had had a tumour in the left breast seven years before death. Four years afterwards it became very painful and was removed two years and a half later. Six months before admission to Victoria Park Hospital she had pain on the right side, and was admitted with the signs of right pleurisy and mediastinal tumour, and some small lumps were found in the right breast. Post-mortem: The small nodules were found to be continuous with a great cancerous mass filling up the anterior and posterior mediastina and involving the whole right pleura. The lower lobe of the right lung had almost disappeared. The cancer was also widely disseminated over the peritoneum and into the liver. The connexion between the cancer of the left breast and the mediastinal cancer is interesting. The patient was tapped twice without success, although two pints of fluid were found after death. This was probably due to want of contractile power in the walls of the cyst.

Dr. S. WEST showed a specimen of Pneumothorax. A man aged twenty-two, ill for five months with cough, pain in left side and wasting, very extensive disease of left lung, with a large cavity in apex and base. He was suddenly seized with severe pain, expectorated a large quantity of pus, and the breathing became intensely amphoric, due to a localised pneumothorax with an opening in the lung 3 in. by 2 in. This case illustrated also the insidious origin of large pulmonary cavities.

Dr. MORRISON showed a Thrombus in the Pulmonary Artery. The patient had phthisis, gangrene of lung, and slow death; no embolic symptoms. At the post-mortem extensive pleural adhesions in right pleura: excavation and caseation of lung; a thrombus—partly recent, partly purely fibrinous—was found extending from the orifice to the extremest ramifications of the pulmonary artery, no clotting in veins.

The following card specimens were shown:—1. Disease of Aortic Valves, by Dr. S. West; there were only two cusps, in one of which was a large rupture. 2. Large Polypus growing from the Cervix Uteri, by Mr. G. H. Morgan. 3. Arrested Development of Upper Limb, by Mr. S. G. Shattock. There was webbing of the fingers, and on dissection the flexor longus pollicis muscle was found to send a tendon to the index finger to take the place of the tendon of the flexor profundus digitorum; this is a normal condition in the highest apes.

CLINICAL SOCIETY OF LONDON.

Fracture of the Spine treated with Sayre's Jacket.—Excision of the whole Tongue.—Round-celled Sarcoma of the Thigh treated by Amputation at the Hip-joint.—Bronzed Skin without Constitutional Symptoms.

The ordinary meeting of the Clinical Society was held on Friday, March 11th, J. Lister, Esq., F.R.S., in the chair.

Mr. Berkeley Hill showed a young man who had had a fracture of the Lower Dorsal and Upper Lumbar Vertebræ treated with Sayre's jacket, and who had recovered with only slight deformity of the spinal column. The patient fell twenty feet, and sustained fracture of the laminæ of the tenth dorsal vertebra and others, as far as the second lumbar. There was angular projection of these spines, and mobility of two of them. On admission to University College Hospital he suffered from severe concussion of the brain and spinal cord; next day he was in severe pain. Twenty-four hours after the injury he was placed on a table swinging at the middle, and on it raised and suspended by his head and shoulders, and a plaster jacket applied. There was immediate relief to the patient's sufferings, and no bad symptom followed, except loss of control of the left lower extremity for about thirty-six hours, and temporary extreme hyperæsthesia of a patch of skin on the dorsum of the same foot. The jacket was removed seven weeks after the injury. Now, 101 days after the accident, he can walk; his spine is strong, and the only sign of the serious injury is a moderate projection of the lower dorsal and upper lumbar spines and displacement of the laminæ of the eleventh dorsal and first lumbar backwards on the right side.—Dr. Buzzard observed that the patellar tendon reflex was much exaggerated on the left side, and that he had ankle or foot clonus on that side too, which is like that found in Pott's disease, where the paralysis is due to inflammation of the cellular tissue under the dura mater leading to a slight spinal myelitis. This lad has therefore some interference with the transmission of motor impulses up the lateral columns of the cord, probably from callus under the dura mater at the seat of injury.—Mr. Lister thought the mobility of the spinous processes very interesting; traumatic acute spinal curvature, which is most often without paralysis, is produced by fracture of the bodies of the vertebra, but here in addition to this there was injury to the spinous processes. It is impossible to say how this was produced; the curve must have been produced by a fall on the breech or head. He had never seen the spines injured from this cause. The result of the treatment in this case was most satisfactory; in ordinary cases the recumbent posture is sufficient.—Mr. H. Baker asked if Mr. Hill found the jacket useful when the man was up and about.—Mr. B. Hill considered that the youth had struck his spine in falling. He was kept in bed for three weeks, but the jacket was worn altogether seven weeks.

Mr. Barwell showed a case on which he had performed Excision of the whole Tongue by means of a small suprahyoid wound, and remarked on the best material for the loop of écraseurs. James A——, aged sixty, without parental history of cancer, had enjoyed good health till a year ago, when a small lump appeared at the side of his tongue. This was twice removed by ligature, probably inadequately, since on each occasion it quickly recurred. Admitted into Charing-cross Hospital on Feb. 11th, 1881, the whole tongue almost to the foramen cæcum was covered by an ulcerated, very dendritic growth, interspersed with deep ulceration. Saliva was constantly flowing from his mouth, and wetting his clothes. He was feeble from difficulty in eating, and had lost flesh; pulse 108, small and weak; no enlarged glands. The growth is the result of less than seven months. Two days later the tongue was excised. An incision about one-third of an inch long just in front of the hyoid bone exposed the raphé of the mylohyoid, which, being divided, bared the edge of the genio-hyoglossus. These muscles, separated with the handle of the scalpel, enabled the operator to feel the base of the tongue and the deep surface of the buccal mucous membrane. A Liston's needle passed into the wound entered the mouth just behind the left last molar tooth, the thread being left. The same was done on the right side, the loop of the cord being in the mouth. To the first cord the end of an écraseur wire was tied and so drawn into the mouth, its end being freed from the first thread was hooked into the loop of the second and drawn round the back of the tongue, out of the wound, and fastened to the écraseur. A Liston's needle was then passed into the wound through the middle of the tongue, and, guided by the operator's finger, was made to emerge well behind the disease. This needle guided the wire as it was tightened along the required line. As soon as the back of the tongue was thus severed, another écraseur was placed behind the incisor teeth, and its loop passed well down in the previous section. Thus the tongue was freed from the floor of the mouth and taken out from between the lips. If the écraseur be slowly used the operation is almost bloodless, and leaves no external scar or mutilation, and the tongue can be removed from immediately in front of the epiglottis with as much ease as the tip. As the sensory nerves are divided close to the jaw, the patient suffers hardly any pain afterwards. The wires supplied by instrument-makers are of steel, and tempered; they are too stiff, and the twisted wire-cords are not reliable. The soft iron wire used for park fencing, and supplied by Messrs. Newall, makes a very strong écraseur loop, and is so flexible as to be very manageable. Mr. Barwell also recommended the use of an écraseur which tightened the loop from both ends. The patient was shown. The stump of the tongue was in very good condition, cut off clean at the back. His general health had improved since the operation. He got up on the tenth day, and was ready for discharge two days later, but was kept in a few days longer.—Mr. Heath thought the great objection to Mr. Nunneley's operation was the very oblique section of the tongue. Mr. Barwell's operation got over this difficulty no doubt, but he thought it better to divide the sublingual tissues first with the knife or scissors. The tongue can then be drawn well forward, and its section far back easily made. Mr. Barwell's wire was good. It is very remarkable how the stump of a tongue grows. He had lately seen a case in which he had operated ten years ago, removing all the tongue. The appearance was as if none of the organ had ever been removed.—Mr. M. Baker thought that in all the operations like Mr. Barwell's it was impossible to prevent an oblique, and therefore unsatisfactory section of the tongue, especially in a diseased tongue, through which the needles placed in any position are readily pressed forwards. Where the disease has spread from the tongue it is better to strip up the mucous membrane from the floor of the mouth very freely. He was at a loss to see how the nerve could be divided so as not to leave its central end sensitive.—Dr. Poore said the man talked uncommonly well; he could say "theatre" and "tittle-tattle," which require tongue movement.—Mr. Barker asked why this operation is regarded as painless. Did Mr. Barwell consider this different from Cloquet's operation proposed fifty years ago. He also asked if this form of papilloma is often met with; he himself had only seen it once in a case under Mr. Marshall, at University College Hospital.—Dr. Gilbart Smith stated that he had recently had a patient with large papillary growths on the back of the tongue, one or two of which had entangled the epiglottis and caused difficulty in swallowing. He had seen other similar cases.—Mr. Lister thought the wire more satisfactory than others at present used. It combined pliability with sufficient strength. If the whole tongue was removed, the amount at present seen in the mouth was most striking; perhaps Mr. Baker's suggestion of the oblique section explained it; at any rate, the man had now a good two-thirds of the tongue. This was certainly a great improvement on Mr. Nunneley's operation. In cases of the removal of the whole or one-half of the tongue, he had found division of the jaw in the middle line most satisfactory; it is easy then to control the artery and to limit the excision. With other plans he had found it difficult to be certain of taking away enough without removing too much.—Mr. Barwell replied that he had never performed Syme's operation. The period of recovery after it was very long, and the proceeding was altogether very severe. Much blood may be lost by severing the base of the tongue in Paget's operation. This man lost one to one ounce and a half of blood, which was more than usually happens in his own operation. The operation is painless, because the nerve is cut close to the gustatory groove, and retracts away from irritation. If a large Liston's needle is used to fix the écraseur and firmly held it does not slip; the specimen showed the section to be quite straight. When the man left the hospital there was no appearance of the mass of tongue seen now, but a square gap reaching far back. He had no distinct recollection of Cloquet's operation, but he thought that in it a twine ligature was passed through the middle of the tongue.

Mr. BERKELEY HILL related the sequel of a case of Round-celled Sarcoma of the Thigh, treated by amputation at the hip-joint, in which the whole of the anterior flap sloughed, which he recorded in the Clin. Soc. Trans. The woman died six years after the operation from tuberculous pyelitis, which, during the last three months of her life, caused an abdominal tumour, which was mistaken for a new formation of the original growth. There were no growths of sarcoma found in any of the organs or tissues.—Mr. LISTER remarked on the great interest of the case, inasmuch as round-celled sarcoma is regarded as the most malignant form of sarcoma, but this was an example of its complete cure by local removal. It showed that our knowledge does not warrant us in speaking with certainty about the clinical history of any tumour from its histological characters; we are only warranted in stating the probability and the average course of such tumours; even a fibroma may prove malignant.

Dr. RADCLIFFE CROCKER read a case of general Bronzing of the Skin without constitutional symptoms, which had been shown at a previous meeting. The patient was a sailor, a native of North Sweden, aged twenty-two, of stout build, and in good health. The pigmentation came on after exposure to severe weather eight years ago, attained its full development in a few days, and has not extended or diminished since the first week, though he thinks he is paler sometimes than at others. The skin of the hands, backs of forearm, legs below the knee, and the mucous membrane are unaffected, but all the rest of the body is darker. The pigmentation has no sharp line of demarcation on the limbs and face, but shades off to the normal. The general hue was a yellowish-brown; but the neck, axilla, nipples, umbilicus, penis, and scrotum were brown or black. The abdomen and interscapular scapulæ were darker than the general hue; while the man who is on duty at night is supposed to be ready at a moment's notice. On the neck and axillæ were closely developed papillary growths about one-eighth of an inch long, and the natural lines of the skin were everywhere developed. Repeated alkaline baths and friction had no effect upon the discolouration. Microscopical examination of the skin of the abdomen showed the pigment to be deposited in the deeper cells of the rete, though pigment granules were to be seen both in the layers above close and to the papillary vessels of the corium. The corneous layer encroached upon the interpapillary part of the rete mucosum, so that that part formed a narrow layer of uniform thickness moulded upon the frillæ, which were elongated apparently by protrusion downwards of the interpapillary processes. The papillary growths upon the neck consisted of an oval growth of the papillary layer of corium, involving several elongated papillæ. The pigment was in the same position as elsewhere, but there was no alteration in the arrangement of the epidermic layers. Dr. Crocker was unable to offer any satisfactory explanation of the pathology of this condition, but negatived the idea of its being due to phtheiriasis, as was suggested when the case was shown to the Soctety.

Dr. CARRINGTON showed a case of Bronzed Skin without Constitutional Symptoms. J. B——, aged twenty-five, a native of Dantzic, was admitted into the Seamen's Hospital on February 16th, 1881. He did not become a patient on account of the condition of his skin, but for an attack of acute bronchitis. The patient left India during July, 1880. He had a very rough and lengthened voyage, and was continually wet through. About the eighth or ninth week out he began to suffer from severe pruritus, the parts affected being the back and arms. At this time he changed his clothes, and he maintains that his skin was then white as usual. On the second day he again changed his clothes, and he then found that his skin had turned brown. It was also dry and stiff, and on attempting to nip it between the fingers it cracked. His gums and teeth at the same time were perfectly normal. About a fortnight after he noticed an eruption of small pimples on his arms and legs; these became little blisters, and exuded fluid on their rupture. These latter ran together. His limbs assumed the appearance of being scalded. The weather was very wet and cold at the time of the attack, and there was no sunshine. The patient remained much the same up to the 15th week, when swelling of the legs supervened. In October, 1880, he landed at Rotterdam, and was there treated for three weeks by arsenic. He again took ship, and in October, 1880, he became a patient in the Newcastle Infirmary. He was there told that he was suffering from scurvy; but none of his shipmates had contracted that disease. Whilst in the infirmary he was treated with sulphur baths twice a day for a month, and was made to lie in bed between blankets. The colour of his skin did not alter during his stay. On Feb. 16th, 1881, he was admitted into the Seamen's Hospital for an attack of acute bronchitis. There is no history of syphilis. A year ago he had an attack of ague lasting three days. On admission he presented the appearance of a well-nourished muscular man, with black hair and blue eyes. His skin was dry and harsh, but fairly pliable. It was, with the exception of the face, hands, and feet, stained of a medium walnut-brown colour. There was a diffused uniform tint, mottled with a darker shade of brown. The colouration was more uniform on the trunk than on the extremities, where it became somewhat patchy. The areolæ of the nipples were very dark, and the axillæ and genitalia were also somewhat more deeply stained, but certainly not to a marked extent. He had also a well-marked attack of scabies affecting his feet and hands and buttocks. There was no pigmentation of the mucous membrane of the mouth and pharynx. The heart sounds were well marked and distinct. He had the physical signs of bronchitis. The liver dulness reached two inches below the costal margin. The spleen was not enlarged. The above description applies to him now equally as well as on admission, except that his scabies has been cured by treatment with sulphur ointment and baths. He feels perfectly strong and well—as indeed he has all along, except for his pulmonary trouble. A thin section of the superficial part of the skin showed abundance of pigment in the epithelial cells, but no fungus. A patch on each side of the chest has been well treated with a saturated solution of hyposulphite of soda, but without effect. With regard to a possible suggestion that the colouration was due to scratching from the irritation of the scabies, Dr. Carrington did not think this probable, both because the limits of the pigmentation far exceeded those of the supposed cause, and also because it was almost certain that he could not have been suffering from this affection all the time, the baths at Newcastle would then have cured it. This was the more probable, as he had rapidly recovered from this part of his trouble whilst under treatment at the Seamen's Hospital. The scabies had most probably been contracted at a later date. On his admission at Greenwich he was certainly not scorbutic; his gums were perhaps a little pale, but there was no hæmorrhage. Neither was it possible that the pigmentation was due to the slight attack of intermittent fever, for it is only found in the severe chronic cases.—Mr. LISTER said both the cases were very remarkable, from the sudden advent of the bronzing without any constitutional disturbance.

The meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

Annual Meeting.—Diarrhœa in Phthisis.—Defects of Vision from Railway Collision.

THE annual meeting was held on the 7th inst., F. J. Gant, Esq., President, in the chair. The report of the Council was read and adopted, and the ballot for the election of officers and Council for the ensuing year was taken, when the following were declared elected:—President: Dr. Broadbent. Vice-presidents: Dr. Wiltshire, Mr. J. W. Barnes, Dr. Quain, Mr. Brudenell Carter. Treasurer: Mr. Francis Mason. Librarian: Mr. Royes Bell. Secretaries in ordinary: Dr. Gilbert Smith, Mr. Edmund Owen. Secretary for foreign correspondence: Dr. Berkhart. Council: Mr. H. F. Baker, Dr. Percy Boulton, Dr. Bucknill, Dr. Sidney Coupland, Mr. Hamilton Craigie, Mr. Cumberbatch, Dr. W. H. Day, Dr. T. S. Dowse, Sir Joseph Fayrer, Mr. F. J. Gant, Dr. Clement Godson, Mr. D. H. Goodsall, Mr. Alfred Pearce Gould, Dr. W. R. Gowers, Dr. F. de Havilland Hall, Mr. Malcolm Morris, Dr. Heywood Smith, Mr. W. F. Teevan, Dr. J. C. Thorowgood, Dr. C. Theodore Williams. The subject for the Fothergillian Essay for 1883 was announced—viz., "The Treatment of Thoracic Effusion." The ordinary business was then proceeded with.

Dr. C. THEODORE then read a paper "On the Pathological Treatment of Diarrhœa in Phthisis." He enumerated three different varieties met with in that disease—1st. Disease from the primæ viæ. 2nd. Diarrhœa from ulceration of the intestines. 3rd. Diarrhœa from lardaceous disease of the intestines. The first was due to over-feeding, an error often committed in the treatment of phthisis, but easily remedied. The second was the most serious form, often proving fatal. Intestinal ulceration was detected after death in five-sixths of Louis' cases, in sixty-seven per cent. of Lebert's, and 81 per cent. of the Brompton Hospital cases, the amount of mucous membrane involved varying in different cases. The small intestine appeared to be the first attacked, and especially the neighbourhood of the ileo-cæcal valve. The stages of the disease consisted of—(1) Inflammatory hyperplasia of the solitary and agminate glands; (2) their conversion into small abscesses, or their caseation; (3) the discharge of their contents, leaving behind ulcers with smooth floors and sharp edges; (4) formation of grey tubercle in floor of ulcer, and its subsequent caseation, leading to extension of the ulcer, and its junction with neighbouring ulcers, until the whole intestine becomes a mass of ulceration. Thickening of the peritoneal coat generally takes place in the vicinity of the ulcer, and thus perforation was not common. Sometimes, however, it takes place and sets up local or general peritonitis, ending in death. Occasionally ulceration into a small vessel causes alarming hæmorrhage, and is known to heal, leaving a thickened scar, which causes a constriction of the intestine. The clinical symptoms of ulceration were, persistent diarrhœa, tongue characteristic of great irritation, pain in the abdomen, tenderness over the ulcerative process, and rapid wasting. Tenderness was in the author's experience more common in the left iliac region than in the right. The disease appeared in the small intestine, but created greater ravages in the large one, and advanced rapidly, and this was to be accounted for by the traction on the ulcers from the changes in the size of the colon during digestion, by the slow progress of the fæces and the disengagement of foul gases in this region, giving rise to conditions unfavourable to the healing of ulcers. Pyrexia depended upon the amount of ulceration. If only a limited surface was attacked it was absent, but if large tracts were involved the chart showed great extremes and marked fitfulness. Ulceration might exist without causing diarrhœa, but such cases were rare. The forms of diarrhœa in phthisis arising from lardaceous disease corresponded with colliquative diarrhœa. It prevailed, in the latter stages of the disease, and often alternated with the profuse night sweats. It differed clinically from the ulceration in the state of the tongue and nature of the stools, and was not necessarily attended with pain. The chief feature was the infiltration of the tissues, and especially of the villi and their vessels, with lardaceous material. The treatment of the first form was by alterative and antacid medicines and careful regulation of diet; treatment of the second form must be directed towards treating the ulcers, and consisted of rest in bed; the use of bland non-irritating food, counter-irritation to abdomen by poultice or blister; opium and sulphate of copper by mouth, or, if large intestine be involved, by opiate enemata combined with astringents and sometimes antiseptics. Morphia suppositories or injections containing opium were useful. Treatment of third form chiefly by astringents.—Dr. DE H. HALL thought in some of these cases diarrhœa was caused by swallowing fetid expectoration; he preferred the use of gallic acid rather than tannic.—Dr. JAGIELSKI referred to the necessity of treating these cases with due regard to the totality of the symptoms. He advocated restricted diet.—Dr. GILBART SMITH asked Dr. Williams if there was any relation between largyngeal phthisis and tubercular ulceration of the intestines.—Dr. HERON had seen marked benefit derived from use of the liquid extracts of bael in two drachm doses every four hours. He referred to the influence of locality in intestinal ulceration in phthisis.—Dr. WILLIAMS replied that in his hands tannic acid had proved more useful than gallic. He had not noticed any connexion between laryngeal phthisis and intestinal ulceration.

Mr. WORDSWORTH then read a paper "On the Defects of Vision attributed to Railway Collisions," speaking only of those cases in which no structural lesions can be discovered, of which he had seen about twelve who complained of dimness of vision, &c., and inability to apply themselves continuously to any occupation requiring the use of their eyes. On examination no signs of injury beyond slight hyperæmia of the fundus oculi were discovered. Yet in all the cases they received considerable pecuniary compensation for the injuries, on account of the unfavourable prognosis that had been given. He had ventured to give a more cheerful opinion as to the ultimate recovery, and, so far as he had been able to trace the cases since, he believed they all recovered on the settlement of their claims, and had resumed their wonted occupation. He remarked on the fact that medical men are seldom consulted in these cases except with a view to their assisting to obtain compensation; stated that in a long experience in hospital and private practice he had never seen any of these cases simply as patient either before or after the settlement of their claim for compensation. These are circumstances which give rise to a doubt whether they are really *bonâ fide* cases, and are entitled to the importance that has hitherto been attached to them.—Mr. MCHARDY asked what time elapsed after the accident before these ocular changes became visible.—Mr. BENTON mentioned a case of a lady having fallen on the side of her head; suffered from concussion. The right side twitches; sight affected three weeks after with hyperæmia of the left disc, which disappeared with complete recovery.—Mr. WORDSWORTH, in reply, stated the cases referred to by him manifested no retinal changes.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THE ordinary meeting of this Society was held on Thursday, March 10th, W. Bowman, Esq., F.R.S., in the chair. There was a large attendance of visitors in view of a discussion on the relation between optic neuritis and intracranial disease, which was opened by Dr. Hughlings Jackson, F.R.S. As this paper occupied nearly the whole evening, the discussion was adjourned to a special meeting, to be held on Thursday, March 31st. A second special meeting to receive and discuss the report of the Committee on Colour Blindness is to be held on April 7th.

In the first section of his paper Dr. HUGHLINGS JACKSON enumerated the various conditions under which optic neuritis was found. He believed that there was but one kind of optic neuritis from intracranial disease, but enlarged on the difficulty there was occasionally in deciding, during life, whether or not certain appearances in the fundus were owing to such disease or to Bright's disease. On this difficulty he submitted questions to the Society. Urging that optic neuritis might pass off under treatment leaving sight good, he asked what were the best signs by which past neuritis might be inferred when there was no obvious atrophy. He believed the changes were, in some cases, so slight that it would be scarcely possible from these alone to say there had been neuritis or any sort of swelling of the discs. In illustration of this he instanced a case he had recorded in THE LANCET, June 12th, 1880. He also asked if changes so slight as were left in that case were distinguishable from relics of slight changes in the discs induced in some hypermetropes by over-work of the eyes. In the next place he spoke of the rarity of uniocular neuritis in physicians' practice, especially in cases of tumour of the brain, proved post-mortem. Speaking of optic neuritis with good vision, he asked if, as some asserted, the neuritis here differed in kind from that found when sight was defective. He believed the difference was in the stage of changes; that in most, if not in all, cases of neuritis there was a pre-amaurotic stage, and that sight failed in the much later stage when the changes were clearing up. He drew particular attention to sudden temporary failures of sight in those cases of neuritis in which vision was usually good, asking what was the significance of those phenomena. Later in the paper he adduced them as evidence in favour of the vaso-motor hypothesis as to the production of optic neuritis by intracranial tumour. He spoke next of rapid permanent failure of sight in those cases of neuritis where heretofore sight had been good, one point of importance in regard to them being that the rapid failure might be erroneously attributed by the patients to remedies used or to atropine, or to ophthalmoscopical examinations. The next section was on the association of symptoms, excluding cases of tubercular meningitis. The first remark was that good general health goes practically for little in our estimation of the gravity of the situation in many cases of optic neuritis, even when sight is good. We all see, he said, healthy-looking, robust children, and adults, who are sometimes supposed by those who do not use the ophthalmoscope to have no intracranial disease at all, and who, nevertheless, have intracranial tumour; sometimes death occurs rapidly. Symptoms, in the usual sense of the word, might almost be said to divide themselves into two groups—localising and non-localising. He first spoke of the non-localising, or, as they might for other purposes be called, signs, the best signs at least, of local gross organic disease within the cranium. In most cases optic neuritis goes with headache, and often with vomiting. Sometimes the headache precedes the neuritis, and what is a very different statement, it very often indeed precedes failure of vision. The three symptoms point to local gross organic disease within the cranium, but are no further localising; they do not help us to determine in what particular part that disease is. The headache is usually intense; often it is paroxysmal, the patient being in the intervals apparently quite well. The vomiting is purposeless, and bile is often brought up. Hence the very frequent, almost invariable, diagnosis in the early stages of chronic cases of cerebral tumour (when sight is good or only slightly defective) from liver derangement, and in acute cases the diagnosis of "bilious or gastric fever." Or the patient, if a woman, is sometimes supposed to be only hysterical, until some unmistakable intracranial symptom, such as convulsion, suddenly alters the diagnosis; not unfrequently the patient, supposed to have a slight ailment, dies rapidly, or even suddenly. The routine use of the ophthalmoscope would save us from most of these errors in diagnosis. There is sometimes an acute illness as our first evidence of tumour. But there are degrees from such an illness to great chronicity. It is very important to bear in mind that optic neuritis occasionally occurs without any headache and without vomiting, and that the headache may be slight and the vomiting little. Another way of putting what had been said was to say that there were all grades of severity of the ailment, of which optic neuritis forms one part, from a condition which (when sight is good, as it often is) is mistaken for digestive derangement, or for hypochondriasis, or for hysteria, up to a condition like that of tubercular meningitis. At this juncture cases after neuritis has passed off, leaving or not leaving optic atrophy were spoken of. Suppose that there had been an acute illness from which the patient had recovered, except, perhaps, for defective sight, with some atrophy of his optic discs, there comes the question, Was the acute illness meningitis? For his (Dr. Hughlings Jackson's) part he believed it to be very much more probable that it was and remained a case of local gross organic disease. It is of no avail to say that the patient had "all the symptoms of a meningitis," for there are no symptoms known to be characteristic of meningitis only. Admitting that during the illness we might be unable to decide, he would take the mere fact of recovery as strong evidence against meningitis—not that he denied that recovery from meningitis occasionally happens. Autopsies alone could decide. So far as autopsies showed (held some time after recovery on return of head symptoms, or after death by some other cause) the evidence was strongly in favour of local gross organic disease rather than of meningitis, in the kind of cases referred to. From any or the whole of the three symptoms occurring acutely or chronically we cannot be certain of tumour, but in a chronic case we are in most cases right in predicting it. Suppose we were to feel certain of the existence of tumour, we should have, from the symptoms mentioned, so far as he knew, not a particle of evidence as to the locality of the tumour beyond that it was intracranial. Of course, if the pain be persistently one-sided, it is then a localising symptom. He then spoke of symptomatic conditions under which optic neuritis was rarely or never found. It was scarcely ever, if ever, found with ordinary epilepsy—the epilepsy of nosologists. It was very common with epileptiform seizures—convulsions beginning deliberately in some part of one side of the body. There were, however, a few cases of gross organic cerebral disease in which there are paroxysms like those of epilepsy proper, and occurring as in cases of epilepsy proper at intervals, health being good betwixt. If double optic neuritis be found in a case which symptomatically is like epilepsy proper, he would surmise that there was gross local organic disease. He had never seen optic neuritis in chorea. It was particularly to be remarked that optic neuritis was rare with complete persistent aphasia; not very uncommon with slight aphasia, nor with temporary complete aphasia, nor after right-side-beginning epileptiform seizures. The reason he supposed was that complete persistent aphasia often depends on clot or softening. On the other hand, tumour, the common cause of optic neuritis, was a very rare cause of complete aphasia. It was rare to see optic neuritis associated with extreme positive mental symptoms. In two cases he had seen the patients so affected became maniacal; in neither was there any local gross organic disease discovered post-mortem. Optic neuritis, although so often found with disease of the cerebrum or cerebellum, did not occur from mere destruction of any particular part of the encephalon. We are, the author said, not now concerned with defect of sight, but with the process of production of optic neuritis, with which there may or may not be defect of sight. Optic neuritis mostly occurs with intracranial tumour or some other adventitious product. The tumour may be in any part of the encephalon, anterior, middle or posterior lobe of cerebrum, pons Varolii, cerebellum (middle lobe, or right or left lobe); it may be at the base. Next, optic neuritis may not be found with tumours of different parts of the cerebrum, It may not be found with adventitious products in the cerebellum. A further fact in accordance is that optic neuritis may occur late in cases of cerebral tumour, this is, of course, in one way an important qualification of the last-made remark, but does not invalidate it; on the contrary, enforces the general statement that optic neuritis is not caused by mere local destruction of any part of the nervous centres. Optic neuritis exceedingly rarely occurs in cases of extensive destruction of brain by softening or clot (hence it is rare with complete aphasia and ordinary hemiplegia). Softening and clot affect a particular locality; and it might be said that in this is one reason for there being no optic neuritis. But it is sometimes found with tumour in this region. So then, because optic neuritis occurs with tumour of any part, and may not occur with tumour of many parts, because it comes on late in some cases, and because it is very rarely found with such widely destructive processes as softening and clot, it was inferred that it does not depend on local destruction of any part of the nervous centres. Optic neuritis points to the general nature of the local disease, but not to its particular nature. It is mostly produced in cases of gross local organic disease, but that disease may be not only tumour ordinarily so called or syphiloma, but cyst or abscess —may be an adventitious product of almost any fluid. We may safely make the generalisation that it points, most often, to a "foreign body" of some kind—of almost any kind. If a magician were to introduce a lump of wood into any part of a man's encephalon, it might, the author believes, produce double optic neuritis like that produced by a "foreign body" of pathological origin. There is no difference in the optic neuritis produced by tumour of any kind, by abscess or cyst. Tumour, or any other adventitious product, does not produce optic neuritis in its particular character as this or that kind of pathological product, but in its general character as "a foreign body;" and then, not because it destroys, but by some indirect action. Further evidence in support of this doctrine is that optic neuritis may exist when sight is good. And with or without defect of sight optic neuritis may pass off when the central disease remains. The several different lines of evidence agree in converging to the conclusion that optic neuritis results secondarily from a "foreign body." The hypothesis of Von Græfe, Schmidt, and the vasomotor hypothesis commonly attributed to Benedict, as to the mode of production of optic neuritis by internal disease, were then considered. Dr. Hughlings-Jackson thought the last mentioned hypothesis was the one least open to objection. The importance of microscopical evidence was urged, but was not spoken of by the author, as he had no work of his own of the kind to bring forward, and because, he said, others present were more competent to speak on that part of the subject than he was. He concluded by speaking of treatment. He urged prompt treatment of optic neuritis, with obvious exceptions, by iodide of potassium and mercury. He spoke strongly of the importance of the routine use of the ophthalmoscope in nervous diseases, since in that way the pre-amaurotic stage, the stage most amenable to treatment, would often be discovered. He believed there would be fewer blind people if the ophthalmoscope were used more frequently by routine in nervous affections, and treatment were begun before sight began to fail.

Reviews and Notices of Books.

The Brain as an Organ of Mind. By H. CHARLTON BASTIAN, M.D., F.R.S. London: C. Kegan Paul and Co. 1880. (International Scientific Series, Vol. XXIX.)

THE importance of comparative physiology in the study of the functions of the brain needs no vindication. Most modern discoveries regarding cerebral action depend upon it for their evidence or confirmation. The present time is opportune for the appearance of a work which has for its object the elucidation of the functions of the brain by the study of those functions throughout the animal kingdom. The past work of Dr. Bastian qualifies him well for the task. Besides his contributions to cerebral pathology, he has done good work at comparative anatomy, having won his scientific spurs over the nematoid worms before he undertook the researches on the "beginnings of life" with which his name is chiefly associated.

The book opens with a chapter on the "uses and origin of a nervous system" in the lowest animals, in which vital irritability precedes those differentiated manifestations of action which are immediately succeeded, in the progressive scale of organisms, by the presence of recognisable nerve elements. Here, of necessity, the speculations of Herbert Spencer and the observations of Romanes are chiefly followed. A description of the elements of a nervous system, fibres, cells, and ganglia, and of the nature and use of sense organs, follows. The nervous systems of molluscs, vermes, arthropods, fishes, amphibia, reptiles, and birds are then successively described, clearly and well, but with the subject of these chapters all students of comparative anatomy are familiar.

Probably some wonder has been excited by the introduction of the indefinite article in the title of Dr. Bastian's book. Why speak of the brain as *an* organ of mind? The answer to this will in part be found in the tenth chapter on the "scope of mind." Rejecting as absurd the old idea of a "metaphysical entity" using the brain as its organ, he finds the common notion of what should be included under the term "mind" altogether erroneous, and to be at once given up. Mind is not to be limited to the domain of consciousness, but should include "the functional results of all nerve actions on the side of ingoing currents and in the nerve-centres—whether these nerve actions are accompanied by a recognisable conscious phasis or whether they form what appear to be mere physical links between other nerve actions which are unquestionably in relation with definite conscious states." In the title, then, the word organ is used "merely in the sense that it is a part whose molecular changes and activities constitute the essential correlatives of those phases of consciousness known as sensations, emotions, thoughts, and volitions, as well as of a considerable part of the sum total of those other nerve actions which are unattended by consciousness." Thus mind, in the sense in which the word is often used, has to Dr. Bastian no existence; and the subject of the book, "The Brain as an Organ of Mind," is in effect the study of mind as the product of the action of nerve tissue.

Reflex action and unconscious cognition, sensation, ideation, and perception are next discussed, chiefly on the basis of the writings of Hartley, Sir William Hamilton, and Herbert Spencer, and the way is thus cleared for chapters on consciousness in the lower animals, on the nature and origin of instinct, on nascent reason, emotion, imagination, and volition, which are full of interesting facts, carefully culled from the writings of Buffon, Darwin, Spalding, Lubbock, and others, as well as from that repertorium of anecdotes—the pages of *Nature.* The anatomy of the brain of quadrupeds and the quadrumana is then described with much clearness and conciseness, rendered the more intelligible by many excellent illustrations.

The study of the human brain is introduced by a description of its development, followed by an account of the chief facts known regarding its size and weight, those collected by Thurnam being given with some important additions, especially relating to the connexion between brain-weight and mental power. The general relation between the two is subject to many exceptions. The heaviest human brain (67 oz.) as yet on record belonged to a man who could neither read nor write, but of twenty-three brain-weights of distinguished men all but six are above the average. That of Cuvier, as is well known, heads the list, although no less than four ounces less than the brain just mentioned. The brain of Professor De Morgan was only slightly above the average, those of Grote and Whewell were merely average weights, while that of Hughes Bennett, as well as of Tiedemann, were below the average. But, on the other hand, of eleven adult male Chinese coolies, whose brains were weighed by Dr. Clapham, in only two was the brain-weight below the average, and the mean weight of the whole was two ounces above the average—a remarkable fact, which Dr. Bastian explains as the result of a very long-continued antecedent civilisation, even of a low order.

The external configuration and internal structure of the human brain are then lucidly described, no less than one hundred pages being devoted to the description. In the latter the researches of Broadbent are chiefly followed. An outline is then given of the functional relations of the principal parts of the brain, according to the teaching of anatomy, experiment, and pathology. An attempt is made to explain the cross relation between the cerebral hemispheres and the opposite half of the body, which is not, however, very successful, the conclusion being that the cross relation was initiated in fishes in some "quasi-accidental manner, and that, in the first stage of its existence, it was, and still is, represented only by the decussation of the optic tracts; that in higher animals possessed of well-formed limbs, reflex and volitional movements of those of one side are often evoked in response to unilateral stimulation, so that in such creatures there would be a distinct advantage if other sensory channels, by decussating, were to be brought into relation at their central termini with those of the visual sense, and, finally, the same influences, whatever they may be, which determine this additional sensory decussation would lead to the establishment of the equally necessary sequential decussation of the motor channels for the limbs." In reference to this statement it should be pointed out that Dr. Bastian holds the view, which we thought had been effectually disproved, that the decussation of the optic nerves in man is complete. The difficult question of the functional relations of the cerebral hemisphere with one another, the duality of body, and the unity of mind, is then discussed. An interesting case is quoted from Dr. Strumpell in which there was general anæsthesia, loss of taste and smell, of the sight of the left eye, and deafness of the right ear, and in which the patient could at any time be sent to sleep by bandaging the right eye and closing the left ear. This is regarded as constituting proof of the activity of the sensorial regions of the hemispheres "for the production of what we know as consciousness." The fact that mental operations are unimpaired, and consciousness unaffected, although there is complete hemianæsthesia of the general and special sensations, is explained by the commissural function of the corpus callosum, by which both hemispheres are brought into relation with the sensorial stimuli from one half of the body, although it is admitted that the effect is "difficult to understand." The evidence of the possibility of a separate or dissimilar, but simultaneous, activity of the two hemispheres is of a very doubtful nature. It is held, however, that the intellectual powers are very much lessened by extensive disease of one hemisphere, although to this there are some striking exceptions. While "will," like "intellect," is single, we are, in its exercise, brought to the turning point where mental gradually give place to non-mental phenomena. The "out-going currents," which are thus set up have, it is held, no conscious side whatever, and "lie as much outside the sphere of mind as the molecular changes in the muscle which these out-going currents" evoke. It should be remembered, however, that this view, strongly held by Dr. Bastian, is opposed by some facts which have led very acute thinkers to entertain a different view. The cerebellum is regarded as a supreme motor centre for reinforcing and for helping to regulate the distribution of outgoing currents in voluntary and automatic actions. This view is based upon *à priori* reasoning from anatomical facts, and is not very easy to reconcile with many of the facts of experiment and pathology.

An interesting chapter deals with "Phrenology, old and new," and in this the modern discoveries in cerebral localisation are contrasted with the earlier views, of which a good historical sketch is given from Prochaska. The will and voluntary movements are next discussed. The mental processes concerned in volition are analysed, and their relation to the different parts of the nervous system, and the mutual relations of voluntary and automatic movements, are considered. One of the least satisfactory sections of the book is that in which an attempt is made to interpret the well-known experiments of Ferrier and Hitzig by the untenable hypothesis that the fronto-parietal centres are "rather sensory than motor." Dr. Bastian's views on this, and on the subject of the "cerebral mental substrata," appear to have been largely determined by his theories on the cerebral relations of thought and speech which are developed in the last chapters. He differs from most authorities on the subject in associating these almost exclusively with auditory processes, and this appears to have led him to assign to the sensory process the predominant, and indeed sole, part in the mechanism of thought—a view which is altogether opposed to the theories of such authorities as Wundt, Bain, and Hughlings Jackson.

The final chapter deals with certain further problems in regard to the localisation of the higher cerebral functions, especially in relation to the function of speech; and in an appendix is summed up the evidence in regard to the non-existence of any "muscular sense."

Dr. Bastian deserves much praise for the industry with which he has collected from various sources the materials which he has employed throughout the work. It bears the stamp of his own strong convictions. Although his views on some of the vexed questions of cerebral physiology will probably not receive general assent, the problems are everywhere discussed with conspicuous ability and untiring energy. The illustrations are throughout abundant and good.

Atlas of Histology. By E. KLEIN and E. NOBLE SMITH.
Part XIII. 1880.

THIS part concludes the volume. It contains drawings illustrating the outer and middle ear, the internal ear, the nasal mucous membrane, the spleen, and the ductless glands, including the hypophysis cerebri, the thyroid gland, the supra-renal body, and the glandulæ coccygea and carotica. The last chapter is devoted to the indirect division of the nucleus of the epithelial cell, and gives a detailed account of the process of cell division as observed in epithelial cells—a subject on which many essays have been recently written, and to which Dr. Klein has himself devoted much attention. The illustrations of this part are good.

When the first part of this work was published the need of a good Atlas of Histology was very great, and now that it is completed we think it fulfils the anticipations that were formed of it. The absolute number of plates is forty-eight, each plate having from eight to ten figures; and the text runs to 448 pages. No part of the body is omitted. A large portion of the illustrations and nearly the whole of the text are original, though some of the former are borrowed, with acknowledgment, from the best and most recent sources. Some appear to have been drawn by Dr. Klein's pupils from sections made under his supervision; and all may be regarded, from his known skill as a teacher, as representing the tissues as seen with the best microscopes, and with the most recent improvements in staining or injection.

The chief, perhaps the only fault of the work is in the somewhat loose and careless style of the letterpress. Dr. Klein both speaks and writes English well, indeed excellently for a foreigner; nor does he ever fail to make himself understood; but many of the sentences might with advantage have been revised or rewritten—a duty that might naturally have been expected to fall on his coadjutor.

The weakly illustrated parts of the work are those of the nervous and muscular systems, the latter in particular being in no way so far in advance of the drawings given by Mr. Bowman forty years ago as might have been anticipated from the recent technical improvements that have been made. The mucous and serous membranes, lymphatics, hair, and many other organs, are, on the contrary, very well drawn. With this book and the introduction to Quain's Anatomy by his side, the student or practitioner will learn all that has been recently done and all that he needs to know, unless he is himself making original observations on histology.

The Medical Register, 1881. London: For the General Medical Council, at Her Majesty's Printing Office, and published and sold for the Council by Spottiswoode and Co., 30, Parliament-street, S.W.

Proceedings of the General Medical Council and of the Executive and Dental Committees in regard to the Registration of Dentists from January 8th, 1879, to February 3rd, 1881. London: Spottiswoode & Co.

THE Medical Register of 1881 has been brought out much more promptly than its predecessors. It contains the register of 22,936 practitioners holding qualifications from the bodies named in Schedule A of the Act of 1858. This number exceeds that of the preceding year by 420. But it would be unsafe to assume that there was this difference in the number of persons practising. The number in the Register varies a good deal from year to year, according to the numbers removed under Section 14 of the Medical Act, which empowers the Registrar to send a letter to any medical man inquiring whether he has changed his address, and in the event of receiving no reply within six months to erase the name. Other names are removed on the score of death or by ceasing to practise. But it will readily be seen that under these heads great vagueness and variety of results may appear from year to year, giving only an approximation to the facts. Thus in 1876 there were 517 removed from the Register; in 1877 837; in 1878 1310; in 1879 1109; in 1880 841. A variable number of persons are restored annually to the Register under the same section. Evidence of death was ascertained in 1879 in 548 cases; in 1880 only in 526. The volume contains all the various Medical Acts of Parliament, with an index or page of contents, under which useful abstracts of the different Acts are given; the accounts of the General Medical Council presented to Parliament, the Dentists Act, and the accounts connected with its administration, &c., with various tables of great interest.

The volume bears evidence of careful editing, and, though not absolutely free from errors, is probably more so than any of its predecessors.

Another of the publications of the General Medical Council is before us—a small volume containing a Record of the Proceedings of the General Medical Council and of the Executive and Dental Committees in regard to the Registration of Dentists, down to those of the recent meeting. To those interested in this most unsatisfactory part of the Council's work this volume will be found useful.

ROYAL COLLEGE OF SURGEONS.

AT an ordinary meeting of the Council of the Royal College of Surgeons, held on the 10th inst., the Committee on Preliminary Examinations presented its final report, dated January 31st, 1881, on the series of inquiries contained in Dr. Haldane's communication of November 11th, 1880, with respect to the desirability of candidates for the medical profession being required, before they enter on the purely medical curriculum, to have been instructed and examined in the rudiments of Natural Science—Physical, Chemical, and Biological.

The Committee have considered seriatim the five questions proposed in Dr. Haldane's letter—viz., (1) What amount of knowledge of the rudiments of Natural Science might be fairly required from intending candidates for the medical profession? (2) Should candidates, before being admitted to examination, be required to adduce evidence of having been specially instructed in Natural Science; or should proficiency as ascertained by examination be considered sufficient? (3) At what period should the Preliminary Scientific Examination be passed? Should it take place before the commencement of the purely medical curriculum, or before the end of the first year thereof? (4) If a candidate have taken up a department of Natural Science as an optional subject at the Preliminary General Examination, should the fact of his having passed in it satisfactorily exempt him from appearing for examination in the same subject at the Preliminary Scientific Examination? (5) In the case of candidates who have passed the Preliminary Scientific Examination, what modifications could be made in the present medical curriculum and present Professional Examinations?

They recommend to the Council that the following answer should be returned to Questions 1, 3, 4, and 5—viz., That, in the opinion of the Council, it is desirable that intending medical students should be encouraged to study in one or more of the branches of natural science which are not included in the compulsory subjects of the Preliminary Examination required by the General Medical Council, and that a student who shall have passed an examination in one or more of such subjects should be exempted from any attendance on lectures [on the subject or subjects in which he shall have passed] and from similar examinations on those subjects during his professional education, but that such exemption should not include the practical instruction and examinations now required by any of the several medical authorities. And that to Question 2 the following answer should be returned—viz., That in the opinion of the Council, proficiency as ascertained by examination should be deemed sufficient.

The report was approved, adopted, and entered on the Minutes.

Mr. Gay moved, That in the opinion of this Council it is desirable that lectures delivered in the theatre of the College should conform, as far as may be practicable, to the terms and conditions of the trust in relation to the strictly Hunterian Lectures on Comparative Anatomy and other subjects as defined in that trust; and that they should, therefore, relate for the most part to such subjects as admit of illustration by the preparations in the museum. And that the President and Vice-Presidents, in regulating (as provided by the standing rule) the details of the proceedings relating to the lectures, be requested to communicate to the several professors and lecturers from time to time appointed the foregoing resolution of the Council. This motion was, for some unaccountable reason, not seconded, and fell through.

It was further resolved that a conversazione should be given by the College to the members of the International Medical Congress, to be held in London next August.

Analytical Records.

MEDICATED THROAT PASTILES.

(ALLEN & HANBURYS, PLOUGH-COURT.)

THESE pastiles contain convenient doses of well-known remedies, such as morphia, ipecacuanha, aconite, chlorate of potash, and citrate of iron, in a soluble gelatinous basis. They are well adapted for sensitive patients, and, indeed, as "elegant preparations" leave nothing to be desired.

SYRUPUS TONICUS (GALE'S).

(GALE & CO., BOUVERIE-STREET.)

A pleasant and convenient syrup, with but little inky taste. Each drachm is said to contain 1 grain of amorphous quinine, 1 grain of iron, and 1-32nd of a grain of strychnine. It has, therefore, the composition usually assigned to Easton's syrup, and has the advantage of being very much cheaper.

PREPARATIONS OF "THE PURE FOOD COMPANY."

(THE FOOD LABORATORY, 4, PRINCES-STREET, RED LION-SQUARE, LONDON.)

The following samples from the above Company have been sent to us:—

1. Milk food for infants.
2. Essence of beef, or pure beef-tea.
3. Solidified albuminous beef-tea.
4. Extract of coffee.

All the samples are of good quality, but they do not appear to possess any particular novelty.

TRIPOLITH.

(KROHNE & SESEMANN, DUKE-STREET, MANCHESTER-SQUARE.)

A slate-coloured powder, recently introduced from Germany as a substitute for plaster-of-Paris for fixative dressings. Gauze bandages filled with the powder are immersed in water and applied in the usual manner to the limb, which has previously been wrapped in a flannel bandage. A thin mixture of the powder with water is then applied to the gauze, and in five minutes the whole is hard. The powder is very light, does not appear to change much in the air, and sets very quickly. It seems, therefore, to be in all respects an improvement on common plaster, and it is said to be quite as cheap.

AESCULAP BITTER WATER OF HUNGARY.

(AESCULAP BITTER WATER COMPANY, SNOW HILL.)

The activity of this powerful mineral water depends mainly on the large quantity of the sulphates of sodium and magnesium it contains. It has been found to be a very efficacious aperient, and appears to act more rapidly than some others with which it has been compared.

THE SEAMEN'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—Is there any truth in the rumour that the Committee of the Seamen's Hospital have elected as their visiting surgeon a gentleman who is a local practitioner, in preference to other candidates who are connected with various London Hospitals, and that this gentleman is over forty years of age; notwithstanding that the committee in their advertisement fixed that limit to the age of applicants? Can there be any special reason for this peculiar action, when there is a resident surgeon, a Fellow of the Royal College of Surgeons of many years' standing, at the hospital, and the chief duty of the visiting surgeon is to aid and consult with that gentleman in cases of operative interference and severe emergency? If true, it would be a curious proceeding, as the "non-local character of the charity" is always laid particular stress on when appealing to the notice and pockets of the charitable public.—Yours &c.,

March 12th, 1881. A SURGEON.

THE LANCET.

LONDON: SATURDAY, MARCH 19, 1881.

MR. DODSON was not prepared to answer the question put to him by Mr. J. TALBOT in the House of Commons on the 14th inst., to the effect whether he was in a position to secure to the inhabitants of the metropolis the advantages which were intended to be conferred by the establishment of hospitals for fever and small-pox, under the provisions of the Metropolis Poor Act, 1867. Indeed, it would have been wonderful if he had been, having regard to the complicated nature of the subject as it now stands, at least in regard to small-pox. It would appear, moreover, from Mr. DODSON'S reply to Mr. TALBOT, that another appeal, touching, as we infer, the essence of the matter in relation to the Hampstead Hospital—namely, that it was necessarily a nuisance as assumed in the appeal on the legal question just determined by the House of Lords—is still open to the Managers of the Asylums Board. It is scarcely conceivable that the Asylums Board will avail themselves of this opportunity for further legal contention, but they have a month for consideration as to the course they will take, and it is possible that within the time they may persuade themselves that it is due to their public position, and the law under which they act, to leave no legal stone unturned. A deputation of the Asylums Board had an interview with Mr. DODSON on Saturday last, but reporters were not present. This interview was the first, we believe, after the decision on the appeal to the House of Lords, and it must be admitted that even in public offices there may be griefs too sacred to be bared to the public eye.

Although the decision on the first appeal to the House of Lords in the Hampstead Hospital case more immediately affects the metropolis in respect to hospital accommodation for the sick of small-pox, in reality it must be regarded as touching the subject throughout the kingdom. Every phase in the history of the Asylums Board and of the Local Government Board in its relations with it since the former Board had thrust upon it quasi-sanitary functions in its hospital administration has, as we now see, tended to make more and more clear the disadvantages arising from the administration of the metropolis in sanitary matters being dissevered from the laws governing the general sanitary administration of the kingdom. It has equally illustrated cardinal defects in the law as regards the provision of sanitary hospitals, whether as concerns the metropolis particularly or the kingdom at large. It is obvious that a law which gives authorities the power of erecting and maintaining hospitals for infectious diseases, whether for Poor-law or sanitary purposes, should also provide for the acquisition of land for sites for such hospitals after due public inquiry. It is, perhaps, correct to say that the want of such provision has been the greatest obstacle to the proper provision of hospital accommodation throughout the kingdom, and that it underlies much of the difficulty which the Metropolitan Asylums Board had to encounter, and contributed greatly to the disasters now befalling its hospital administration. But much as this defect in the fundamental law may have aided to bring about the present crisis in public hospital matters, it must probably be reckoned second in place to the fact that in the metropolis the execution of one of the most important public duties, in face of spreading epidemic diseases, should have been transferred from the sanitary authorities, who alone have the powers necessary to deal fully with these diseases, to a poor-law authority without any corresponding powers of combating them. This is the more remarkable as the Local Government Board, with whom the responsibility for this course rests, have been devoting themselves to a directly opposite policy of hospital administration in the provinces. There they have set their face against extensions of poor-law infectious disease hospitals, and have adopted the policy of urging sanitary authorities to provide such hospitals, as well for the reception of pauper as of non-pauper patients. Of the justness of this policy there can be no question. It regards the *disease* in its public health relations as the subject to be dealt with primarily and essentially, not the social status of the patient. A policy of this sort, joined with the requirements that the sanitary authorities *shall* (not *may*) provide hospitals and have the power to acquire compulsorily land for them, would best meet the public health necessities of the case; and the history of the Hampstead case taken in connexion with what is now occurring in relation to the Fulham and Homerton Hospitals, must make it abundantly clear that the metropolis will not get out of the hospital bog in which it is now floundering unless a similar policy is applied to it.

Great as the financial and administrative difficulties may be in the metropolis in dealing with this hospital question—difficulties before which both Mr. STANSFELD and Mr. SCLATER-BOOTH quailed, and in so quailing have left a crown of statesmanship within reach of Mr. DODSON, if he is disposed to seize upon it,—we do not believe that these difficulties are insuperable, and it ought to be possible to assimilate the management of sanitary hospitals in the metropolis to that which is being introduced generally in the country.

It is an important consideration that the present excitement against the Metropolitan Asylums Board hospitals is not against hospitals of this sort *per se*. It is rather against *big* hospitals as against *smaller* hospitals. This has been shown remarkably in recent letters to the public press from the pens of gentlemen who have been most forward in attacking the existing hospitals. This question must be considered separately, but it must be confessed that it opens out a line of thought which promises escape from present difficulties. It has been too hastily assumed that if what is asserted of the big hospitals be true it must be true also of smaller hospitals; but this by no means follows. For example, in the matter of incidental transmission of infection alone, from the visits of people from infected neighbourhoods to the hospital to inquire as to friends or relatives and patients therein, the chances of such transmission would be much greater in the vicinity of a big hospital than a smaller one. Nothing has yet occurred to make us doubt the wisdom of the Legislature in giving powers for the provision of hospitals by sanitary authorities in the Sanitary

Act of 1866, and that the policy of that Act in regard to hospital provision should not be maintained. It cannot be denied, however, that in regard to small-pox, the public excitement with respect to the provision of small-pox hospitals is getting perilously near a point which will make the establishment of such hospitals, whether large or small, impossible. However much this is to be regretted, it would be folly to deny the fact, and that there are not wanting good grounds for belief that the present small-pox hospitals are a danger to their immediate neighbourhoods. The possibility, then, of such a state of popular feeling as would render the establishment of such hospitals practically impossible, must be looked frankly in the face. It is a possibility which might for the moment be regarded with feelings of dismay by those who know best the habits of small-pox when retained in private houses, particularly among the poor. But in the end (and this may be said without the slightest degree of cynicism), it could not but prove advantageous to the public at large. After all, hospitals for small-pox are provisions against a contingency which should never occur among the inhabitants of these islands. With vaccination and revaccination at our command, *without cost*, if needs be, everyone may secure an almost absolute security against the disease. This security is practically now given to young children by the working of our public vaccination arrangements, and such children are being rapidly eliminated from the victims of small-pox. In the case of older children and young people who have come to years of discretion the choice of revaccination rests with themselves. Our small-pox hospital provision, for the most part, represents an expenditure out of the rates for saving these people from the results of their own carelessness or apathy. It may be a Christian policy to do this, but is it an economical or a prescient one? We commend the consideration to Mr. DODSON and the present Government.

◆

ALBUMINURIA without structural disease of the kidneys—a symptom of considerable interest and of much practical importance—was the subject of a recent communication by Professor BAMBERGER to the Vienna Gesellschaft der Aerzte. "Temporary albuminuria" it is often termed, but he suggests that "hæmatogenic" would be a more accurate term as contrasted with "nephrogenic," due to organic renal disease. This functional albuminuria is often trifling in amount, causing merely opalescence of the urine under the ordinary reagents, but the amount of albumen is sometimes considerable. It may occur in individuals apparently in perfect health, as ULTZMANN and LEUBE showed, and their observations have since been amply corroborated. It occurs also in febrile conditions, apparently as a result of the blood state, although standing in no direct relation to the pyrexia. Passive congestion and epileptic attacks also cause it. It is found in the convulsions from strychnine poisoning, but never in the abundant watery urine of hysterical states.

What is the origin of this albuminuria? An answer can be best given to this question by asking another. Why is not albumen always present in the urine, since all capillary vessels allow albumen to pass through their walls, and it would be remarkable if those of the kidney were any exception to the rule. WITTICH put forward the theory that the urine which passes through the capillaries of the Malpighian bodies is always albuminous, but that its albumen only serves to nourish the epithelial cells of the urinary tubules, and that the albumen which is not thus used passes back into the circulation. This theory presents the difficulty that it assumes that the epithelium of the kidney is nourished in a different way from all other epithelium, but it has the support of the pathological fact that when the epithelium is removed from the kidney, albuminuria occurs. And yet, on the other hand, intense fatty degeneration of these cells may exist, as, for instance, in phosphorous poisoning, and no albumen may appear in the urine; while in cases of transient albuminuria, in which, for instance, albumen appears in the urine after an epileptic fit, it is not conceivable that this explanation will suffice. ROSNER has brought forward an experimental objection to WITTICH'S theory. He placed small fragments of fresh kidney in boiling water, and thus fixed the albumen in the position in which it was produced. In diseased kidneys he found coagulated albumen in the urinary tubules, but he never found it there in healthy organs.

Physiologists assert that albumen is retained in the kidneys on account of the pressure-conditions of the circulation; the pressure is sufficient to lead to the transudation of water and saline substances, but not of albumen. It may be asked, however, How does the pressure here differ from that in other capillary vessels? The size of the renal arteries in proportion to the organ, the structure and arrangement of the capillaries, all point to a high blood-pressure in the kidneys, a condition in which substances only slightly filtrable should readily pass through, albumen among them. HEIDENHAIN goes further, and asserts that nothing of the nature of filtration occurs in the kidney, basing his assertion on the relation which the amount of urea bears to the quantity of urine.

Another explanation which has been given is that the epithelial covering of the smallest renal capillaries keeps back the albumen. Mucous membranes only allow the escape of an albuminous fluid when they are denuded of their epithelium. This theory, however, holds good only for the living kidney; albumen passes out of the kidney after death in spite of the epithelium. Moreover, the epithelium is not equally retentive of all varieties of albumen; egg-albumen, for instance, injected into the vessels rapidly passes out in the urine; serum-albumen does not, while the albumen of red-blood corpuscles, the hæmoglobin, rapidly passes out in the urine if the corpuscles are destroyed.

RUNEBERG has asserted that the amount of albumen which passes through animal membranes varies inversely as the pressure; the lower the pressure the greater the amount of albumen. Hence he believes that when albuminuria is not dependent on structural alterations in the kidneys, it is to be ascribed to the diminution of pressure in the Malpighian glomeruli. He thus accounts for the albuminuria of mechanical congestion of the kidney, in which the blood-pressure in the aortic system is commonly much lowered. The diminished quantity of urine in this condition supports this theory, and also the beneficial influence of digitalis as a remedy for the condition. Febrile albuminuria he ascribes to the same mechanism, the lowered blood-pressure from the enfeebled state of the heart. He has not, however, sufficiently distinguished the influence of the two important factors in the circulation, the pressure and the rapidity of the movement of the blood. In order to ascertain afresh the influence of the first of these factors, Bamberger has performed the experiment of stretching two similar membranes (amnion or pericardium) over cylinders, and allowing equal quantities of albuminous fluid to filter through them, with and without the pressure of a layer of oil poured upon the top. In the first experiment he took some pleuritic fluid, which contained 1·174 albumen. He found that in the cylinder in which the pressure was the greater, the absolute quantity filtered and the absolute amount of albumen were greater, but that in both instances the percentage of albumen in the total filtrate was the same. A second experiment with ascitic fluid, containing a large amount of albumen gave similar results. Quite recently Gottschall and Hoppe-Seyler have performed similar experiments, and have obtained the same results. Runeberg's theory thus also becomes untenable, and there are other experimental objections to it. When the renal arteries are tied the blood-pressure falls considerably, but the kidneys become congested, and blood and albumen at once appear in the urine. Moreover, in febrile states, the albumen often appears a few days after the commencement of the pyrexia, and while the pulse is still full and bounding. Neither an increase nor a diminution of the blood-pressure will alone account for the transudation of albumen. The only other condition to which it can be referred is the retardation of the blood-current. Albumen is slowly filtrable, and may only pass through when it remains for a comparatively long time in contact with the wall of the vessel. The same relation is seen in inflammation, in which first there is a retardation of the blood current, and then the exudation of an albuminous fluid. This, however, is probably not the only factor. The epithelial cells of the Malpighian glomeruli may lose their function without presenting any anatomical alterations—a hypothesis which can be neither established nor disproved. Another factor is the vaso-motor action, consisting in either paralysis of the vaso-constrictors or irritation of the vaso-dilators. By dilatation of the vessels a retardation of the blood current can readily be produced. In this way the origin of the febrile albuminuria can be readily understood, since vaso-motor disturbances are frequent in that condition, apart from any direct relation to the amount of pyrexia. If the whole nervous system, and therefore also the vaso-motor system of the kidneys, is deranged by an epileptic attack, albuminuria may readily arise in the same way. The same explanation—the hypothesis of a slight vaso-motor disturbance—affords also the most ready explanation of the occasional albuminuria of apparently healthy individuals. At the same time, the possibility of chemical changes in the circulating albumen must not be forgotten. Under some conditions albumen is probably formed which behaves in the same manner as egg-albumen or paraglobulin, and, unlike serum-albumen, filters easily, and may thus appear in the urine. This fact, indeed, renders it doubtful whether the phenomena are to be explained at all by the mere physical conditions. We know nothing of the reason why the different kinds of albumen are excreted with various degrees of readiness, and whatever condition is the cause of this difference may also, when deranged, be the source of the temporary albuminuria which still constitutes so great an enigma.

It seldom happens that the plain truth can be—or is—spoken about any subject of warm controversy until long after the heat has subsided. When the dispute issues in legislation on the lines laid down by the dominant party, there is almost sure to follow a period of more or less sententious reserve on the side of the defeated. It may be bad taste to show elation in times of success, but dominant parties habitually triumph over their vanquished opponents, and if they have been fired with anything like enthusiasm in their enterprise, and have felt that the work in hand was a worthy and useful undertaking, it is difficult to call in question their full right to take credit for the achievement. When the success gained has been less complete than the substantially victorious party reasonably expected it to be, it is natural that there should be considerable disappointment and some bitterness. Nor can there well fail to be an attempt to carry the conquest to a fuller conclusion. All this is perfectly intelligible, and in many respects as it should be. If no strong and deep feeling existed, there could be no earnestness, and in the presence of strong and deep feeling there must always be something of animosity in any contention. We are not, therefore, in the least degree surprised to find that the promoters of the attempt to arrest scientific inquiry by vivisection have formally renewed the onslaught. They took up arms in what they conceived to be the cause of humanity against inhumanity, and they succeeded in passing an Act which virtually affirmed the principle for which they contended—namely, that it was wrong to inflict suffering on the lower animals in the search for relief and remedy for the sufferings of mankind. The provisions of the new statute could not, however, at the moment be made sufficiently repressive to crush out the practice of vivisection finally and instantly. It is only natural, we concede, that the "anti-vivisectionists" should return to the charge. Since the measure of triumph achieved they have, indeed, stooped somewhat low to conquer more completely. Their mode of carrying on the agitation has been, to say the least, unscrupulous and undignified; but let that pass. It has never been our *rôle* to offer a determined opposition to the movement. The sympathies of every heart must be stirred against wanton cruelty of any kind, and in so far as it may have been proved, or even reasonably suspected, that pain *was* inflicted on the lower animals without absolute scientific necessity, our sympathies have gone out with those who tried to stay the hand of the heedless or too persistent investigator. Meanwhile we have felt, as all concerned in the pursuit of physiological science and the art of healing must feel, that without vivisection, secrets, a knowledge of which is essential to the discovery of means and ways of cure for human maladies, could never be wrung from Nature. And this persuasion has held us in a position at once unsatisfactory to ourselves and open to the reproach of not being clearly defined. The appearance of a new Bill bearing on its back the names of Sir Eardley Wilmot, Mr. Samuel Morley, and Mr. Firth, and having for its specific object the *total* abolition of vivisection, supplies us with a not un-welcome opportunity of placing our views explicitly before the profession and the public. In short, an occasion has arisen for speaking the plain truth about vivisection, and we shall not shrink from uttering it.

Vivisection is a scientific necessity; and inasmuch as it is just as idle to try to stay the progress of science as it is to oppose the rising tide on the sea shore, the attempt to suppress this particular mode of investigation cannot be ultimately successful. Notwithstanding the assertions made by men with warm and feeling hearts, it is an incontrovertible fact that nearly all we *know* of the living organism in health and disease has been learnt by vivisection, either intentionally performed or, as the phrase goes, "accidentally" accomplished. Vivisection has been practised in all ages and countries, more or less extensively. It is the analytical method applied to the study of organic life, just as the demolition of the earth's crust by the geologist's hammer is the analytical method applied to inorganic nature. The fact that the living animal feels is an untoward contingency, but it cannot qualify the major consideration. The dissection of the dead organism is tributary or complementary, and may well be made preparatory, to the dissection of the living body; but in the long-run we must find ourselves face to face with the grim truth that it is the *living* body which science requires, and sternly demands, to explore, and which sooner or later she will explore in spite of all the hindrances which sentiment and humanity may throw in her way. If vivisection is totally abolished in this country practical physiologists will have to go elsewhere. This is what has, in fact, happened since the passing of the Act limiting vivisection. The most eminent explorers are working on the Continent and in the United States, and the only effect of persecuting them in one place is that they fly to another. It is a little vain-righteous of us to put away the evil—as we think it—with one hand while we eagerly grasp all the good that comes out of it with the other. The great bulk of the information which has enabled physicians to treat diseases with new precision in recent years, and which has already led to the lengthening of many useful lives, is the outcome of vivisection. The "anti-vivisectionist" does not stop to inquire whether the gift by which he is healed in the hour of sickness, or some one dear to him is snatched from the jaws of death, has been offered to idols! He is wise in his reticence. Now that the heat of the controversy has passed away, those members of our profession who spoke unadvisably in the interests of a crusade against cruelty must perceive that they overstated the case when they declared, or admitted, that vivisection was unnecessary. It is indispensable and irrepressible. The aim to minimise the recourse to it was humane, the attempt to abolish it altogether is absurd.

The Bill before us writes its own epitaph in the 7th clause:—"This Act shall not apply to intervertebrate animals." The promoters of the measure do not dare to push their initial—and, we must be excused for saying, pretended—proposition to its obvious and logical consequences. The feeling of the invertebrate animals is not less acute in relation to their own organisms—looking to their colder blood and comparatively less sensitive nervous systems—than the feeling of the vertebrates. If no pain is to be inflicted in the interests of science we must desist from vivisection of every kind. It is a contemptible affectation of pharisaic humanity to take credit for protecting the dog while we allow the frog to be dismembered for our information and advantage. It is mean to seek ease and remedy for our ills at the expense of suffering inflicted on the animal one remove farther—as we suppose—from community in the life we are so selfishly eager to prolong. Science tells us that *all* animals feel, and that the measure of feeling is in each case proportionate to the power of endurance, so that practically the *pain* is in all instances pretty nearly equal under corresponding conditions. Hereafter it may be demonstrated that plants, too, have feeling, and then the proposition on which the anti-vivisectionists base their movement will have been carried to the extreme. This new Bill is *not* a measure for "the total abolition of vivisection," and no such provision can ever be made. It was well to impose restrictions on the practice of operating on living animals for the purpose of scientific investigation. The Act embodied an expression of public opinion—on the subject of the use of anæsthetics, and the needless recourse to vivisection for mere purposes of demonstration,—which it was useful, and therefore right, to make; but the endeavour to abolish vivisection altogether is as shortsighted as it is impracticable. If a more stringent Act on this subject were passed to-morrow, the average number of vivisections now performed would not be reduced. The legislative exploit would simply be offering a little additional incense to our national vanity. The operations denounced here would be performed elsewhere; and then, as now, we should hug the comforting sense of superior humanity, while we bid eagerly for the increased information science might gain in her "cruel" quest.

◆

THE letters which we publish to-day on the Fellowship of the College of Surgeons of Edinburgh must, for the present, end a discussion which has been very useful, though we could wish that it had not been necessary. The subject of it has already been ventilated in Parliament, and it can scarcely now be disposed of without a great evil being remedied. One of our correspondents very naturally speaks in the tone of one aggrieved. He takes us back to a time when the Fellowship was only to be had on terms of examination, and when it was regarded as an honour and a distinction; and he is grateful for the exposure of a system by which it is virtually sold, and, so far from being an honour, is rather the reverse. The other correspondent also approves of our criticism, but thinks it ought to extend further, and to other corporations, and that it is scarcely fair to restrict our censure to the Scottish Corporations. He reminds us that the Fellows of the College of Surgeons of England without examination exceed, or in 1880 did exceed, in number those who gained their Fellowship by examination. This is, no doubt, true. But in saying so one is slaying what has been already killed. The system, so far as the English College of Surgeons is concerned, is virtually at an end. The Fellowship is practically only to be had by examination, and by an examination that is undoubtedly not easy. The exceptions to this rule are alone enough to prove it, as will be seen by anyone who will refer to an editorial note at the end of the letter of F.R.C.S. Edin. in last week's LANCET. The case of the Irish College of Surgeons is similar.

There remain the cases of the Royal College of Physicians of London and the King and Queen's College of Physicians in Ireland. In the case of the London College, Fellows, it is true, are elected and not examined. But they are elected on conditions very unlike those which obtain in the case of the Edinburgh College of Surgeons and the other Scottish Corporations. In the latter case Fellows are elected on showing that they possess a *minimum* qualification, medical or surgical, as may be the Fellowship to which they aspire, from any Corporation, and producing ordinary testimonials. In the case of the College of Physicians in London, on the other hand, a Fellow must be not merely a licentiate of the College, but a member, and to become either of these he must pass a corresponding examination. Not only so: the election is by the whole body of Fellows, and is a process of selection of men, already *members by examination*, who most commend themselves to the general body of Fellows by their scientific or professional position. No one could maintain that there is any comparison between such a system and that of the Scotch Corporations.

The case of the King and Queen's College of Physicians is more open to question. Those who were licentiates of the College before December 12th, 1878, may be admitted members without fee or examination, under certain conditions. In other cases there is an examination. Only members of the College are eligible to the Fellowship, and elections to the Fellowship are by ballot.

The Government has promised that the whole system of higher qualifications shall be inquired into by the Royal Commission which is to be appointed. That such an inquiry should be necessary, as it certainly is, after twenty-one years' operation of the Medical Act, is the most serious condemnation of both the Medical Council and the Medical Corporations. It is fully that time since the Medical Council expressed its condemnation of a system by which high sounding titles were granted without examination, and it was no care of the Medical Council to see that its opinions were accepted. It had an easy conscience, that could go on registering honourless honours without compunction and without complaint to the Privy Council.

◆

WE had hoped that the recommendation of Lord CRANBROOK'S Committee, that in the matter of honours and rewards "the Medical Department should be judged rather by the standard for combatants than by that for non-combatants," would have been carried out by the military authorities. But we regret to find that on one of the first opportunities for doing so—the distribution of honours for services during the late Afghan campaign—this principle has been ignored by the Horse Guards, and the recommendations for the appointment of medical officers to the Order of the Bath have been made in accordance with the long established practice, and bestowed, as of old, with a niggardly hand. It is too bad that when the principle recommended by a Committee appointed to inquire into the grievances of an important branch of the public service has been accepted and adopted by the Secretary of State for War it should be in the power of the authorities at the Horse Guards to disregard the decision, and to continue a system of injustice which has, in past days, tended greatly to bring the Medical Department into such disrepute that it was impossible to get candidates for it to come forward, and which contributed to bring about a state of affairs that rendered a liberal expenditure of money necessary to rehabilitate the department. To expect justice for medical officers from the Field Marshal Commanding-in-Chief appears, from his habitual action towards them, to be hopeless. We have received so many letters from correspondents complaining of this omission that we feel bound, in duty to the profession, to call the attention of Mr. CHILDERS to the injustice which has been done on the present occasion, in the hope that he, as the responsible head of the army, will intervene to obtain for the medical officers that recognition to which their services entitle them. The events of the wars in Afghanistan, Zululand, and the Transvaal have shown too clearly how unjust it is to class them as non-combatants, and on no other ground can we understand the niggardly distribution of honours to them. We trust that Mr. CHILDERS will show himself above such petty feelings as seem to have influenced the Horse Guards, and that, in addition to rectifying the present regrettable omission, he will take steps to prevent a repetition of it, either by laying down imperative rules for the conduct of the Horse Guards in such matters, or by removing from them the duty of recommending medical officers for honorary distinctions, and taking it into his own hands with the aid of his responsible and impartial advisers.

Annotations.

"Ne quid nimis."

THE ROYAL COMMISSION ON THE MEDICAL ACTS.

SO far the Government have made no change in their proposals for the constitution of a Royal Commission on Medical Acts *minus* medical men. We cannot alter our opinion that in this course the Government is altogether wrong. It would be difficult to select an instance in which a Commission to carry out an investigation affecting a large profession or body of men has been appointed without including representatives of that profession or body of men. What has the medical profession done that it should be treated so exceptionally? It would be an insult to the medical profession to argue that there is anything in medical men, or in the organisation of the profession, to justify the Government in treating them as they would not treat lawyers or ecclesiastics, railway and mining authorities, shipowners, &c. It is quite true that the public interests are the first to be consulted by a Royal Commission, but there are also professional interests, and there is no real antagonism between the two. But this exclusion of medical men, by whomsoever sanctioned or advised, cannot be real. It is impossible that a body of laymen can proceed for one day without consulting medical men. And their thoughts in the absence of medical commissioners will infallibly turn to members of the Medical Council, which has so fatally misled Governments for the last ten years, and whose administration is now challenged. It is strange for a Liberal Government so to treat the members of a liberal profession. It would be far better to put on the Commission two or three members of the General Medical Council itself, and two or three medical reformers, that the real questions at issue between them may be duly raised, sifted, and settled.

THE DEATH OF THE EMPEROR OF RUSSIA.

HER MAJESTY'S subjects of all classes are deeply impressed with the horror of the politico-social situation in Russia. Regret at the lamented death of the Emperor, sympathy with the Imperial Family in its bereavement, and indignation stirred by the hideous crime which has been committed, possess the public mind here as in every civilised community. If we of the medical profession are more particularly interested in the medical features of the sorrowful event, it must not be supposed that we are not keenly alive to its other aspects. The reports which have reached us from various sources as to the precise nature of the injuries sustained by the deceased Emperor are conflicting, but they agree in showing that the direct effects of the explosion on the lower limbs constituted the proximate cause of death. The bones of both legs below the knee were severely fractured, and the soft parts lacerated to an extent and in a manner which seem to have astonished the experienced surgeons in attendance. The fingers of the right hand were crushed, there were wounds on the face, but the stress of the injury fell on the lower extremities. The immediate cause of death was loss of blood. This is a most regrettable feature of the case. As soon as medical aid was procured, doubtless such measures as were practicable were taken to arrest the hæmorrhage; but a long interval elapsed before this assistance was available! There would seem to have been no medical men at hand, a wholly unaccountable circumstance, considering the perpetual peril to which the Emperor was exposed; and not one of those around His Majesty appears to have been acquainted with the ordinary measures for the temporary stoppage of the flow of blood. We must postpone, for the present, a critical summary of the medical aspects of this deplorable case; but it is a duty to give expression to the very painful feeling left on the mind of the medical profession in England by the imperfect reports which have been published.

SECONDARY SUTURE OF NERVES.

AMONG the advances in nerve pathology and therapeutics of the last few years, not the least interesting and important have been the practice and results of surgical interference. The operation of nerve-stretching has established itself as a recognised proceeding, and recent experience is rapidly extending its sphere of usefulness, although its *rationale* is involved in considerable obscurity. The primary suture of divided nerves has been practised for several years, and many recorded and unrecorded cases testify to its value. Quite lately, however, the secondary suture of nerves has been practised, and although not with uniform success, yet with most encouraging and, we may add, surprising results. The best test cases are those of union of severed motor nerves, for the return of sensation in parts supplied by a divided and then sutured nerve is open to another explanation than that the nerve trunk has again become capable of conducting sensory impressions. For this reason a case of Langenbeck's, of secondary suture of the musculo-spiral nerve, is very valuable. The patient, a labourer, thirty-one years of age, received a severe contusion of the outer side of the right arm below the middle, which was attended with paralysis of the extensor muscles of the forearm and hand. An abscess subsequently formed and was opened. Two-and-a-half months after the injury, as the paralysis continued, Langenbeck cut down upon the divided nerve, freed its ends, which he found lying two centimetres and a half apart, and united them by a catgut suture. Although there was considerable tension, healing took place by first intention, and nineteen days afterwards the extensors reacted to the induced current, and after a month and a half considerable active extension movements were possible. Mr. Hulke has brought forward at the Clinical Society a case in which he had united the cut ends of the median nerve nearly six weeks after the injury, and another case in which he practised a similar operation on the ulnar nerve fifteen weeks after division, and in each instance there was distinct evidence of restoration of function. Esmarch and Létiévants have each had a case of suture of the musculo-spiral nerve, the former successful. These and other like cases afford great encouragement not only to unite by suture the cut ends of nerves in recent wounds, but, where necessary, after cicatrisation is complete.

MEDICAL REFORM.

A CIRCULAR has been issued to members of the profession residing in Yorkshire inviting them to attend a meeting convened for Wednesday, April 6th, at 5 P.M., in the Philosophical Hall at Leeds, to consider the subject of medical reform. We concur in the opinion expressed in this circular that the success or otherwise of medical reform must depend on the opinions which the profession hold on the subject; and shall therefore watch with considerable interest the result of this meeting. Those who have been mainly instrumental in inciting this movement are anxious, as we are, to ascertain the feeling of the profession on this important subject, and we know of no more effective means of arriving at a correct conclusion on the subject than by observing the spirit evinced at a meeting of this kind. It is not so much by what is said on such occasions that the feeling of the profession is to be gauged; it is the tone and the number of men attending such an assembly which make it a valuable test of the earnestness of the professional mind in the matter of medical reform. Probably there is no more appropriate place than Leeds in which to hold a meeting such as we have referred to. Its flourishing medical school, association with the names of many distinguished members of the profession, together with the proverbial shrewdness and steady purpose of Yorkshiremen, must render the expression of opinion emanating from the meeting of the 6th of April a fair indication of professional opinion regarding medical reform, and will largely influence the action of other towns with reference to the inauguration of meetings for a similar purpose.

SUICIDE IN PRISON.

THE Appendix to the Third Report of the Commissioners of Prisons contains the results of an inquiry as to suicides committed in local prisons during the five and a half years ending March, 1879. It appears that during this period no less than 81 cases of suicide occurred in the various English prisons. The statistics now published point exclusively to one fact—that the tendency to suicide is greatest during the first few weeks of imprisonment; the 81 cases reported upon included 31 during the first week, 19 in the following three weeks, and 17 during the second month of residence in prison. Thus 67 of the 81 cases of suicide occurred during the first two months of imprisonment. No prisoner committed suicide who had been more than twelve months in confinement; and it is noticed that, relatively to number of prisoners, the proportion of suicides in local prisons was more than four times that occurring among convicts undergoing penal servitude. Of the 81 cases of suicide in prison, no less than 28 occurred among prisoners under remand or awaiting trial, the remaining 53 occurring among those undergoing sentence. As the average annual number of prisoners under remand or awaiting sentence was only 1270, against 18,530 undergoing sentence, it follows that the proportion of suicides in the five and a half years was equal to 22 per 1000 in the former, against 2·8 per 1000 in the latter class. These figures should serve as a warning to prison authorities as showing that it is eight times as necessary that those prisoners under remand or awaiting trial should be as closely watched with a view to the prevention of suicide, as those undergoing sentence. It appears, moreover, that among an average number of 1712 prisoners sentenced to penal servitude, and awaiting removal from the local prisons to the penal servitude or convict gaol, nine committed suicide in the period under notice, whereas only ten suicides occurred during the same period among an average population of 10,000 prisoners undergoing sentence in convict prisons. The Medical Inspector in his report appears justified in concluding that penal servitude inspires fear and dread, which is not found to be justified by actual experience. The last report shows that during the year ending March, 1880, the number of suicides in prisons declined from 18, which was the average annual number during the five and a half preceding years, to 12. Notwithstanding this reduction the proportion of suicides was just six times as large among the prison population during the year under notice as it was among the population of England and Wales, at the ages 15—55, during the year 1879. It is easy to understand that the tendency to suicide is greater among prisoners than among the general population, but that actual suicides are proportionally six times as frequent among them, as in the general population at similar ages, does not reflect credit upon the management of prison authorities, who cannot be unaware of this tendency to suicide, especially in those recently committed to prison, and who should secure the means for more effectual watching. It may be hoped that the proportion of suicides in gaol will be still further reduced under improved prison management.

BATTEY'S OPERATION.

THE operation of spaying women suggested many years ago for certain conditions by the late Dr. Blundell, and revived within the last ten years by Dr. Trenholme, Dr. Battey, and Dr. Hegar, is still *sub judice*. It has been proposed and practised for several conditions—as severe dysmenorrhœa; profuse menorrhagia, threatening life; certain cases of amenorrhœa, in which grave constitutional disturbance was, or was believed to be, dependent on the activity of the ovaries; certain mental or nervous states believed to be dependent upon the ovaries, as threatened insanity, epilepsy, and hystero-epilepsy. The operation is one, however, which has not as yet received the full acceptance, nor the entire condemnation of the profession. That the profession as a whole have suspended judgment upon it is right, because the data for the formation of a just and correct opinion of its value are as yet insufficient and inconclusive. It was at first proposed under the belief that removal of the ovaries would immediately bring on the menopause, and at once arrest the uterine functions; but the physiological theory of the dependence of the uterine upon the ovarian function has been called in question, and it cannot be denied, however strong the evidence may be for the old view, that there is a good deal of evidence in favour of the new. But the fact that the physiological basis of the operation is called in question would not be sufficient to condemn or even to suspend judgment upon it, were its results uniform and certain. It is, however, well known that these results are neither uniform nor certain. In some cases the menopause has been brought about, while in others such has not been the result. In some the nervous symptoms and suffering have been cured, in others relieved; in others, again, there has been no improvement. The best results appear to have been obtained where the operation was performed in cases of fibroid tumours of the uterus; but here, again, the results have not been uniform. Moreover, the mortality has hitherto been high. If the operation should prove in its results to be of great value, there can be little doubt that means will be found to reduce the present large mortality. But there are other difficulties to be overcome before it can be fully accepted as a legitimate proceeding. Just as there is a difference of opinion as to the part played by the ovaries in health, so there are great differences of view as to the part played by them in disease. The difficulties of diagnosis are at present enormous. Perhaps few observers would be found to agree as to what phenomena are to be considered as reflex, arising from disease of the sexual organs, and what not, and what could be referred to the ovary and what not. It is true that some specialists ascribe much to the uterus or to the ovaries; but we cannot help thinking that they ride their hobby somewhat hard, and that much of what is now called uterine or ovarian neuroses, is so called upon totally insufficient evidence. It is by no means impossible—nay, it is not improbable, that many of these are really dependent on general or central, and not on local pelvic conditions. Lastly, supposing that ovarian mischief is evident, and that the nervous, mental, and other phenomena are dependent upon it, a difficulty at present insuperable may be met with—viz., the ovaries may be so bound down by adhesions, so encased in tough membranes, that their removal is not practicable. Such cases have already been met with, and portions of the ovaries have been left behind by some of the most accomplished operators. This fact is of the greatest importance in the discussion of a proceeding of so grave a character. To render spaying a legitimate operation, it is necessary to prove: (1) the dependence of the symptoms, for the relief of which the operation is proposed, upon diseased ovaries; (2) the inefficiency of any other means for their relief or cure; (3) the feasibility of the removal of the diseased organs. We cannot help thinking that if these considerations have due weight, the number of cases in which the operation will be undertaken will be limited. For reckless operating in cases in which the above conditions are not fulfilled, we have no sufficiently strong words of condemnation.

A PIECE OF GOOD IRISH WORK.

WHEN so many painful circumstances in Ireland occupy public attention it is gratifying to give publicity to a most satisfactory and creditable experiment on the part of the Guardians of the Cork Union. This has reference to the boarding-out of pauper children. The Cork Union speaks with the authority of eighteen years' experience of this system, and they show that it contrasts favourably with the workhouse plan. It is cheaper, the children are remarkably healthy and happy, and in a large majority of cases are adopted by the foster parents. The foster parent is appointed on the recommendation of local clergymen, and is generally either a small farmer or a well-to-do labourer. From 1862 to the present there were 650 children removed from the workhouse and boarded out in several favourable districts, seaside or mountainous, in which the union abounds. Of this number 209 are at present boarded out, and 417 have been adopted by their foster parents and are going on well, twenty died, and four have returned to the workhouse and are now ready to go out to service. We have seldom recorded a social or sanitary experiment which gives us more pleasure. Here are 417 children at the age of thirteen, on the application of their foster parents, taken off the rates and off the roll of pauperism to start fair in the world. There must be much good in a race that can so deal with one of the saddest social problems. Much importance is attached by the committee to the supervision of relieving officers, assisted by clergymen and ladies, and to the periodical reports of the dispensary medical officers on the health of the children. This report, signed by the chairman of the Boarding-out Committee, Mr. Wm. D'Esterre Parker, is worthy of the serious attention of the Local Government Board and of all guardians. On the score of economy alone the experiment is entitled to attention. A child in the workhouse at Cork costs the union 3*s.* 6*d.* a week, or £9 a year; while outside, over two and under five, it costs 11*s.* 6*d.* a month, or £6 14*s.* a year; and over five and up to thirteen 12*s.* 2*d.* a month, or £7 6*s.* a year.

PNEUMOCONIOSIS.

IN a pamphlet, entitled "De Las Pneumoconiosis," by Rosalino Rovira y Oliver, the following conclusions are arrived at. The inhalation of pulverulent substances is not inoffensive, as maintained by Parent-Duchâtelet, but is, on the contrary, likely to occasion serious pathological processes, the gravity of which will be greater in proportion as the powders inhaled are harder and more rough. The pathological processes excited, which have received the name of pneumoconiosis, are distinct from pulmonary tuberculosis and from caseous pneumonia. In every point of view—etiological, pathogenic, pathological, syndromic, semeiotic and therapeutic — they deserve separate and special recognition and description in all works on medicine. In consequence of the different methods in which the pulverulent particles act, distinct states or kinds of pneumoconiosis are produced, and these may be grouped into the two following forms. First, those forms of disease which are produced by powders possessing but little hardness, and, secondly, those resulting from the action of powders the particles of which are very rough and hard. This mode of grouping proves of service in determining the treatment, for in those forms which result from the inhalation of soft powders the remedies employed should be those which augment the secretory activity of the respiratory tract, together with appropriate dietetic treatment. In the case of diseases produced by hard powders, on the other hand, no pharmacological substances are of service, but the patient should be at once withdrawn from further exposure to the dust, and placed under more favourable hygienic conditions.

SEATS FOR SHOP WOMEN.

WE wonder how many of the humane ladies who are just now rushing from shop to shop making their purchases for the season give a thought to the sufferings entailed on the young women serving behind counters and in show-rooms by the stout refusal of their employers to provide them with seats for use in the brief intervals of business. We have from time to time during the last year printed a list of firms which, in response to our appeal, have consented to provide their female *employées* with sitting accommodation, and—which is another and a greater matter—to allow them to make use of it. Ladies have this reform in their own hands. It is useless to form associations for promoting the movement, and it is weak to perpetually "petition" the shopkeepers. If customers would simply *see* that seats are provided and used, and patronise only those establishments where the necessary measures are carried into effect, the thing would be done. Unfortunately, however, when a lady visits a shop she is all engrossed with the wares offered for sale and her own wants, so that the "movement," to which she has perhaps given her name and money an hour or two ago, is forgotten. There is not the slightest necessity for any special organisation in the matter. If the feeling of sympathy for suffering, often expressed, were real, those who profess it would not fail to impress the fact on the shopkeepers to whom they give their custom. Nothing less than the commercial logic of business returns will bring this matter home to the consciences of retail shopkeepers. And the recourse to this convincing mode of reasoning is open to to every lady who is in earnest in the matter; but how few are!

THE NEW CROWN REPRESENTATIVE FOR IRELAND IN THE GENERAL COUNCIL.

THE Crown has appointed Dr. Alfred M'Clintock as its representative in the General Medical Council. We gladly express our approval of the appointment, which is in accordance with the wishes of a deputation from the Dublin Obstetrical Society. Dr. M'Clintock is worthy of this honour on personal grounds. He is an accomplished physician, an ex-Master of the Rotunda Hospital, the editor of the Sydenham Edition of Smellie's "Treatise on the Theory and Practice of Midwifery," and the author of many finished works on Obstetric and Gynæcological subjects.

The appointment of an obstetric physician is an innovation of some significance, and very creditable to the Government. The diseases of women and children make up a large share of medical practice, which has been too lightly regarded by the General Medical Council. All English attempts to get this branch of practice recognised have been unavailing. But better days are, we trust, coming, and the Medical Council will ere long, perhaps, represent all departments of medical practice.

FOOD OR DRUG?

WE are glad to see that the *Standard* has admitted to its columns letters which call attention to the nature of some of the dietetic drinks which are just now much in vogue in teetotal circles. It is so manifestly unadvisable to make an habitual use of articles which should be used only when wanted, and under medical advice, that it is only necessary to allude to the fact that many persons nowadays are drinking as table drinks what in reality are medicines, and we are sure that our readers will agree with us in strongly condemning the practice. One of the letters makes a suggestion in which we thoroughly agree, and have often taken occasion to urge—viz., that drinks which bear popular names should have their exact compositions affixed to the label. We do not think that this should be merely optional, but in justice to the public it ought to be enforced by law. A really good article would benefit if its composition were known, and if the sale of trashy substances were lessened in consequence, only the vendor would suffer, while the public would gain immensely. The Adulteration Act should be applicable to patent and secret articles of diet as well as to foods of recognised composition, and this will only be possible when the law requires every packet or bottle to bear a distinct and definite statement of its ingredients.

THE POLICE COURT *v.* THE SURGICAL AID SOCIETY.

THE Surgical Aid Society must be a society of considerable merit. Nothing less would explain its survival, in spite of the most injurious impressions produced on the public mind by its rules. Last week a poor woman appeared at the Guildhall Police Court, and applied to Sir Thomas S. Owden for assistance to procure a medical appliance for her husband, who was suffering from rheumatism. The poor woman was in the usual difficulty of applicants to the Society. The cost of the article she wanted from the Society was 50*s.*, and she required ten letters of 5*s.* each. By much labour she had managed to procure seven letters, but the last three were too much for her strength and leisure, and so she came to the police magistrate. It is a strange inversion of experience to be driven from a charitable society to seek help in a police court. The magistrate naturally said, that to require the full value in tickets of an applicant was not charity, but trade; and the public will agree with him. He gave the applicant 20*s.* The police magistrate is not supposed to be either an authority as to the therapeutic value of appliances for the treatment of rheumatism, or a charitable institution. But the public will easily forgive his good nature, and condone the gift of 20*s.* from the poor-box.

HOSPITALS FOR WOMEN.

"COUNCILLOR TAIT, in seconding the resolution, said the Women's Hospital had become of great importance, not only to the town of Birmingham, but to the country at large, for not only had the staff been able to do the work which they had undertaken to do better than it had been done anywhere else, but they had done work which had never been done anywhere else previously. Although he was bound to speak it with becoming modesty, still, as a member of the staff of a hospital doing altogether new and original work, he could not conceal from himself the pleasure he had in sharing in it, nor did he think that those who subscribed to the charity ought to be in ignorance of the fact that that hospital had become a pioneer in surgical work, the staff having performed in its wards operations which had never been attempted elsewhere."—*Birmingham Daily Gazette*, March 9th, 1881.

It is scarcely credible that the above paragraph was spoken by Mr. Lawson Tait, the surgeon to the Women's Hospital. We earnestly trust that the contributions made to medical literature by this sage councillor have more foundation in fact than the above mass of nonsense; for we can assure him that had he made himself acquainted with the literature of the diseases of women, he would have found that no legitimate operation is performed in the Birmingham Hospital for Women which is not done with at least equal success elsewhere.

MEDICINE IN RUSSIAN TURKESTAN.

THE official *Gazette of Turkestan* states that at the beginning of the year there were in Russian Turkestan 2 urban medical men, 18 district, and 24 midwives, and that during the year 1879 they had given their attention to 28,868 patients, of whom 6931 were Russians. The military medical men, moreover, had had under care 1260 patients. The patients attended among the indigenous population included 13,106 Sartes, 5144 Khirgises, 865 Tartars, 563 Kaschgarians, 165 Uzbecks, 146 Hindus, 144 Persians, 69 Chinese, 31 Afghans, 30 Bukharians, 24 Karakalpacks, 23 Turcomans, and others.

SEA-WATER BATHS.

WE have long advocated the organisation of a system by which sea-water baths might be placed within the reach of residents in London. A company, having for its object the promotion of this enterprise, is, we are glad to see, about to be established. There are to be tepid swimming sea-water baths for gentlemen, and a similar provision is to be made for ladies. Hot sea-water baths, and douche, and shower baths are included in the programme. The sea-water is to be brought to the baths in specially constructed steam vessels. This, it is said, can be accomplished in a few hours, and the sea-water is not expected to lose any of its qualities *en route.* The projected establishment is to be erected on the Thames Embankment. Without in any way committing ourselves to the details of the scheme, or offering an opinion as to the probabilities of practical success, we most cordially commend an effort which has the high guarantee of Mr. Brill's experienced management. The well-known proprietor of the Brighton Baths brings special knowledge to the enterprise. If it fulfils the purpose set forth it cannot fail to confer very substantial advantages on a large class of our fellow citizens.

A GOOD EXAMPLE FOR GUY'S.

A WISE and proper recognition of the medical staff has lately been shown in the government of St. Bartholomew's Hospital, at the instance, we believe, of Sir Sydney Waterlow. Sir Sydney proposed that Sir James Paget, Sir George Burrows, Dr. Farre, and Mr. Luther Holden should, in consideration of their services to the hospital, be made governors. The proposal was accepted. Such a course is creditable equally to both parties—to the governors and to the members of the medical staff.

IT is a remarkable circumstance that our "Obituary" this week contains notices of the decease of two gentlemen—Mr. Godrich and Dr. Richards—who were associated with the late Mr. Wakley in his successful effort to secure a due pecuniary recognition of the services of medical men as witnesses, and as examiners for Life Insurance Societies.

MR. GEORGE SMITH, of Coalville, in again calling attention in the newspaper press to the sad condition of the children on board canal boats, in spite of recent legislation, states that within the last three weeks seven deaths from small-pox have occurred on such craft between London and Birmingham.

BY the anti-liquor law of the State of Kansas, to come into force in May next, physicians are required to make affidavit that they will not prescribe intoxicants except in cases of actual illness, whilst druggists must file all prescriptions containing alcoholics in the same way as they do all kinds of poison.

WE are informed that Dr. Cory has been appointed Director of the Government Animal Vaccine Station in progress of establishment in London. On Tuesday last, accompanied by Dr. Cameron, M.P., he inspected Dr. Cook's Vaccine Farm at Manningtree, Essex.

THE death, on the 23rd ult., of Dr. G. A. Otis, surgeon of the United States Army, is announced. At the time of his death Dr. Otis was engaged in the preparation of the third volume of the surgical series of the Medical and Surgical History of the Rebellion.

PROFESSOR CHARCOT has been summoned to Russia professionally, and while there the medical profession have shown him much honour. A banquet, organised by alienist physicians, has been given him in St. Petersburg. Eighty guests sat down at table.

THE honorary degree of LL.D. has been conferred on David Ferrier, M.D., by the University of Aberdeen.

AT an ordinary meeting of the Birmingham and Midland Counties Branch of the British Medical Association, held on the 10th inst., the following resolution of the council of the branch was received and adopted:—"That in the opinion of this council the promoters of the Skin and Lock Hospital have acted irregularly and prejudicially to the public interest in the election of medical officers by mere nomination at a private meeting convened by circular. The public and the profession have a right to require that public medical offices shall be publicly filled, and that they shall be open to competition."

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Kendal.—Dr. Page's report for the borough of Kendal during the year 1880 gives the general mortality at the "high rate" of 23·2 per 1000 of the estimated population (14,300). The cause of the unusual mortality is assigned to the fatal prevalence of scarlet fever, a concurrent outbreak of measles contributing to the result. The birth-rate of the borough for the year was 33·8 per 1000. Dr. Page discusses the influence of "masked" attacks of scarlet fever upon the efficacy of precautionary measures and upon provisions for the notification of infectious diseases; and he is inclined to the opinion that insanitary circumstances exercise an influence upon the fatality of the malady. He is of opinion, moreover, that early hospital accommodation for the isolation of cases would have proved helpful in controlling the spread of the disease. The chief administrative event recorded is that the Sanitary Authority of the borough has determined to undertake the removal of house refuse. We do not quite understand whether this includes excremental refuse, but we trust it to be the case, for it seems particularly paradoxical that the authority should concern itself with the removal of the least harmful sort of refuse, while the most harmful is left to accumulate in the midst of the houses.

Dublin.—Dr. Cameron reports for the five weeks ended 29th January, 1881, a death-rate in the annual ratio of 42·1 per 1000 persons living, a higher rate than for the corresponding period of the last ten years. The greater mortality was chiefly due to diseases of the organs of respiration. The only zymotic diseases showing increase during the period were "fevers," and of these principally typhus. But Dr. Cameron states that the present epidemic of that disease is not extending, and he has "no apprehension of its assuming anything like the proportions of former outbreaks of this formidable disease." In his remarks upon the inspection of "tenemental dwellings" Dr. Cameron observes:—"The denizens of the kind of tenements which we are from time to time closing up are of the poorest classes of society. The great majority are labourers and their families; fruit, fish, and vegetable dealers; hawkers, vendors of small wares, and not a few street beggars. Such people, unfortunately, too often reduce to a filthy and dilapidated state houses at first tolerably clean and in good repair. When they are turned out of one house they go into another, and soon render it also 'unfit for habitation.' For the use of the great majority of these people cottages ought to be constructed by the municipality under the provisions of the Labouring Classes' Dwellings Act. These cottages being under proper supervision by the authorities, could be kept in a better sanitary condition, and their inmates under some kind of discipline (so far as keeping their rooms clean, &c.), than appears to be practicable in the case of the lowest class of dwellings owned by private landlords."

Ilfracombe.—Dr. Slade-King reports for 1880 a birth-rate of 24·8 per 1000 population, and a death-rate of 13·8. Increasing attention appears to be given to the sanitary arrangements of this favourite health-resort. Important sewerage works were carried out during the year, and the means for an earlier and completer removal of house-refuse were improved. The sanitary authority here, as sanitary authorities elsewhere, has its difficulties with builders who endeavour to evade the carrying out of plans of new buildings deposited with the sanitary authority and approved by them. But the authority seems determined not to have its by-laws set at nought.

Kingston-upon-Thames.—Mr. C. M. Shirtliff reports for this borough in 1880 a death-rate of 17·3 per 1000 population, and a birth-rate of 38·0. He writes favourably of the general sanitary condition of the district, but he thinks that the sanitary authority should, in view of satisfactorily meeting any epidemic, first seek provision for the compulsory notification of infectious diseases (this is spoken of as "the very step" they should take), and next ("next to which in importance") provide a disinfecting apparatus and a hospital for infectious diseases. This seems to us very like "putting the cart before the horse."

St. Marylebone.—Mr. Wynter Blyth has issued the first of a series of annual reports under the ingenious title of "The Sanitary Chronicles of St. Marylebone." The illness and death of Dr. Whitmore prevented his making a report for 1879, and Mr. Blyth, although only lately appointed to the medical officership of health of the parish, was unwilling that a gap of two years should exist in its sanitary annals. He has, therefore, prepared the report for 1880 now before us. Although he tells us that he has given "considerable labour" to the preparation, it appears to us to present in more than one place indications of haste. In an account of Dr. Robert Dundas Thomson, the first medical officer of health for St. Marylebone, which is couched in language that seems to imply the only work in which he had been employed in by Government was "to make some experiments relative to the feeding of animals;" no allusion is made to the important work Dr. Thomson did for the Committee of Scientific Inquiries of the General Board of Health during the Cholera epidemic of 1854; and the disproportion between the data given on p. 19 and the inferences sought to be drawn from them, detract from the reader's interest in the report.

ST. PANCRAS AND ITS "DUST."

The vestry of St. Pancras has deferred the question of "dusting" arrangements for the parish until October, which, as we take it, means that the inhabitants of the parish are once more to be exposed (or are likely to be exposed) to the terrible nuisance from which they suffered during the summer and autumn of last year, from the scandalous imperfection of the arrangements for removing the dust. At the meeting during which the motion for further delay was carried out, one member claimed that £1400 had been saved on the last year's dusting, and another set forth as subject for congratulation that, of 24,000 dustbins in the parish, requests for removal of the contents (complaints of non-removal said another) had only been received in respect to 18,000! Not a word appears to have been said about the sanitary discomfort of the parish during this reign of filth, or, if said, the subject elicited but small remark. It is high time that Section 43 of the Public Health Act, 1875, which enables householders in the provinces to deal more or less effectually with local authorities who undertake the removal of dust, should be made to apply also in the metropolis.

SANITARY HOSPITAL, NEWCASTLE-UPON-TYNE.

It is pleasing to receive from Newcastle-upon-Tyne a report of a Committee of the Corporation upon a proposed new sanitary hospital containing provision for small-pox as well as other infectious diseases, but which does not appear to be hampered with the difficulties of site we have to contend with in the metropolis.

It would appear from a statement of Mr. Henley, of the Local Government Board, at a recent meeting of the Reading Board of Guardians, that small-pox is beginning to extend from the metropolis into the neighbouring districts. Cases are recorded at Guildford, Staines, and Windsor, on the one side, and Aylesbury on the other.

The Jarrow Town Council appears to have got into some difficulty with the medical men in the town, in which its medical officer of health is concerned, respecting the carrying out of some of the provisions of its Local Act affecting infectious diseases.

The Aylesbury Local Board of Health have declined to act upon a suggestion of the Local Government Board that they should combine with the Rural Sanitary Authority in the election of a medical officer of health.

The Fulham Guardians have consented that the District Board shall have certain detached buildings under their control for use as temporary small-pox hospitals, if required

It would appear that certain of the London boards of guardians "contract" for their ambulances, and we hear of children playing about the parish ambulances in one of the mews in St. George's, Hanover-square!

The magistrate at Worship-street has imposed a fine of 10*s.* with 2*s.* costs upon a woman for removing from her house to another house, without previous disinfection, a bed on which a person had died from "fever."

The *Metropolitan* gives currency to a rumour that the Metropolitan Asylums Board will, in consequence of the recent decision in the House of Lords, resign in a body.

The loitering of ambulances in the streets on their return from the metropolitan infectious disease hospitals is occupying the attention of the Asylums Board.

A case is reported from Lambeth of a woman, a milk-dealer, continuing to attend to her business while in attendance upon a child suffering from small-pox.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality continues satisfactorily low compared with the average rate for the season. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5829 births and 3357 deaths were registered last week. The births exceeded by no less than 653 and the deaths by 100, the average weekly numbers during 1880. The deaths showed a further increase of but 2 upon the low numbers returned in the two previous weeks, and were equal to an annual rate of 23·0 per 1000; in the two previous weeks the rate was equal to 21·9 and 23·0. The lowest death-rates in the twenty towns last week were 15·8 in Brighton, 18·7 in Bradford, 19·3 in Sunderland, and 21·0 in Hull. The rates in the other towns ranged upwards to 26·6 in Oldham, 26·7 in Liverpool, 27·8 in Leeds, and 28·8 in Manchester. During the past ten weeks of the current quarter the death-rate in the twenty towns averaged 24·6 per 1000, against 25·7, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 290 and 296 in the two previous weeks, further rose to 311 last week; these included 84 from whooping-cough, 63 from scarlet fever, 59 from small-pox, and 33 from fever, principally enteric. The annual death-rate from these principal zymotic diseases averaged 2·1 per 1000 in the twenty towns, and ranged from 0·5 and 1·2 in Brighton and Norwich, to 2·7 in Leicester and Newcastle-upon-Tyne, and 3·1 in Oldham. Whooping-cough showed the largest proportional fatality in Nottingham, Manchester, and Leeds; and scarlet fever in Oldham, Leicester, Bristol, and Norwich. Nine of the 12 deaths from diphtheria in the twenty towns occurred in London. The death-rate from fever was again generally low, but showed an excess in Salford, Newcastle-upon-Tyne, and Leeds. Small-pox caused 60 more deaths in London and its outer ring of suburban districts, one in Manchester, and not one in any of the nineteen other provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased in the nineteen preceding weeks from 77 to 779, further rose to 792 on Saturday last. The new cases of small-pox admitted to these hospitals, which had increased from 176 to 195 in the four previous weeks, were 180 last week. The Highgate Small-pox Hospital contained 60 patients on Saturday last, showing a further increase upon the numbers at the end of recent weeks; 25 new cases were admitted to this hospital during last week.

The deaths referred to diseases of the respiratory organs in London, which had been 367 and 419 in the two preceding weeks, declined again to 384 last week, and were 70 below the corrected average number in the corresponding week of the last ten years; 242 resulted from bronchitis, and 91 from pneumonia. The annual death-rate from lung diseases (excluding phthisis) was equal to 5·4 per 1000 in London last week; the rate from the same diseases in Liverpool was 8·1.

The causes of 81, or 2·4 per cent., of the deaths in the twenty towns last week were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths did not exceed 1·1 per cent. in London, while it averaged 3·6 per cent. in the nineteen provincial towns. No uncertified causes of deaths were registered last week in Portsmouth, Norwich, Plymouth, and Newcastle-upon-Tyne; while their proportion was largest in Salford, Hull, and Oldham.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate averaged 23·4 per 1000 last week, against 22·5 and 22·9 in the two preceding weeks; this rate was 0·4 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 17·2 and 20·2 in Leith and Edinburgh, to 27·5 and 31·2 in Paisley and Perth. The deaths referred to the principal zymotic diseases in the eight towns, which were 70 and 83 in the two previous weeks, were 82 last week, and included 31 from whooping-cough, 13 from diarrhœa, 13 from diphtheria, 11 from scarlet fever, 10 from "fever," 4 from measles, and not one from small-pox. The annual death-rate from these zymotic diseases was equal to 3·2 per 1000, and was 1·1 above the average rate from the same diseases in the twenty English towns; this zymotic rate in the eight Scotch towns last week ranged from 0·0 and 1·1 in Perth and Paisley, to 3·7 and 5·2 in Glasgow and Leith. The fatal cases of whooping-cough in the eight towns, which had been 17 and 28 in the two previous weeks, further rose to 31 last week, of which 15 occurred in Glasgow, 7 in Dundee, and 4 in Leith; the fatal cases in Edinburgh showed a considerable decline. The 13 deaths referred to diphtheria were fewer by 5 than the number in the previous week; 8 occurred in Glasgow and 2 in Leith. The 13 fatal cases of diarrhœa included 5 in Glasgow and 3 in Edinburgh. Of the 11 deaths from scarlet fever 7 were returned in Glasgow and 3 in Edinburgh. The deaths referred to "fever," which had been 14 and 6 in the two previous weeks, rose again to 10 last week, of which 5 occurred in Glasgow, 4 in Edinburgh, and 1 in Paisley; the annual death-rate from "fever" in the Scotch towns was last week nearly twice as high as the average rate from the same cause last week in the twenty English towns. The deaths referred to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy), which were 150 and 179 in the two preceding weeks, declined again to 168 last week, and were equal to an annual rate of 6·7 per 1000; the rate from the same diseases in London did not exceed 4·5 per 1000. The largest excess in the fatality of lung diseases in the Scotch towns occurred last week in Glasgow, Dundee, and Paisley.

HEALTH OF DUBLIN.

Although slowly decreasing, the rate of mortality in Dublin continues excessive. The annual death-rate in the city, which had slowly but steadily declined from 47·4 to 36·0 in the six preceding weeks, further fell to 33·8 last week. During the past ten weeks of the current quarter the death-rate in the city has, however, averaged no less than 39·5 per 1000, against 24·1 in London and 22·7 in Edinburgh. The 216 deaths in Dublin last week showed a further decline of 14 from recent weekly numbers, and included 23, or rather more than 10 per cent., which were referred to the principal zymotic diseases, against 31, 24, and 21 in the three previous weeks. These 23 deaths from zymotic diseases included 10 from fever (including typhus, enteric or typhoid, and simple continued), 5 from diarrhœa, 3 from scarlet fever, 2 from diphtheria, 2 from whooping-cough, 1 from measles, and not one from small-pox. The annual death-rate from these zymotic diseases was equal to 3·6 per 1000 in Dublin last week; it was only 2·3 in London and was 2·9 in Edinburgh. The deaths referred to fever, which had been 17, 10, and 8 in the three preceding weeks, were again 10 last week; these were equal to an annual death-rate seven times as high as the average rate from the same causes last week in the twenty large English towns. The fatal cases of diarrhœa were more numerous, while those of scarlet fever and whooping-cough showed a decline from recent weekly numbers. The 2 deaths from diphtheria also exceeded the numbers returned in recent weeks. The deaths of infants were fewer than in any previous week of this year, and the deaths of elderly persons showed a further decline from recent weekly numbers.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

TRICHINIASIS.

The Local Government Board have held it advisable to issue a circular to sanitary authorities, together with a memorandum prepared by their medical officer, Dr. Buchanan, on the subject of trichiniasis (although the Board have no information of the present existence of the disease in Great Britain, and trust that its prevalence is not to be apprehended). The circular directs attention to this disease in connexion with the consumption of the imperfectly cooked flesh of pigs infested with trichinæ, and suggests increased vigilance on the part of medical officers of health and inspectors of nuisances in carrying out their instructions with regard to diseased, unsound, or unwholesome meat. The memorandum briefly sets forth the precautions requisite to be taken to obviate the danger which may be feared from any accidental use of pig's flesh which may chance to be infested with trichinæ. "Inasmuch," it says, "as the meat infested with these worms cannot be recognised by any popular test, and the worms themselves can only be detected by careful microscopic examination, it becomes important to take precautions against harm to man in the case of meat from all pigs. The only known means of avoiding disease in man from this dangerous quality of meat from pigs is by very thorough and efficient cooking. If there is reason for thinking a particular sample of meat to contain the parasites it ought not, on any account, to be eaten, no matter how it is cooked. Hams, sausages, and like articles, whether or not they have been smoked or salted, should never be eaten in the raw state. To be efficient for the required purpose the cooking of pork, of hams, of bacon and of other articles, should be prolonged for about half as much time again as is customary. The smallest joint should be cooked for not less than an hour; and whatever be the size of the joint, it should have not less than half an hour's cooking for each pound of meat. No part of a joint that is seen to have an underdone portion in it should be eaten. In boiling hams and pork, the meat should be put into cold or lukewarm water, and the period of cooking should be reckoned *from the time when the water boils.* In boiling several joints of pork or several hams (as required at institutions and elsewhere), they should not be put together in bulk at the same time into the same cooking vessel. Each joint should be put into a separate vessel, and boiled with a good quantity of water. Though the caution is not given for the avoidance of the particular diseases here in question, the present is a useful opportunity to mention that it is of much importance to health to see that larders, and places where cooked meat is stored, are kept always clean and free from the chance of foul air entering them. Serious outbreaks of disease are appearing with some probability to be related to neglect of this precaution."

THE REPORT OF THE NATIONAL BOARD OF HEALTH, U.S., FOR 1880.

The annual report of the National Board of Health, U.S., for 1880 shows a large amount of excellent work, scientific and other, done during that year, and gives good promise that the objects sought to be secured by the promoters of the Board will be fully secured. The United States of America form a big country, and it will require time before local jealousies can be wholly overcome and before the *national* aim of the Board, as distinguished from the *local* efforts of particular States, will be thoroughly apprehended. Nothing could well contribute better to smooth any friction arising from State jealousies and over-sensitiveness than the account of the work done by the Board in 1880. It is work in which the United States may well take a *national* pride, and which will presently place the National Board in the fore-front of those bodies which exercise the greatest influence in the hygienic progress of the human race. The mere list of work done by the Board in 1880 is too long to admit of a place here, and happily the United States is so generous in distribution of the bulletins of the Board that the recapitulation is unnecessary.

THE SERVICES.

THE BATTLE OF LAING'S NEK: GENERAL COLLEY'S DESPATCHES.

It is gratifying to record that in the despatch describing the action of Laing's Nek on the 28th of January, the late gallant Commander-in-Chief in the Transvaal does not forget the valuable services rendered by the Medical Department. The following extract from his report will be noted with much interest:—"Surgeon-Major Babington was in charge of the field hospital, and laboured zealously and untiringly to meet the heavy calls made upon him and his medical staff. (Surgeons E. King and J. McGann, A.M.D., and Surgeon E. E. Mahon, R.N., Her Majesty's ship *Flora*, distinguished themselves by their attention to the wounded under fire.) The ambulances were formed close in rear of the position taken up, and were soon crowded with wounded; but through the great exertions of Surgeon-Major Babington and his assistants, with ready help from the transport and the regiments, the wounded were all cared for and brought into camp before night."

The Right Hon. the Secretary of State for War has presented a silver medal to Surgeon J. M. Giles of the Indian Medical Service, the winner of the Herbert Memorial prize at the last session of the Army Medical School, Netley. Mr. Giles obtained the first place in the competitive examination for commissions in the Indian Medical Department.

Deputy Surgeon-General Thompson, Bombay Medical Service, has been appointed Principal Medical Officer, Southern Afghanistan Field Force, vice Deputy Surgeon-General Bruce.

Surgeon-Major R. Hare, Surgeons G. H. K. O'Callaghan and B. T. MacCreery embarked for India in H.M. troopship *Serapis* on the 17th inst.

Surgeon-Major G. White embarked on board the *Persian Monarch*, on Wednesday, for the Transvaal, in medical charge of troops.

Surgeon General Thomas Longmore, C.B., Professor of Military Surgery in the Royal Victoria Hospital, Netley, has been granted the vacant pension of £100 a year for distinguished and meritorious service.

India Office.—The Queen has approved the following retirements from the service of the undermentioned officers:—Surgeon-Majors William John Palmer, M.D., and Archibald Macdonald Garden, of the Bengal Army; Surgeon James Atkinson West Spence, of the Madras Army; and Surgeon Daniel Henry Cullimore, of the Madras Army.

It is announced from Calcutta that the Government has sanctioned the formation of a native army hospital corps, to be established on a footing similar to that on which the English army hospital corps is based.

Admiralty. — The following appointments have been made: Staff Surgeon James Robinson to the *Ranger*; Surgeon G. T. O'Grady to the *Egeria*, vice Cann; Staff Surgeon Robert Turner to the *Duke of Wellington*, in lieu of a surgeon; Staff Surgeon James Bradley to the *Asia*, in lieu of surgeon, vice M'Ivor; Staff Surgeon George B Murray to the *Swift*, when commissioned; Surgeon Richard J. Barry to the *Indus;* Surgeon John Wood to the *Audacious*, vice Robertson.

INTERNATIONAL MEDICAL CONGRESS, 1881.

Museum Section.

A temporary museum will be opened during the sittings of the Congress in the rooms of the Geological Society. All objects of novelty or rarity having reference to the processes of disease or the results of injury will be acceptable for exhibition. The committee in charge of it will be especially obliged by the loan of drawings, photographs, and models, for the efficient display of which careful arrangements will be made. They will be glad to receive and exhibit all preparations and drawings used for the illustration of papers in the various sections, or having reference to the subjects discussed. There will be an exhibition of living examples of certain rare diseases. Arrangements will also be made for the exhibition of a limited number of microscopic objects. In most instances it will perhaps be found convenient for the exhibition of special series to take place at fixed times, previously arranged and announced, at which the exhibitor will probably attend to give explanations. All communications regarding the museum are to be addressed to the Secretary of this Section—Mr. H. H. Clutton, 16, Palace-road, St. Thomas's Hospital, S.E.

The Children's Hospital, Great Ormond-street.—Lord Aberdare presided on Wednesday at the twenty-ninth anniversary of this institution, held at Willis's Rooms. A large and distinguished company assembled on the occasion, and over £2000 were collected. The committee are desirous, as soon as sufficient funds are forthcoming, to complete the plans originally designed by the late Mr. Barry, by which an addition of eighty beds would be effected.

MEDICAL NOTES IN PARLIAMENT.

Prevention of Floods.

IN the House of Lords on Thursday (10th) their lordships went into Committee on the Rivers Conservancy and Floods Prevention Bill, which had been considered by a Select Committee. Certain amendments proposed by Lord Spencer, who has charge of the measure, were agreed to by their lordships. One of them had for its object to enable the District Inspector or the Local Government Board to entirely exclude a district from taxation by way of contribution to the drainage. An amendment proposed by Lord Carrington, for the relief of middle and low lands, was rejected. A new clause, moved by Lord Spencer, to enable conservancy boards to construct works for arterial drainage and for the storage of water, as subsidiary to the objects of the Act, was so much objected to in discussion that the noble earl ultimately withdrew it. Lord Jersey proposed, in Clause 19, an amendment to alter the incidence of taxation from the plan laid down in the clause; but, after some discussion, it was negatived without a division. This, and the remaining clauses, having been agreed to, the Bill passed through Committee, and was reported, with amendments, to the House.

On Tuesday the report of amendments on the Alkali, &c., Works Regulation Bill was received, after another protest by Lord Midleton against the insufficient character of the measure. The report of amendments on the Rivers Conservancy and Floods Prevention Bill was also received.

In the House of Commons on Thursday, the 10th inst., Mr. Massey, chairman of the Select Committee on the Contagious Diseases Acts, reported that, in the opinion of the Committee it was desirable that Dr. Farquharson and Dr. Cameron should be added to the Committee. Subsequently Mr. Childers moved that it was agreed to enlarge the Committee by adding those two hon. gentlemen.

On Monday a petition for inquiring into the East India Army Medical Department was presented from Joseph J. Monteath. The twenty-second report of the Board of Superintendence of the Dublin Hospitals was presented.

Vivisection.

Mr. Pease gave notice that on Thursday he would move an address for copy of any report from the inspectors, showing the number of experiments performed on living animals during the year 1880, under licences granted under the Act 39 and 40 Vic., c. 77, distinguishing painless experiments from painful experiments (in continuation of Parliamentary Paper, No. 125, of Session 1880).

Vaccination in Prisons.

Mr. Yorke asked the Secretary of State for the Home Department whether the medical officers of Her Majesty's prisons are required by the regulations to vaccinate all children born in the prisons before they are allowed to go out; and, if so, whether such regulations are strictly enforced, especially in the case of the female prison at Westminster. Sir W. Harcourt said there was no absolute rule on the subject, nor could there be. It was uncertain at what age a child might be when the mother was discharged. As a general rule, a child was vaccinated in prison when it was old enough, and the mother made no objection. The answer he had received to an inquiry was, that all of the children born in Westminster prison were vaccinated if they were old enough, and not too delicate.

Fever and Small-pox Hospitals.
